**Table 1: Recursive structure of a teaching-practice**

## The design of a practice

The mission of the PRAQTAL project is not just to identify and document quality teaching practices, but also to make those available to pre- and in-service teachers. For this purpose, we

develop an accessible presentation of practices which is communicative and appealing to practitioners.

On our website, we present practices as tri-partite structure, described in Diagram 1.

**Diagram 1: The tri-partite structure of a teaching practice**

## Discussion

In this paper we presented the initial work of project PRAQTAL. We began this account with our personal paths into the domain of teaching practices, and noted how these resonated with a general trend in educational research and teacher training. Most of the work in the field focuses on deriving practice recommendations from theoretical frameworks and developing teacher training programs based on these. Our approach was to first move beyond the intuitive treatment of the core concepts, and systematically define the constructs of *teaching-practice* and *quality-teaching-practice*, based on the commognitive conceptual framework. We adopt commognition for three main purposes: (1) for the conceptualization of our basic terms, such as: “practice” and “quality teaching practice”, (2) to develop a methodology for discourse analysis of transcripts of mathematics lessons that helps us identify teaching practices, and (3) findings from commognitive studies serve as main literature from which we identify possible teaching practices that we then look for empirically (an example is teaching practices that promote meta-level learning, a commognitive idea that we continue to develop in the field of teaching practices. This is beyond the scope of this paper). On these foundations, we proceeded to formulate a methodology for sourcing, articulating and communicating practices. Our methodology blends discourse analysis and design based traditions in mathematics education research, and the standard of quality stems from a commognitive framework. We illustrate this methodology through an example. At this stage, we have the building blocks for a combined scientific and pragmatic inquiry into the teaching practices of mathematics. The next steps are to build an extensive language of practices, validated empirically and theoretically, and map the connections between them. In parallel, we will develop our framework for practices-oriented teacher training. True to our constructivism roots, we reject the urge to “deliver knowledge of practices” to teachers and teachers in training, and instead aim to base our offering on co-construction and critical discussion of representations of practices. We invite the community to join us in these endeavours.

## Acknowledgement

The PRAQTAL project reported in this study is supported by the Trump foundation, grant number 235. The ideas voiced in the paper are a result of discussions among PRAQTAL team which include the authors and Roni Mualem, Avital Elbaum-Cohen and Sara Haupt, and the advisors: Anna Sfard and Shulamit Kapon.

# A lens on two classrooms: Implications for research on teaching

Siún Nic Mhuirí

Dublin City University, Ireland; [Siun.NicMhuiri@dcu.ie](mailto:Siun.NicMhuiri@dcu.ie)

*This paper uses the Teaching for Robust Understanding framework (Schoenfeld, 2013) as an analytic lens on episodes of mathematics teaching from two different countries. This lens highlights differences in teaching approaches across the two settings and draws attention to the need for further interrogation of how culture, curriculum and values inform teaching practices. It also has implications for research practices as it shows that the theoretical frameworks and methodological tools that are used in research are not value free or culturally neutral.*

**Keywords:** Research frameworks, culture, international, mathematics teaching.

## Introduction

My motivation in writing this paper is to address some of the questions that were raised in TWG19 at CERME10. I hope to contribute to discussions on methods used to conduct research on mathematics teaching. I have a particular interest in how research frameworks are used by different communities. At CERME10, I presented a view of research frameworks as theoretical frameworks or methodological tools which ‘frame’ or structure a coherent set of understandings about a theme (Nic Mhuirí, 2017). In this paper, I use the Teaching for Robust Understanding (TRU) framework (Schoenfeld, 2013) to analyze segments of mathematics lessons. I raise questions about how culture, curriculum and values inform teaching practices and how research frameworks reflect this (or not). I conclude by considering the implications for research practice more generally.

## Theoretical Framework

I situate my work in the sociocultural perspective where learning is conceived as transformation of participation in social practices (e.g., Lerman, 2001). From this perspective, a classroom community can be understood as a community of practice (CoP) (Wenger, 1999). The CoP theory developed from research on apprenticeship contexts. Critics argue that it does not offer a theoretical base for formal teaching where teachers are accountable for learning outcomes (e.g., Goos & Bennison, 2008). Attention to teacher as agent for educational and social change (Cochran-Smith & Lytle, 2009) is necessary to envisage how new practices might come to be established within the community. Notwithstanding student agency and the influence of the wider sociocultural context, the teacher is assumed to have agency, and generally some authority, in choosing actions which shape the practices of classrooms, i.e., “the repeated actions in which students and teachers engage as they learn” (Boaler, 2002, p. 113). However, teaching is more than simply a collection of practices. Following Biesta and Stengel (2016), I recognize teaching as relational, intentional and purposeful. Firstly, teaching implies a relationship between the person teaching and the one being taught. The teacher also has a role to play in ‘relationally bridging’ student and subject (Grootenboer & Zevenbergen, 2008). While learning may occur, in the absence of teaching, teaching is considered to be intentional as teachers deliberately aim to teach their students. Furthermore, education is a “teleological practice where the question of what education is *for* can never be evaded” (Biesta & Stengel, 2016, p. 33, original emphasis).

Biesta and Stengel contrast ‘purpose’ with the more concrete ‘aims’ which a teacher might endeavor to achieve. They describe the purpose of education as concerned with justification for engaging in teaching and consider ‘purpose’ to be normative and indicative of what is ‘educationally desirable’ (2016, p. 31). They identify three important domains of educational purpose: qualification; socialization; and subjectification. Qualification is understood as connected with “the transmission and acquisition of knowledge and skills” and socialization is understood as “the way in which through education we become part of existing cultures and traditions and form our identity” (Biesta & Stengel, 2016, p. 26). Subjectification is “an educational orientation concerned with the ways in which human beings can be subjects in their own right, rather than objects of the actions and activities of others (2016, p. 21). It is difficult to argue with Mosvold and Hoover’s (2017) contention that “while there are other important aims of education, teaching is centrally about supporting the learning of subject matter” (p. 3111). However, Biesta and Stengel maintain that such aims should be articulated in relation to the domains of educational purpose.

The view of education proposed by Biesta and Stengel centralizes teacher agency as it highlights the role of teacher judgment. In every activity, teachers make (tacit) judgments about the balance between the three domains of educational purpose. This has connections with Schoenfeld’s (2015) theory of teachers’ decision-making. He maintains that for a well-practiced activity like teaching, decision making is a function of teachers’ knowledge, resources, goals, beliefs and orientations. His model of in-the-moment decision making offers a fine-grained lens on teacher judgments. By situating such judgments in the broader field of the three domains of educational purpose, Biesta and Stengel’s philosophy facilitates consideration of the bigger picture. It raises questions about how society, culture and curriculum shape teachers’ orientations and how beliefs about educational purpose influence everyday decision-making.

## Methodology

The data was collected by international researchers for different purposes. It was shared amongst TWG19 members who had expressed an interest in engaging in the analysis of common data at CERME10. Four pieces of data were shared, three of which contained video clips. I focused only on the video data which consisted of episodes from an American, a Greek, and a Norwegian classroom.

I will use the TRU Framework (Schoenfeld, 2013) for analysis. This framework consists of five dimensions: *the mathematics*; *cognitive demand*; *access to content*; *agency, authority and identity*; *uses of assessment*. *The mathematics* involves the disciplinary concepts and practices made available for learning. *Cognitive demand* aims to capture the extent to which students have opportunities to engage in ‘productive struggle’. *Access to content* addresses the extent to which activity structures support the active engagement of all students. *Agency, authority and identity* refers to the extent to which students have opportunities to instigate and contribute to discussions in ways that contribute to their agency, mathematical authority and to the development of positive identities. *Uses of assessment* relates to how classroom activities elicit student thinking and subsequent interactions respond to those ideas. Schoenfeld (2013) describes his goals in the creation of the framework as being concerned with identifying a relatively small but ‘complete’ number of categories of classroom activities for observation, i.e., no other categories or dimensions are thought

to be necessary for analysis. This claim of ‘completeness’ was the main reason for choosing to use the framework as a methodological tool. The TRU framework can be used for evaluation purposes but I aim only to highlight important issues and to interrogate the process of analysis itself.

The TRU approach to classroom observations separates or parses lesson by the nature of the activity structure that occurs: *Whole class activities* (including *topic launch*, *teacher exposition*, and *whole class discussion*); *small group work*; *student presentations*; and *individual student work*. Each episode should be relatively short but ‘phenomenologically coherent’ (2013, p. 617). The TRU framework contains detailed rubrics for all five dimensions across each of these activity structures. It might be considered that these activity structures are relatively unambiguous and should be easily recognized across international classrooms, e.g., individual work or small group work. However, issues of curriculum and culture should not be ignored (Andrews, 2011). For example, the activity structure ‘*topic launch*’ would seem to have strong connections to the ‘Launch-Explore-Summarize Teaching Model’ used in the US based Connected Mathematics Project Curriculum (<https://connectedmath.msu.edu/>). The extent to which this model of instruction is recommended by, or embedded in, other jurisdictions internationally is questionable. It is also possible that other important activity structures exist locally that are not captured in the TRU framework (c.f., Clarke et al., 2007). Despite these concerns, it was possible to categorize the data using the TRU activity structures so it was decided that it was appropriate to proceed with analysis.

To some extent the data was ‘pre-parsed’ as only selected elements of the lessons were shared. There were a variety of activity structures in evidence across the different classroom. The activities in the Greek classroom were conducted in a whole class setting with some elements of teacher exposition and whole class discussion. The activity structures in the Norwegian classroom involved a whole class topic launch, small group work/individual work and a series of student presentations. The activity in the US classroom centered on a single student presentation. Given the constraints of this paper, I decided to focus on the student presentations across the US and the Norwegian data. An overview of the data is shown in table 1.

US Data	Norwegian Data
Summer program for 5 <sup>th</sup> graders. Majority low SES participants. Experienced teacher recognized as expert (Professor Deborah Ball, University of Michigan) Video clip (c. 3 minutes) and contextual information.	Small group (5 students) primary teaching. Experienced teacher recognized locally as expert Video clip (c. 21 minutes) with English subtitles and transcription.

**Table 1: Overview of data**

### Overview of video content

In the US video, a student presents a solution to a task concerning what fraction is marked on a number line. She gives the incorrect answer of  $\frac{1}{7}$ . Her justification is that there are seven equal parts shown on the number line. The teacher invites students to question her reasoning.

In the Norwegian example, the teacher gives the students the task of figuring out what year the King was born. In effect, students have to compute  $2017 - 80$ . After about 5 minutes, the teacher asks students to present their solution methods. These are summarized below.

- *Presentation 1:*  $80 - 17 = 63$ ,  $2000 - 63 = 1937$ . The calculations were carried out using the standard algorithm even though the procedure has not yet been taught for higher number ranges. The teacher models the students' thinking on an empty number line and also models the algorithm.
- *Presentation 2:*  $2000 - 80 = 1920$ ;  $1920 + 17 = 1937$ . The calculations were done mentally but recorded in vertical format at the board.
- *Presentation 3:*  $2017 - 80 = 1937$  using standard algorithm.
- *Presentation 4:*  $1900 + 20 = 1920$ ;  $1920 + 17 = 1937$ . Teacher questioning appears to aim to expose reasoning.
- *Presentation 5:* The first student complains that she did not have a chance to write her method (standard algorithm) on the board. Teacher invites her to do this.

## Results

Due to space limitations the full TRU framework rubric for student presentations is not presented here. Instead, under each heading, I give a brief overview of all levels with a full description of the most relevant levels (in italics). I then present an analysis of relevant classroom events.

### The Mathematics

*Level 1 (answers without reasons) and Level 2 (procedural mathematics with no expectation of reasoning) do not apply in either case. Level 3 is described as follows: The Mathematics presented is relatively clear and correct AND either includes justifications and explanations OR the teacher encourages students to focus on central mathematical ideas and explaining and justifying them.*

In the US classroom, explanations were given by the presenter Aniyah but the mathematics was incorrect. The teacher encouraged other students to ask questions but not to evaluate (i.e., agree or disagree with) her solution. Toni questioned why she chose one-seventh. Lakeya questioned her choice of 1 for the numerator. Dante's question is unclear but may also be targeting the numerator. The focus on justification and key mathematical ideas would place this at level 3 of the rubric.

In the Norwegian classroom, the mathematical reasoning was correct and the explanations were generally clear (level 3). Where this was not clear (e.g., presentation 4), the teacher asked clarifying questions. In presentation 5, the student inverted the numbers when writing the standard subtraction algorithm. She appeared to recognize her own error and the teacher said he understood her thinking. He appeared to value reasoning above procedures. All presentations can be described by level 3.

### Cognitive Demand

*Level 1 (familiar facts and procedures) does not apply to either case. Level 2: Presentation offers possibilities of conceptual richness or problem solving challenge, but teaching interactions tend to 'scaffold away' these possibilities, resulting in a straightforward or familiar focus on facts and procedures. Level 3: The teacher's hints or scaffolds support presenters and/or class in 'productive struggle' in building understanding and engaging in mathematical practices.*

In the US classroom, the mathematics was cognitively demanding for the presenter Aniyah and perhaps for others, e.g., Dante. Other students were invited to ask questions and in this way possibly provide support for Aniyah. The extent to which these interactions were ‘productive’ for her and/or other students is not obvious on completion of the clip. Level 3 most closely describes this extract but it was the classroom community, rather than the teacher, that was providing the scaffolding.

The task in the Norwegian classroom was of appropriate challenge. One student solved it quickly but others needed more time and one student did not come to a correct solution. In presentation 1, the student was clear in her ideas but this transitioned quickly to teacher explanation. The second student presented a mental method. Again, the teacher took responsibility for explaining this. No scaffolding occurred in presentation 3. It might be considered that a more challenging example of the standard algorithm had been addressed in presentation 1. This might explain why the teacher did not dwell on this example. The teacher’s questions in presentation 4 appeared to attempt to scaffold the presenter and clarify her ideas. Across all presentations, the focus remained on student thinking rather than procedures. However, the teacher’s actions are closer to level 2 than to level 3. While presenters did not often need the teacher’s support, his input may have the effect of ‘scaffolding away’ the opportunities for students to build their own understanding of each other’s ideas.

### **Access to Mathematical Content**

*The descriptions for this dimension refer to teacher-presenter conversations (C) and whole class discussions (W). Level 1 (no support (C) or significant disengagement (W)) and level 2 (ineffective scaffolding (C) or uneven participation without teacher action (W)) do not apply. Level 3: Teacher supports presenters if needed (C) or the presentation evolves into whole class activity in which the teacher actively supports broad participation and/or what appear to be established participation structures result in such participation (W).*

The US classroom was very much orientated to the whole class situation (W). Not all students contributed to this discussion but the teacher deliberately orchestrated whole-class consideration of Aniyah’s idea. This is indicative of level 3 of the framework.

In the Norwegian classroom, the interaction was between the teacher and each presenter in turn (C). The teacher asked clarifying questions. Some questions might be considered to be dual-purpose in that the other students might have benefitted from them. However, the discussion never ‘evolves into whole class activity’ (W) and the students were not explicitly asked to comment on each other’s ideas or to make connections across suggestions. It is hard to match this with TRU framework descriptions as for teacher-presenter conversations (C) level 3 still refers to active supporting of presenters (which was only necessary in presentation 4).

### **Agency, authority and identity**

*Level 1 (presentation constrained by teacher questions) does not apply. Level 2: Presenters have the opportunity to demonstrate individual proficiency but the discussions do not build on student’s ideas. Level 3: Student presentations result in further discussions of relevant mathematics or students make meaningful reference to other students’ ideas in their presentations. (To qualify as an idea what is referred to must extend beyond the tasks, diagrams etc. that is referred to)*

In the US classroom, Aniyah's presentation appeared to launch some classroom discussion of meaningful mathematics. This would place it at level 3 of the framework. It can be argued that students such as Toni take on an evaluative role. She acts as a mathematical authority and demonstrates agency. Such activities are envisaged to contribute to positive mathematical identity. The nature of Aniyah's experience is less clear and at the end she chooses to sit down rather than continue presenting/defending her idea. It is necessary to track participation over a longer period before one can make any claims about identity or agency (Nic Mhuirí, 2014).

The Norwegian classroom can technically be considered at a level 3 but while students are the source of ideas, they are not the source of discussion. Talk is teacher-led at all times. Student contributions are reformulated and explained by the teacher presumably for the purposes of ensuring others understand. Consequently the teacher retains mathematical authority. He also 'rates' the solution strategies of two students. After presentation 3, he first praises the girl who used the standard algorithm. Then he compares it to the previous presentation, saying "But his way to do it, I'd say, uses a method that's easy to calculate in your head. Really smart." By implication, the solution using the standard algorithm in a number range students have not officially been taught yet, is positioned as not as 'smart.' This hierarchical positioning of solutions, and by implication students, does not occur anywhere else but it does speak to issues of identity and authority.

### **Use of Assessment**

*Level 1 (reasoning not pursued) and level 2 (specific student ideas not utilized) do not apply. Level 3: In presentation and discussion, the teacher solicits student thinking and responds to student ideas by building on productive beginnings or addressing emerging misunderstandings.*

The US classroom episode is aligned with the level 3 description and might be considered formative assessment in action. The teacher is activating the other students to respond to Aniyah's misunderstanding. It would be necessary to see how this plays out to judge whether the strategy is effective for Aniyah and other students.

In the Norwegian classroom, the teacher emphasizes student thinking. In presentation 1, the teacher uses the student's ideas as a launch to model her solution on an empty-number line and to model the standard subtraction algorithm. This episode might be considered to 'build on productive beginnings' (level 3). Levels of understanding were not generally made explicit in the classroom dialogue. The teacher posed a question which explicitly sought to assess students' understanding just once. It is possible that in this small group the teacher could closely observe indications of student (mis)understanding. Late in the episode, (c. 18 minutes) a student explained that he had attempted to solve the task using the standard algorithm but had gotten an incorrect answer. It remains unclear whether he learned how to complete this correctly from the class dialogue.

### **Discussion**

On an evaluative level, the short US video scored higher on the dimensions of the TRU framework than the Norwegian example. The analysis showed differences in the extent to which agency was devolved to students. This devolution was carefully orchestrated by the teacher in the US classroom. Student presentations never evolved into whole-class discussion in the Norwegian

setting. All interactions were funneled through the teacher and it was never explicitly stated that the students should attempt to understand each other's reasoning though this may have been an implicit teacher expectation. Such norms were possibly well established in comparison to the US summer school where the teacher was working to establish norms. Indeed, when the Norwegian students were working on developing solutions, they displayed some annoyance that one of the participants indicated the answer before all had completed working. In one of his only explicit directions, the teacher gave the following instruction: "A good tip right now is not to trust that one sitting beside you [...] you can only trust yourself. Think for yourself and trust yourself." This appears to emphasize individual effort and indicates an expectation that all students should be able to devise a solution independently. Individual thinking, including errors, was valued in the US classroom but the teacher also seemed to be trying to set an expectation that the community should support the individual in making sense of mathematics. It might be argued that particular forms of socialization and subjectification (Biesta & Stengel, 2016) were being actively pursued by the US teacher.

The extent to which certain forms of socialization and subjectification are interwoven into the TRU framework warrants further attention. The framework presents a leveled or hierarchical positioning of various teacher practices that is not value-free. For example, in the Access to Mathematical Content dimension, two different participation structures are recognized: teacher-presenter conversations and whole-class involvement. In the Norwegian classroom, it appears that teacher-presenter conversations occur for the benefit, but without the involvement, of the whole-class. This participation structure is not recognized by the TRU framework but has some similarities to Andrew's (2011) discussion of the 'implicit didactics' of Finnish classrooms where teachers' extended conversations with a competent child in a whole-class setting appeared to be a common feature. These embedded, but unspoken, expectations raise particular challenges for researchers.

Any research lens is informed by the values of the researcher and the research tradition from which the lens is drawn. Often what is valued by a lens remains implicit and unexplored. In this case, the disconnection between the TRU framework and the Norwegian classroom highlights something about the lens itself. This disconnection also raises questions about culture, and whether it is suitable to use a framework developed in one environment to analyze teaching in a different context where conceptions of expert practice may be quite different (Clarke et al., 2007). The aim of this paper however was not to compare teachers (or contexts) but to explore some of the challenges of conducting research in mathematics education. Limitations to this research include the length of the US video and the outsider-status of the researcher in relation to both contexts. The analysis of the Norwegian data was conducted with an English transcript and it is likely that particular nuances of language and meaning have been lost in translation. However, this brief analysis does draw attention to the need for further interrogation of how culture and values inform teaching practices and research frameworks.

# Assessing how teachers promote students' metacognition when teaching mathematical concepts and methods

Edyta Nowińska

A. Mickiewicz University in Poznan, Poland; [nowinska@amu.edu.pl](mailto:nowinska@amu.edu.pl)

*An important aspect of teaching mathematics is designing learning environments and guiding students' learning activities in such a way that learners can develop or improve their mathematical competencies. Promoting students' metacognition in teaching mathematics is regarded as having an important role in achieving this goal. Unfortunately, rarely anything is known about how metacognition can be effectively fostered in regular mathematics classes. The paper presents an analysis and an assessment of metacognitive activities practiced in a regular mathematics lesson. It also describes the rating system used for this assessment, and exemplifies how this tool can be used to analyze the extent to which teacher's practices are conducive to foster students' metacognition, as well as to describe the need for a further improvement of these activities.*

*Keywords: Metacognition, instructional quality, classroom discourse.*

## About the role of metacognition in teaching and learning mathematics

In mathematics education, metacognition is usually understood as knowledge about cognition and regulation of cognition (Veenman, Van Hout-Wolters, & Afflerbach, 2006; Willson and Clarke, 2004). Most definitions of metacognition differentiate between *metacognitive knowledge* (e.g. the person's knowledge about cognitive tasks in mathematics, about strategies to cope with these tasks, and about one's own competencies related to these tasks and strategies), *metacognitive skills* (e.g. the person's procedural knowledge for regulating one's own problem solving and learning activities) and *the execution of such skills in form of metacognitive activities* (for an overview see Veenman et al., 2006). Such differentiation is important for theoretical considerations concerning the meaning of metacognition, whereas in concrete situations it is hardly possible to distinguish between these different components.

Metacognition has been ascribed an essential role in regulating students' cognitive processes in *problem solving*, but also in the *learning of mathematics in general*, in particular when constructing and organizing knowledge (cf. Schraw & Moshman, 1995; Wilson & Clarke, 2004), as well as in a *self-regulated use* of mathematics in different contexts in order to achieve some goals (Boekaerts, 1999). Thus, from a teachers' perspective, promoting students' metacognition can be considered as a *mean* for effective teaching – for engaging students in cognitive processes needed to understand the mathematical concepts and methods to be learned. But it must be also considered as a *goal* of teaching – as an essential aspect of students' mathematical competencies to be improved through teaching.

Much research has been done on modelling, analyzing and promoting metacognition in solving mathematical problems. Many paradigms adopted to this context in the past research were based on the assumption that the way students learn to solve problems is “to first acquire the mathematical knowledge needed, then acquire the problem-solving strategies that will help them to decide which already known procedure to deploy, then acquire the metacognitive strategies that will trigger the

appropriate use of problem-solving strategies (...).” (Lesh & Zwojewski, 2007, p. 793). Such paradigms not only separate problem solving from concept development. They also separate metacognition from teaching mathematical concepts and reduce promotion of metacognition to teaching a list of simple rules (e.g., make a plan, draw a picture, mark important words, control your solution, evaluate the result). I consider this separations as one possible reason for the unimpressive results (ibid.) from this kind of research, because it seems hardly possible to acquire adequate metacognitive knowledge for solving problems without being engaged in metacognitive processes when constructing substantial meta-mathematical knowledge, meaning knowledge about relevant mathematical concepts, methods, and reasoning strategies (cf. Veenman et al., 2006). And therefore I see the need for shifting the focus of research on metacognition from teaching problem solving to regular teaching situations in which the learners have to learn mathematical concepts and methods.

### **An operationalization of metacognition in teaching and learning mathematics**

Since rarely anything is known about how metacognition can be effectively fostered in class when teaching and learning new concepts and methods (cf. Wilson & Clarke, 2004), a deep analysis of metacognitive practices in regular classes can be the first step for research aiming at enhancing students’ metacognition. For this, an operationalization of the construct “metacognition” for the context of teaching and learning mathematics is needed. This has been done by the research group Cognitive Mathematics at the University of Osnabrueck. Its result is a category system<sup>1</sup> decomposing metacognition in *planning*, *monitoring* and *reflection*. Planning means organizing cognitive activities in order to achieve some goals as well as specifying cognitive challenges to be overcome (e.g., planning the use of mathematical methods and concepts to write a proof or planning the use of a particular strategy or representation to solve an equation). Monitoring means controlling cognitive activities and their results (e.g., controlling the validity of logical statements of arguments and the consistency of an argumentation or the validity and adequacy of tools and methods used in mathematical modelling or the correctness of meaning extracted from a mathematical text). Reflection means thinking about different aspects of cognitive activities involved in learning and understanding mathematics (e.g., analyzing relations between concepts, conceptions, misconceptions and external representations of mathematical concepts, analyzing the process of developing new mathematical concepts, analyzing mathematical concepts, methods and strategies with regard to the kind of problems and contexts for/in which they can be applied).

### **On the role of discourse in promoting metacognition**

Promoting metacognition in mathematics class does not mean teaching only one individual student how to organize, control and evaluate her/his cognition when learning and applying mathematical concepts and methods. It rather means organizing the teaching in such a way that as many as possible students are engaged in metacognitive activities. This can be achieved by establishing a *discursive* discussion culture with rules that force the students to control and regulate their own cognition and comprehension when other students or the teacher explain their ideas, solutions, conceptions or difficulties in understanding the discussed mathematical ideas. Such discursive culture implies that

---

<sup>1</sup> [www.mathematik.uni-osnabrueck.de/fileadmin/didaktik/Projekte\\_KM/Kategoriensystem\\_EN.pdf](http://www.mathematik.uni-osnabrueck.de/fileadmin/didaktik/Projekte_KM/Kategoriensystem_EN.pdf)

the teacher and the students precisely control what the classmates say, reflect on differences between various conceptions and reasoning strategies mentioned in the class, and use this reflection to regulate their own understanding. However, this can be practiced in an effective and beneficial way, only if the teacher and the students use class discussions to precisely explain their cognition and if they aim for a coherent discussion. Such discursive aspects of class discussion seem to be inevitable for promotion of metacognition in regular mathematics classes.

To analyze such kind of discursive practices in regular mathematics classes, the category system decomposing metacognition in planning, monitoring, and reflection (see footnote 1) also includes two categories for analyzing and coding the precision and coherence of class discussions: *discursivity* and *negative discursivity* (both are not in the focus of this paper; for details see Nowińska, 2016b).

## Research question

To deepen our understanding on how metacognition is practiced in regular mathematics lessons, 24 lessons videotaped in six classes have been analyzed and assessed with the rating system described in the next section. One research question in this explorative study was: Which implications can be drawn from these assessments to improve the instructional quality with regard to metacognitive activities? This paper presents some results from this research. It reveals and explores an alarming fact concerning metacognitive practices in a regular mathematical instruction, and explains the need for a further improvement of the metacognitive-discursive quality. In doing so, it contributes to the discussion about how metacognition can be effectively implemented into mathematical instructions.

In the following, to begin with, the tool used for analyzing and assessing metacognitive activities is presented. Afterwards, metacognitive activities in one class are analyzed with this tool in order to make the alarming aspect more “visible”.

## The rating system for assessing metacognitive-discursive instructional quality

To assess the extent to which metacognitive activities are used to elaborate mathematical concepts, methods, and students’ cognition related to them, one needs a reliable evaluation method which also takes into consideration the *discursive* aspects of the class discussion. Such a method has been developed at the University of Osnabrueck, and evaluated in cooperation with the German Institute for International Educational Research (DIPF) in Frankfurt. It is based on the application of two tools explained in detail in Nowińska (2016a). The first tool is the afore-mentioned category system for coding metacognitive and discursive activities of teachers and students in their utterances in public class discussions (PCD). The second is a rating system for an evaluation of *metacognitive-discursive* instructional quality (MDQ). This tool was presented at the Third ERME Topic Conference (Nowińska, 2016b), and the evaluation results concerning the reliability of the ratings at CERME10 (Nowińska & Praetorius, 2017). The wording “metacognitive-discursive” has been chosen to stress that metacognitive activities are analyzed together with discursive aspects of class discussion.

The rating system is a set of seven rating scales for assessing different aspects of the instructional quality of these activities. In the two-step rating procedure, the rater first watches the video and reads the transcript; thereby she/he interprets each verbal student’s and teacher’s utterance and codes metacognitive and discursive activities using the category system. In the second step, the rater

assesses the quality of these activities with regard to seven rating dimensions (quality aspects). Thereby she/he uses the video and the transcript with all codes for metacognitive and discursive activities set by her/him in the first step. Each rating dimension is given by an item called guiding question (*GQ*) and by a nominal rating scale consisting of several answering categories<sup>2</sup>. The answering categories describe in detail how the relevant quality aspects are reflected in the class discussion. Different answering categories describe qualitatively different situations. Their order on the rating scale is based on the increasing quality of the class discussion with regard to the particular quality aspects. The rater has to choose the answering category that best describes the situation given in a class. For reasons of space, in the following, only three of seven guiding questions are explained.

The *first GQ* regards the extent to which learners practice metacognition in PCD in an autonomous and elaborated way, and focus it on the mathematical content (e.g. concepts, conceptions, methods) to be learned. There are four answering categories to it. The first category says that metacognitive activities are carried out solely by the teacher, and/or no effort is made to foster students' metacognitive activities in order to elaborate the mathematical content and students' understanding of it. The fourth category says that the learners are autonomous in practicing metacognition and thereby they make efforts to elaborate and understand the mathematical content.

The *second GQ* focuses on justifications combined with metacognitive activities, and on the extent to which they are used to elaborate on the mathematical content and on students' understanding of it. It asks for the extent to which students combine their metacognitive activities with elaborated justifications in an autonomous way, and also for the extent to which such justifications and coherent global argumentations of the whole class seem to be important in the culture established in the class (and consequently fragmentary justifications have to be corrected). There are four answering categories graduated in an analogue way as these to the first *GQ*.

The *third GQ* puts the focus on a hypothesized learning effectiveness of metacognitive and discursive activities of students and the teacher. The rater has to assess the extent to which the metacognition she/he observed in the videotaped PCD contributes to construct or deepen students' meta-mathematical knowledge or to foster their meta-mathematical skills related to the mathematical content of the lesson (tasks, questions, tools, methods, reasoning, concepts, conceptions). The first answering category describes a PCD without any constructive use of metacognitive and discursive activities; the second says that only very few learners make efforts to deepen their meta-mathematical knowledge or to reflect on their meta-mathematical skills, but their metacognitive activities are not elaborated by the classmates or the teacher. The third and last answering category says that metacognitive aspects of the mathematical content are discussed in a constructive and elaborated way.

### **Analyzing and assessing metacognition in mathematical instruction**

The lesson analyzed in this paper was videotaped in one class in grade 7 in a German secondary school (Gymnasium) during the introduction to linear equations. Four lessons in this class were videotaped and analyzed with the rating system, and all of them feature the alarming aspect described

---

<sup>2</sup> [https://www.mathematik-cms.uni-osnabrueck.de/fileadmin/didaktik/Projekte\\_KM/GuidingQuestions.pdf](https://www.mathematik-cms.uni-osnabrueck.de/fileadmin/didaktik/Projekte_KM/GuidingQuestions.pdf)

in this paper. The term ‘alarming aspect’ is used here to emphasize some striking characteristic of the instructional quality of metacognitive and discursive activities of the teacher and of the students in lessons planned for an introduction of new mathematical concepts and methods. Due to the small number of lessons, the case of the lesson analyzed in this paper has to be used with caution. But since similar aspects were also observed in other classes, there seems to be a tendency for some similar teaching practices also in the case of other teachers/classes.

### The instructional context of the introduction of a new mathematical concept

To motivate the introduction of the term ‘equation’, the teacher uses two mathematical problems. One of them is: “The three major oceans (Pacific, Atlantic, and Indian Ocean) together have a water surface of 320 million square kilometers. The Pacific Ocean is twice as large as the Atlantic, and the Indian Ocean is 10 million square kilometers smaller than the Atlantic Ocean. The surface  $x$  (in million square kilometers) of the Atlantic is unknown.” The teacher makes no comments on the concept of equation to be learned in this lesson.

Solving this problem requires the use of metacognitive activities of planning a solution, controlling the solution steps and the result, and reflecting on the text and the solution process. Since solving the problem should motivate the introduction of equation and of a method for solving equations, students’ reflection about the formal representation of an equation and about the regulation of their own cognitive activities needed to write and solve an equation would be required to construct *metacognitive mathematical knowledge* about the new mathematical content.

Most of the learners solved the problem at home. In the class, Sabrina presents her solution (Figure 1):

x: Atlantik	$x + y + z = 320 \text{ Mio. km}^2$	$x = 82,5 \text{ Mio. km}^2$
y: Pazifik	$x + 2x + x - 10 \text{ Mio. km}^2$	$y = 165,0 \text{ Mio. km}^2$
z: Indischer Ozean	$4x - 10 \text{ Mio. km}^2 = 320 \text{ Mio. km}^2$	$z = 72,5 \text{ Mio. km}^2$
	$4x = 330 \text{ Mio. km}^2$	$\frac{320 \text{ Mio. km}^2}{4}$
	$330 : 4 = 82,5 \text{ Mio. km}^2$	

**Figure 1: Problem solution**

The transition from the equation in line 3 to this in line 4 raises many questions. A few students try to find out why one is allowed to change the equation in line 3 to the equation in line 4 (for reasons of space, the utterances are presented here in a shortened and more precise version):

Johana: I do not understand how you get from line three to line four.

Sabrina: Here, I did not know what to do, and then I asked my mother and she simply said, if you have to subtract something from  $x$  or from the variables, then you add that here to the result of it to be able then to continue the calculation.

Jonas: (...)  $4 \cdot x - 10$  million that is equal to 320 million. And then four times  $x$  without minus 10 million, it is clear that there are then 10 million more, because then you do not make the subtraction. That's why it's 330 million. (...)

Anna: (...) we want to have  $x$  on the left side alone. (...) and then you can only get the minus 10 million..., if you want to get rid of it, you just have to put 10 million on both sides. So on the left you have then  $4x$  minus 10 million plus 10 million. One

can then... yes you can take this away. Then there is only  $4x$ , and on the other side 320 million plus 10 million. (...)

### An analysis and assessment of metacognitive activities

Johana **reflects** (R6b) on her understanding of the solution, whereas Jonas and Anna **reflect** (R4) why one is allowed to change the equation in line 3 to the equation in line 4. (The meaning of codes R6b and R4 is explained in the category system linked in footnote 1.). Jonas analyzes the effect of the subtraction by 10 million on the value of  $4x$  and describes a relation between  $4x-10$  and  $4x$ . He uses this relation to find the value of  $4x$  if it is known that  $4x-10$  equals 320 million. Anna describes a clear goal of changing the equation (“we want to have  $x$  on the left side alone”) and suggests an arithmetic operation to change the term on the left side, but she does not explain why the terms on both sides of the equation have to be changed and can be changed as suggested by her.

The teacher arranges the class discussion in such a way that the students discuss their solutions without his guidance. This situation encourages the learners to take the responsibility for *solving the task* and to regulate their own cognition, thus to practice metacognitive activities such as planning, controlling and reflection. The students make use of this opportunity. They seem to be willing to plan, control and reflect their mathematical activities. In the sense of the *first guiding question*, this scene shows a high quality of metacognitive activities (answering category 4). High quality means that many metacognitive activities can be observed in students’ utterances and that these activities indicate students’ efforts to understand the solution.

The class discussion is led by a small group of students, who practice their metacognitive activities in an elaborated way by giving justifications related to mathematics and to their own understanding. They elaborated on the solution steps presented by Sabrina and on their own understanding of these steps. In the sense of the *second guiding question*, the lesson seems to indicate a high quality of metacognitive activities with justifications (answering category 4 to guiding question 2), meaning that giving elaborate metacognitive comments on the mathematical activities seems to be a desired, well established rule of the classroom culture in the class. But on the other hand, following this rule does not mean that the global class argumentation is coherent and focused on a precise elaboration of students’ understanding of the mathematical content. Consequently, this indicates a low quality of metacognitive activities with justifications (answering category 2 instead of 4 must be chosen).

Can this kind of metacognitive activities support students’ understanding of the new mathematical concept? Can it help to construct or deepen students’ meta-mathematical knowledge or to foster their meta-mathematical skills related to the mathematical content of the lesson? The three solution ideas as described by Sabrina, Jonas and Anna in the transcript differ significantly from each other. Unfortunately, the teacher makes no effort to elaborate on these approaches and to initiate co-constructive processes with regard to the meaning and adequacy of the new formal representation and of transforming it to find a solution. In the whole class discussion there are no activities indicating that the students reflect on each other ideas in order to understand how they differ from their own ideas, and whether all of them are correct and based on a valid mathematical argumentation. *Only very few students* try to explain the meaning of the equation and seem to have an idea of how to justify the transformations of the equation (answer 2 to guiding question 3). But since their ideas are not

elaborated and related to each other, the process of solving the equation is not effectively used to co-construct metacognitive mathematical knowledge about equations, and to make this knowledge well comprehensible for *all* students. Thus, despite lots of students' metacognitive activities, there are no visible effects concerning the construction and acquisition of metacognitive mathematical knowledge or fostering mathematical skills at the level of the whole class discussion. In the sense of the *third guiding question*, the metacognitiv-discursive quality of this lesson must be assessed as low (answering category 1 to guiding question 3), meaning that the extent to which metacognitive activities are used to foster students' understanding is not satisfying.

## Discussion

Training programs for fostering students' metacognition in learning mathematics concentrate on problem solving. But it seems hardly possible to acquire adequate metacognitive knowledge for solving problems – or even more general speaking, for a self-regulated use of mathematics in order to achieve a particular goal – without being engaged in metacognitive processes when constructing substantial mathematics-specific knowledge, such as knowledge about relevant concepts, methods, and strategies for thinking and reasoning (cf. Veenman et al., 2006). The lesson described in this paper shows that engaging students (in this particular class) in such metacognitive processes is not in the teacher's focus when solving a mathematical problem designed to introduce a new mathematical concept (equation). The teacher supports students' metacognition in the sense that he encourages them to plan, control and evaluate the solution among themselves. But he neither supports students' reflection on the new mathematical concept used in this process nor tries to explain or relate to each other the different conceptions described by the students to explain one step in solving an equation.

This is an alarming feature of the instructional quality of mathematics lessons. Mathematics teachers are expected to foster students' metacognition in order to deepen their understanding of mathematics and to enhance their skills in regulating their own cognition when using mathematics in different contexts. This alarming feature shows how promotion of metacognition in regular mathematics lessons is reduced to engaging the students in self-regulated processes of solving mathematical problems and tasks without taking care on the discursive quality of their mathematical discussion, and on their efforts in elaborating mathematical concepts and methods.

The rating system used to analyze the lesson can also be used to describe the need for a further improvement of instructional quality with regard to fostering students' metacognition. The high assessments given to the lesson with regard to the first and second guiding questions indicate that the students are able to execute metacognitive activities and willing to justify their answers and conceptions related to solving a linear equation. Unfortunately, the teacher does not use this potential to change the class discussion to a *discourse about the new mathematical concept*. In different words, the teacher does not make any efforts to shift the focus of the discussion from discussing the local steps of solving the given problem to a coherent discussion about the new mathematical representation (a formal representation of an equation) worked out in the process of solving this problem. This is, regrettably, the case in all four lessons videotaped in this class. This observation let us assume that improving the instructional quality with regard to students' metacognition requires changes in the discursive quality of the class discussion.

But this means more than just changing some social rules of discussion or increasing the number of students involved in the discussion. It rather means that the teacher and the students have to precisely control what the classmates say, explain differences between various conceptions and reasoning strategies mentioned in the class, and use this reflection to regulate their own understanding. It seems hardly possible to achieve this change without a close cooperation between teachers and researchers, and without engaging teachers in reflection on their practice.

The one lesson described in this paper does not allow us to generalize our assessment to all lessons of the particular teacher in this particular class. But, since the assessments given to all four lessons videotaped in this class are quite stable between lessons, it can be assumed that the problem described here is a general problem in this class. A transcript from the lesson following this one discussed in this paper is published in Nowińska (2016b). It shows that the students reflect on the sense of applying equivalence transformations to solve linear equations, and on their own difficulties in understanding the solution process. The teacher does not use these metacognitive activities to elaborate on the mathematical content and on students' understanding of it. He even seems to ignore students' reflections and justifications concerning their difficulties in understanding the mathematical content.

# Teachers' probing questions in mathematical classrooms connected to their practice of encouraging students to explain their thinking

Anna Östman

Mälardalen University, School of Education, Culture and Communication, Västerås, Sweden;

[anna.ostman@mdh.se](mailto:anna.ostman@mdh.se)

*Keywords: probing questions, teachers' practice, talk moves, elementary school.*

## Introduction

Asking questions is a common used teaching activity in mathematical classrooms and by arguing that there is a relationship between teaching and learning (Smith & Stein, 2011), the conclusion is that questions play an important role in teachers' practice in the mathematical classroom (Boaler & Brodie, 2004). Boaler and Brodie (2004) studied teachers' questions to find the nuances and differences of teachers' questions in mathematical classrooms. They found nine different types of questions (e.g. recall questions, questions supporting students in developing mathematical knowledge, questions which explore meanings and relationships, probing questions to get students to explain their thinking and questions generating discussions). The probing questions are considered critical in encouraging students to explain, clarify and reason. Connected to the probing questions, talk moves are considered useful for teachers in having a fruitful discussion with students (Smith & Stein, 2011; Kazemi & Hintz, 2014). The talk moves that can be seen in mathematical classrooms are for example revoicing, repeating and wait time (Kazemi & Hintz, 2014). Asking questions seems to be a teaching activity that teachers do not plan ahead of the lesson even though teachers make explicit that questions are important in the teaching (Boaler & Brodie, 2004). Asking probing questions also make students aware of their own responses and make students answer in the way they think the teacher expects an answer (Smith & Stein, 2011). Therefore, in this study I have chosen to focus on the specific questions where teachers are probing students to make their thinking explicit, e.g. "How did you think?", "How did you get your answer?"

The aim of the study is to categorize the different types of responses teachers give to students when students have answered teachers' probing questions. The prospective results will be analysed with the attempt to present different types of interaction patterns emerging from data, which are connected to teachers' responses and teachers' talk moves when students have made their thinking available and explicit through oral explanations. The results will be presented both qualitatively and quantitatively.

## Theoretical framework and methodology

The data in this study consists of videotaped mathematics lessons from 16 teachers, one lesson from each teacher, with six to nine years old students. In the data analysis, all episodes where teachers ask probing questions (Boaler & Brodie, 2004) were first identified together with the lesson phase in which each probing question appeared. In these episodes teachers' talk moves (Kazemi & Hintz, 2014) were used to find categories of different interaction patterns among teachers' responses. The interaction patterns are grown from the data and the patterns are used to explore the different ways teachers follow up students' answers after the probing question.

## Findings

Preliminary findings from the 16 teachers indicate that probing questions are used in all phases of the mathematical lessons and that students' responses to the probing questions vary between different teachers. The probing questions are most common during the lesson phase whole class discussion and student work. In the preliminary results, I have found that teachers use revoicing in 50% of the interactions following probing questions. Revoicing seems to help students extend their thinking and the results show that when a student's first answer is short without an explicit thought and teachers follow up with revoicing, students often express a developed thought (see Example 1). In contrast, when a student first answers with an explicitly developed thought and the teacher uses the talk move revoicing the next answer from the student is often short (see Example 2).

Example 1: Short student answer and teacher revoicing – students express a developed thought

Teacher: Tell me, how do you think?

Student: I counted

Teacher: You counted

Student: I counted; first, I counted those [showing cards with number 6, 1] and then those [showing cards with numbers 3, 4, 2]

Example 2: Developed student answer and teacher revoicing - students stop deepening their answer

Teacher: Please, explain your pattern, how do you think?

Student: The pattern starts over here [pointing to the pearls] and we were thinking small large small large

Teacher: You did think small large small large

Student: Yes

The preliminary results also show that teachers who regularly use the talk move wait time have students answering the probing question with developed thoughts. However, the talk move wait time is not commonly used by the teachers in this study.

## Linking the micro and macro context: A sociocultural perspective

Maria Pericleous

Cyprus Ministry of Education and Culture, Cyprus; [mariapericleous19@gmail.com](mailto:mariapericleous19@gmail.com)

*In this paper, I present and discuss findings from a research study the aim of which is to investigate the activity of proving as constituted in a Cypriot classroom for 12 year old students. Through Cultural-Historical Activity Theory (CHAT), the influence of research literature, curriculum prescriptions, the students and critically the teacher are documented. The evolution of objects, in particular the aims of the teacher, and other components in the activity systems are traced. Perceiving the mathematics classroom as a nested activity within educational context levels, this paper considers the role of the broader social context in which this classroom is situated.*

*Keywords: CHAT, contradictions, proving, mathematics*

### Theoretical framework

It is now acknowledged that proof and proving should become part of students' experiences throughout their schooling (Hanna, 2000; Stylianides, 2007; Yackel & Hanna, 2003). It is also argued that argumentation, explanation and justification provide a foundation for further work on developing deductive reasoning and the transition to a more formal mathematical study in which proof and proving are central (Yackel & Hanna, 2003). But what is meant by proof and proving? Mathematical argumentation is a discursive activity based on reasoning that supports or disproves an assertion and includes the exploration process, the formulation of hypotheses and conjectures, explaining and justifying the steps towards the outcome and the proof of the statement. Thus, proof is at the core of mathematical argumentation, as a justification, an explanation and a valid argument. Research has responded to the need to conceptualize proof and proving in such a way that it can be applied not only to older students but also to those in elementary school (Stylianides, 2007). The challenge remains however to understand how proof and proving is shaped by the practices in the mathematics classroom. This is in accordance with Herbst and Balacheff (2009), who argue that the focus should not only be on proof as the culminating stage of mathematical activity, but also on the proving process and how this is shaped by the classroom environment. Thus, in understanding how proving is constituted in the classroom, a wider network of ideas is required as these ideas no doubt have an impact on how proof in the narrow sense is constituted.

To address this issue, I refer to pre-proving, that aspect of mathematical reasoning that might nurture proving. What are the roots of proving? The purpose of this study is to investigate proof and proving in the naturalistic setting of the classroom and the way the structuring resources of the classroom's setting shape this process. Instances of students proving statements have been identified in this classroom community but instances where the argument was not in the conceptual reach of the classroom have also been identified. However, this study also points to those aspects of reasoning that appear to have the qualities of proving, even though they may not be proving in themselves. That is, analyses of video-recorded whole class discussions show how processes of explaining and exploring are key sub-systems within the central activity of proving as they provide a key pathway, which often includes defining. Thus, pre-proving refers to those elements that direct mathematical

reasoning towards the ultimate goal of formal proving, namely exploring, explaining, justifying and defining. This study considers mathematical explanation an act of communication, the purpose of which is to clarify aspects of one's mathematical thinking that might not be apparent to others (Yackel & Cobb, 1996). Justification is "the discourse of an individual who aims to establish for somebody else the validity of a statement" (Balacheff, 1988, p. 2). There is insufficient scope in this short paper to consider in detail these various levels and so this specific study focuses on the way the activity of the mathematics classroom (micro context) is influenced and dependent upon wider educational context (macro context). This is in accordance with Balacheff (2009) who argues that among the important pieces in trying to understand the nature and role of proof in a mathematics class is describing the general usage of the word proof in these contexts and the demands this usage imposes in the classroom.

### **CHAT based underpinnings**

As this study is exploring the various forces that impact on the activity of proving, Cultural Historical Activity Theory (CHAT) is being employed as a descriptive and analytical tool alongside collaborative task design (a means of gaining access to the teacher's objectives), to capture the interaction of different levels, such as the actions of teachers, students and the wider field as evidenced in curricula and research documentation. The analysis and discussion in this paper draws upon the following CHAT perspectives: (i) the object of the activity and (ii) the notion of contradictions. Initially, the unit of analysis in CHAT is an activity, a "coherent, stable, relatively long-term endeavor directed to an articulated or identifiable goal or object" (Rochelle, 1998, p. 84). Engeström (1987) introduced the activity system, a general model of human activity that embodies the idea that both individual and social levels interlink at the same time. Jaworski and Potari (2009) argue that the activity system is a micro context within broader macro context levels. Thus, the activity of a mathematics classroom is influenced and dependent upon the structure and organization of the school and the Ministry of Education as wider educational contexts. The object of a collective activity is something that is constantly in transition and under construction. It has both a material entity and is socially constructed and its formation and transformation depends on the motivation and actions of the subject indicating that it proves challenging to define it.

Among the basic principles of CHAT is the notion of contradictions. Contradictions are imbalances, ruptures and problems that occur within and between components of the activity system, between different developmental phases of a single activity, or between different activities. These systemic tensions lead to four levels of contradictions (Engeström, 1987). Contradictions are important because they may lead to transformations and expansions of the system and thus become tools for supporting motivation and learning. That is, contradictions do not serve as points of failure or problems that need to be fixed. "Rather than ending points, contradictions are starting places" (Foot, 2014, p.337). This paper focuses on tertiary contradictions that appear between the object and the culturally advanced form of the central activity, a clash between the micro and macro level. Compared with other studies investigating tertiary contradictions, this study takes a rather different approach in discussing the tertiary contradiction that has emerged within this particular activity system. That is, the collaborative task approach assisted in exposing the teacher's object. Even though introducing a new mediational tool resulted in new actions being brought into the activity, this did not affect the object of proving

as a cultural historical activity system. Thus, when elaborating on tertiary contradictions, this discussion focuses on a possible clash between the micro and macro level of this activity system, due to a differentiated object.

### **Data collection and analysis**

This study was conducted in a Year 6 classroom in a public primary school in Cyprus. This mainstream school is considered to be a dynamic school; it actively encourages teachers and students in engaging at a deeper level with the educational experience. Apart from the researcher, the participants were the teacher, a Deputy Principal at the school who endorses the integration of technology in teaching mathematics, and voluntarily agreed to take part in the research, and 22 students (11–12 years old) of mixed abilities. Even though using computers was part of the classroom's routine, the students were not familiar with Dynamic Geometry Environments (DGEs). The data collection process was undertaken in three phases. Phase I aimed at identifying the system level and the teacher level, by employing documentary analysis and semi-structured interview. The system level, which remained the same throughout the study, in the broader sense, refers to the policy statements, curriculum, textbooks, research about proof and proving. The official documentation was analyzed so as to collect information concerning the role of proving in primary education, the objectives for teaching and learning geometry, the geometrical tasks illustrated as important for developing geometric thinking and understanding, the approaches the ICT offers in facilitating the teaching and learning of school geometry. The teacher level refers to the teacher's attitudes and perceptions concerning the role of proof in the curriculum and in the mathematics classroom, compared with what the teacher actually does in the everyday mathematics classroom. The interview with the teacher aimed at exploring the teacher's beliefs and views regarding the nature of mathematics, the nature of teaching mathematics and the nature of learning mathematics. The main research focus of Phase II was to map the current situation of the classroom. The data collection process included video data from the classroom observations and field notes from the informal discussions with the teacher. My involvement in the classroom could be described as moderate participation. In Phase III, the researcher collaborated with the teacher to design DGE-based tasks as a means to gain access to the teacher's objectives. The tasks were the research vehicle, the window for generating data rather than any kind of curriculum intervention. The research instruments were classroom observation, informal discussions with the teacher and the DGE-based tasks. In Phase III, I had an active role in the classroom. My involvement was related with answering questions related with the tools the DGE provided, which the students had to use in order to explore the tasks, and asking probes. Each phase of data collection was distinct as it corresponded to specific purposes. At the same time, themes of interest, emerging from the ongoing analysis of each phase, also informed the design, implementation and analysis of the subsequent phases. The content of the curriculum covered during the classroom observations was the area of triangles, and the circumference and the area of circle.

The overall process of analysis of the collected data was one of progressive focusing. According to Stake (1981, p.1), progressive focusing is “accomplished in multiple stages: first observation of the site, then further inquiry, beginning to focus on relevant issues, and then seeking to explain”. The systematization of the classroom data led to the evolution of two broad activities: (i) the activity of

exploration including the exploration of mathematical situations, exploration for supporting mathematical connections (between the content of mathematics, with which the students are engaged, with parts of mathematics that they would be taught in secondary school or that were taught either recently or in the past, as well as between classes of problems) and exploration of the DGE and (ii) the activity of explanation which focuses on clarifying aspects of one's mathematical thinking to others, and sometimes justifying for them the validity of a statement. These activities were then interpreted through the lens of CHAT, by generating the activity systems of both exploration and explanation. Analysis of the classroom data revealed that the activity of explanation unfolded and expanded around mathematical definitions and defining as activity. What is the connection between definitions and explanation? Definitions are conventions that require no explanation. However, the teacher wanted reference to the attributes that involved properties. That is, the move from a definition involving only perception to a definition that involved properties needed explaining. The situation of the classroom regarding proving activity was further scrutinized by contrasting the outcome of the activity with the social context in which it emerged. Instances of both congruence and diversion existed between the micro and macro level.

### **What is the object of developing proving in the classroom?**

It has been illustrated that pre-proving activity is closely connected with exploration and explanation. Correspondingly, the object of developing proving in the classroom is related with these notions. The object has multiple manifestations for the participants engaged in the activity. Exploration is related with the pre-proving activity when information is revealed through the immediate feedback students get from the manipulation of objects. For instance, on a blank DGE window, the teacher asked the students to find the area of triangles. The students had the opportunity to explore this mathematical situation on a DGE and decide for themselves which tools should be utilized that would assist them in finding the area of the triangles.

Additionally, explanation entails a process where mathematical definitions are being formulated. The students cannot rely only on perception as a definition in this particular classroom is considered more what a concept really is rather than a description of how a concept is used. For instance, the question "What is the altitude in a triangle?" directed the classroom towards formulating the definition of the altitude in a triangle. Explanation also entails a process where the sociomathematical norms are being negotiated. For instance, the first lesson where the students were introduced to the area of mathematics related with circle, was initiated by a question.

Teacher: What is circle?

Student: It is a shape that does not have sides or angles.

Teacher: I draw a circle according to this definition. (*The teacher draws a non-regular shape with curved lines.*)

Student: This is not a circle.

Teacher: We said that in mathematics our definitions must be accurate.

Students are expected to use precise mathematical language when communicating their ideas as well as when writing coherent geometrical explanations, clarifying aspects of their mathematical thinking

to others, as well as justifying for them the validity of a statement. For instance, following the classroom discussion on defining circle, the teacher asked students to determine whether several shapes illustrated on the whiteboard were circles.

Teacher: Is this a circle?

Student: No.

Teacher: I do not accept your answer. Why?

Student: There ... on the right ... the other shapes are not circles because their center does not have the same distance from their circumference.

As proofs begin with an accepted set of definitions and axioms, it can be argued that ultimately all proofs depend on the underlying definitions and the earlier results derived from these definitions. Thus, understanding and explaining these definitions is a prerequisite when approaching a proof. For instance, after the class reached a conclusion regarding the mathematical formula for the circumference of circle and made hypotheses concerning the mathematical formula for the area of circle, the teacher gave each pair a circle divided in either 8 or 10 pizza pieces, commenting that they could use the pizza slices to explore the area of circle.

Student: We finished. Can we tell you? Radius times half the circumference. It's a rectangle thus the length is the radius and the width is half the circumference because it's half.

In addition, making forward connections provides more information and knowledge about the axiomatic system in which the classroom community is working. Forward connections also strengthen the formulated definitions. For instance, after the class explored the number of altitudes in a triangle, the teacher made the following comment:

Teacher: This is what I was trying to achieve. All the altitudes pass ... this is not part of our curriculum but part of the mathematics curriculum of secondary school, but it's good for you to know because it helps you. A triangle has three altitudes. From each vertex I can construct an altitude to the opposite side.

Consideration of the aforementioned manifestations of the object leads to the conclusion that the object of the central system of pre-proving activity is related with exploration that leads to explaining and justifying for a specific part of the mathematics curriculum. Nevertheless, the object is simultaneously hindered due to the dichotomies, tensions and conflicts. At a first glance, this object seems to be clear and distinct. However, this object is multifaceted. The teacher on one hand understands the importance of providing enjoyable exploring opportunities that keep students' motivation and interest to engage with the problem. As a result, the teacher provides opportunities that can be approached by the students in their own way. On the other hand, students, through the exploration of these opportunities are expected to reach those conclusions regarding triangles and circles as pre-determined by the teacher. The two poles of the object lead to a constant struggle in the teacher's everyday practice. The teacher, due to this multifaceted object, is faced with the play paradox (Hoyle & Noss, 1992) as well as the planning paradox (Ainley, Pratt, & Hansen; 2006). As a result, teacher would at times decide to close down an exploration opportunity. For instance, after

exploring the circumference and area of circle, the teacher, asked the students to find a relationship that related the circumference and the area of the circle. Soon after that she asked them to prove mathematically that the ratio area/circumference of a circle is  $r/2$ . In a similar way, the object of the activity of explaining as part of pre-proving is multifaceted. The object for the teacher is twofold: explaining mathematical procedures and explaining related with 'proving'. On one hand, the teacher's object is related with engaging students in formulating definitions (of concepts and formulas) in the same way that mathematicians do. In order for these definitions to become operable for the students, they need to focus on the properties required. Thus, this process includes a continuous interplay between the concept image and the concept definition, promoting the characteristics of definitions and making the distinction between 'ordinary' and mathematical definitions. Even though the above facilitate the justification of statements, a tension within the object arises. That is, ensuring that the classroom engages in the construction of stipulated definitions and that these definitions are not just descriptive for the students seems to be competing with moving to justification based on these definitions. Furthermore, even though the teacher is embracing this object, she is simultaneously faced with the play and planning paradoxes, influencing the way she intervenes while this process of explaining and justifying develops in the classroom. If the students' argumentation leads to a discussion that diverts from the teacher's object, the teacher may decide not to take advantage the opportunity that arises, for further engaging students in explaining and justifying.

### **Identifying points of contradiction**

Tertiary contradictions appear between the object of activity in a central activity and the 'culturally more advanced' activities. Analysis of the micro activity system as a classroom which is nested within the system level such as the institutional level in which the school is part of, as well as the cultural-historical level which is involved with the available research literature results into identification of a tertiary contradiction due to a differentiated object. The two poles of the object of the central activity of the classroom related with pre-proving activity will unavoidably clash with the object of pre-proving activity as identified in the system level. Initially, a contradiction between the classroom level and the institutional level resides in the fact that there is no clear identification of an object related to proving. That is, analysis of the official documentation indicates a general object of mathematical activity that is not necessarily in accordance with the object of the teacher related to pre-proving activity. To be more precise, the information collected from the official documentation points to low level of expectation with regards to exploration and investigation in problem solving in Year 6. Analysis of the report of the official documentation shows that proof and proving is not being acknowledged as a key criterion, nor mentioned in the mathematics curriculum. Furthermore, explaining and justifying points to an explanation being given by providing the mathematical operations used to find the answer and the justification being provided by using the definition. Adding to the above, there is no formal requirement regarding definitions. Definitions as approached by the official documentation are descriptive and extracted. This is not in accordance with the teacher's practice where definitions play a vital role. One may argue that a consideration of the educational objectives, as pre-determined by the mathematics curriculum, leads to the conclusion that the outcome of the teacher's practice is the one intended by these objectives. However, in order for this to be achieved, the pre-proving activity is narrowed down. Thus, for instance, providing answers based on

definitions and properties of shapes clashes with providing explanations based on the conceptual aspects of the definitions and the shapes. In a similar way, this tertiary contradiction concerns the cultural-historical level as well. Even though at a first glance the teacher's objects seem to be in line with the established research literature related with proving, the dilemmas the teacher needs to confront, as well as the ambiguity of the notion of proving existing at the institutional level, clash with the cultural-historical level.

## **Discussion and conclusions**

A consideration of the above rationally points to the inference that the advanced form of the central activity object is not yet the dominant form of the activity. Thus, it can be argued that a first step towards a unification of these activities should be the resolution of the tension that exists within the macro system. Would providing a mathematics curriculum, which defines its object concerning proving and defining activity by incorporating crucial elements from the research literature, lead to a desired outcome?

The discussion regarding tertiary contradictions reveals the value of this concept in understanding systems of activity. By identifying the manifestation of contradictions through the materialized tensions, a holistic view of the phenomenon under investigation emerges. It is accepted that not all emergent contradictions can be resolved simultaneously. While a resolution exists for some contradictions, others are suppressed. That is, the contradiction on the teacher's object is continually present, surfaces in the teacher's everyday practice in various forms and is foundational to the other levels of contradiction. However, since this contradiction remains, the discussion should be centered on the means that the teacher can turn to for a possible and fruitful resolution of the contradictions that emerge in the other levels. Elaboration of the emergent tertiary contradictions leads to asking whether a possible balance between the macro level would be an aid in the resolution of the tensions manifested as contradictions in the micro level. Due to the way the aforementioned forces impact on the classroom activity, providing a straightforward answer is not an easy task. Undoubtedly, as it has been exemplified, proof and proving might be encouraged in all school levels. This indicates that exemplification of the role of proof, explanation, exploration and definitions might be included in the mathematics curriculum and the relevant curriculum material. Perhaps, a clear connection between the aforementioned would relieve, to an extent, the teacher from paradoxes. That is, knowing that the above aspects of mathematical reasoning might not be necessarily competing with each other and may be the way for a resolution of the play and planning paradoxes, as the purpose and utility underlining the task design would not clash with the object of the central activity system (Ainley et al., 2006).

Adding to the above, the fact that the official documentation is implemented in the classroom by the teacher points once again to the crucial role of the teacher. Specifically, the above findings further highlight the role of the teacher's knowledge about proof in mathematics teaching. Keeping in mind the findings of this study related with definition construction as part of pre-proving activity, it is important to consider essentially that the types, the characteristics and functions of mathematical definitions should be taken into account when understanding and describing the mathematical knowledge for teaching when engaging students in proving activity. Would this element of

knowledge enable mathematics teaching to support desirable student learning outcomes in the domain of proof and in mathematics more broadly?

*In this paper we investigate how a group of six mathematics teachers in Greece deals with the need to balance work on mathematically demanding tasks and differentiation in lesson planning and enactment. Videotaped lessons and pre and post reflection interviews were analysed with a specific focus on whole class discussion. The findings show certain teaching practices that appear to promote both mathematical challenge and differentiation and emerging patterns of actions that make the challenge accessible to students.*

*Keywords: Mathematically challenging tasks, whole class discussion, differentiation.*

### Introduction

Research on challenging tasks and differentiation has contributed to deepen our understanding of teaching. The former explored ways to engage students in rich mathematical activity through tasks advancing their thinking and reasoning (Stein, Smith, Henningsen, & Silver, 2000). The latter pertains to research in differentiating teaching so as to engage all the students in mathematically productive learning experiences (Sullivan, Mousley, & Zevenbergen, 2006). Bridging challenging tasks and differentiation constitutes an area that is not explored at the research level. However, it seems to be at the core of everyday teaching since working with rich mathematical tasks requires taking into account explicitly how all students could be engaged with them both at the level of lesson planning and enactment. Whole class discussion can be seen as a terrain providing fertile opportunities to study in what ways teachers might work at the intersection of mathematical challenge and differentiation. During whole class sessions a teacher faces the need to preserve a mathematically productive discussion and at the same time to respond to diverse students' abilities, learning styles and paces (Sullivan, Mousley & Zevenbergen, 2004). The present study aims to address this issue by focusing on mathematics teachers' attempts to work at the intersection of mathematical challenge and differentiation while designing tasks and orchestrating whole class discussions in their classrooms. The research question is: "How do teachers attempt to balance mathematical challenge and differentiation in whole class settings?"

### Theoretical framework

Challenging tasks are those that require students to: process multiple pieces of information with an expectation that they make connections between those pieces and see concepts in new ways; explain their strategies and justify their thinking to the teacher and other students; engage with important mathematical ideas; and extend their knowledge and thinking in new ways (Stein et al., 2000). Working with challenging tasks seems to be rather demanding for the teachers at the level of design and enactment. Lesson planning involves design of tasks that support a learning trajectory and extend students' thinking (Sullivan et al., 2006). Handling the enactment of challenging tasks during whole

class sessions requires specific actions by the teacher to support students' mathematical discourse. These involve talk moves such as revoicing, repeating, reasoning and adding on (Chapin, O'Connor, & Anderson, 2009) as well as key practices such as anticipating, monitoring, selecting, sequencing, and making connections between student responses (Stein et al., 2008). Stein et al. (2000) proposed three paths to describe how teachers handle the demands of challenging tasks in their lessons: lowering, maintaining, or increasing the challenge.

Differentiation is a process of aligning learning targets, tasks, activities, resources to individual learners' needs, styles and paces (Beltramo, 2017). In supporting teachers in dealing with differentiation issues at the level of lesson planning existing literature suggests focusing on content, process, and product (Tomlinson, 2014) or providing enabling prompts to support students experiencing difficulty and posing extension tasks for students who finish the tasks quickly (Sullivan et al., 2006). Researchers suggest that the goal of addressing differences between students in lesson enactment can be effectively carried out by building of "a sense of communal experience" (ibid, p. 118) where all students benefit from participation on common discussions.

Whole class discussion constitutes a phase of the lesson enactment where mathematical challenge and differentiation can be at interplay providing opportunities for further study. According to Dooley (2009), whole class discussion is both emergent because the outcome cannot be predicted in advance and collaborative because it is the outcome of the collective activity between the teacher and the students. Focusing on the tensions involved in teachers' attempts to build on students' ideas for mathematically productive class discussion, Sherin (2002) highlights the need to maintain the student-centered process of mathematical discourse and to direct the content of the mathematical outcomes. In the present study our focus is on teachers' actions to balance mathematical challenge and differentiation in this rather complex part of the lesson.

## Methodology

EDUCATE is a professional development (PD) European project aiming to support teachers to engage all their students in challenging tasks. To achieve this goal, four partners/university teams from different countries collaborate to develop teacher education activities and materials. The current study took place in the introductory phase of the project where the partners' aim was to explore teachers' needs and challenges in relation to working with challenging mathematical tasks and differentiation without being engaged in any teacher education/PD activity. In this paper, we use the data collected in Greece and it involves the teaching of six practicing secondary school mathematics teachers (Adonis, Eugenia, Markos, Gianna, Kosmas, Takis, all pseudonyms) who participated in the study in a volunteering base. All of them were experienced, qualified teachers but without any PD professional development experience related to address together mathematical challenge and differentiation. Their years of experience ranged from 10–25 years at the time of the study. Three of them worked in experimental schools and the rest of them in typical public schools. Also, three of them were teaching in lower secondary and the rest in upper secondary school classes. One of them had a doctoral degree in mathematics education (Kosmas), three held a master's degree in mathematics education (Adonis, Markos, Gianna) and one held a master's degree in pure mathematics (Takis). All teachers had collaboration with the university team either during their studies or through

their participation in other research projects. Participants were informed about the project rationale/aims and they were asked to design challenging tasks and enact them as part of their everyday teaching with the goal to engage all their students. They were also informed that we were interested in the challenges and difficulties encountered by them when implementing these tasks without further details on how to proceed with this goal.

Data collection included: video-recording of two lessons for each teacher (12 video-recordings in total); pre- and post-lesson reflections/interviews (12 in total); teachers' designs for their lessons (e.g., worksheets, digital resources) and students' work. The recorded lessons lasted one teaching hour (45-50 minutes) and were carried out between December 2017 and January 2018. Under a grounded theory approach (Charmaz, 2006), we analysed lesson planning and enactment with a particular focus on whole class sessions considering the setting up of the task and the discussion of students' solutions. Balance of mathematical challenge and differentiation in teachers' designs was addressed by triangulating the analysis of teachers' lesson plans, teaching materials and pre-lesson reflections focusing on (a) the designed tasks, (b) the used resources and (c) the decisions related to classroom implementation (i.e. group work, role of teacher, classroom norms). In the videotaped lessons, we identified episodes indicating a balance between mathematical challenge and differentiation. Mathematical challenge was originated either by the task itself, a student's query or the teacher's extending prompt or question. Differentiation was expressed by the teacher's attempts to make the challenge accessible to all students. Shifts in the students' engagement with the challenge in the episodes were identified (by us) mainly by interpreting students' progressive participation in the mathematical discourse.

## Results

In the first part of this section we analyse teachers' designs. In the second part we present selected episodes from classroom observations indicating a balance between mathematical challenge and differentiation. Our focus is on the teaching actions and their interplay that indicate a process of making the challenge accessible to all students and not on cases where this was not evident.

### How mathematical challenge and differentiation were balanced in lesson planning

Each lesson was based on a sequence of tasks and activities to be undertaken by students so as to support each teacher's learning goals. Most tasks (21 out of 25) can be characterized as challenging offering opportunities to students to: model an everyday situation through arithmetic, algebraic and geometrical relations (Markos – 7<sup>th</sup> grade, Adonis – 7<sup>th</sup> grade, Gianna – 10<sup>th</sup> grade, Eugenia – 8<sup>th</sup> grade); link algebraic and geometrical representations (Kosmas, 10<sup>th</sup> grade); or conjecture and prove a geometrical property (Kosmas – 10<sup>th</sup> grade, Takis – 10<sup>th</sup> grade).

Analysis of teachers' pre-lesson interviews allowed us to identify their goals and actions for proactively planning the level of mathematical challenge and support provided to meet different students' needs. As regards the mathematical challenge, the teachers attempted to integrate it in their didactical designs and make it accessible to all students through the following planning actions: (a) *Designing tasks with multiple solutions and different entry points*. For example, Kosmas asked students to use both algebraic and geometrical ways to solve equations with absolute values. The teacher knew that there were students (e.g., Maria) who could easily handle the geometrical way

while they had difficulties in the algebraic. The teacher considered the use of the geometrical way as challenging as it required a deeper understanding of the meaning of absolute value. Offering different entries for the students was related to the process of exploration often in the context of open and/or modelling problems. For example, Eugenia designed a modelling task on estimating the height of the classroom as an application of the tangent trigonometric notion. (b) *Using different kinds of resources (e.g., manipulatives, digital applets, diagrams, typical and non-typical measuring instruments)* to facilitate the making of connections between different representations. Markos, for instance, used digital tools (*Algebra Arrows* applet) to facilitate students' focus on the structure of arithmetic and algebraic expressions. Eugenia offered a hand-made protractor (a measuring instrument originated in the ancient Greek mathematics) and she commented about the critical role of this tool in mediating the conceptualization of the notion of tangent ratio. (c) *Creating an inclusive and mathematically challenging learning environment* by encouraging students to share their work in groups and in whole class discussions and avoiding evaluative comments. These actions were included in different ways in all teachers' didactical agendas. For example, Eugenia attributed emphasis to the roles and responsibilities she assigned to the students in each mixed ability group according to their mathematical backgrounds and interests.

### **How mathematical challenge and differentiation were balanced in lesson enactment**

The episodes that follow are chosen to indicate illustrative ways by which the teachers stimulated the mathematical challenge and attempted to balance it with differentiation in different phases of the lesson. Episode 1 is selected from the setting up of the task and the challenge is based on the teacher's strategy. Episodes 2 and 3 are taken from the discussion of students' solutions and the starting point was students' difficulties or unexpected responses. In parentheses (italics) we characterize teachers' actions and at the end of each episode we summarize the teachers' actions.

#### *Episode 1: Stimulating the key mathematical idea by exploring the validity of students' responses*

This episode took place in one of Kosma's lessons in Geometry (10th grade). The task given to the students was the following: "How many degrees is the sum of the three angles of a triangle? How can we be sure about the answer?" (In the worksheet, there is an oblique triangle drawn and a triangle with an obtuse angle). In this task the challenge concerned the students' engagement in appreciating the need for proof. In the episode, we see how Kosmas promotes the challenge and at the same time the way that he formulates the task to allow the engagement of all students.

The teacher asks the students: "Are we sure that the sum of the angles of a triangle is 180 degrees?" (*stimulating the challenge*). Although most of the students reply that they know it from previous grades, Alexis, one of the students having usually limited participation in the lesson, suggests to prove it by measuring. The teacher asks him "If you measure the angles do you think that you will find 180 degrees?" and he asks all students to draw triangles and measure their angles by the use of a protractor (*valuing students' ideas by addressing them to the whole class; encouraging empirical solutions*). Alexis finds 179 degrees and other students 178, 179, 180, 181. The teacher writes these responses on the board (*recording and discussing all students' answers*) and asks students: "How can we be sure? It seems that we cannot be sure by measuring" (*refuting the empirical solutions*). Through these actions the teacher seems to point out the key mathematical idea to the students by building on Alexis'

suggestion for an empirical measurement. He intentionally accepts Alexis' suggestion and invites all students to perform measurements in different triangles. Next, he records all students' answers on the board as a way to question the validity of the approach. In his pre- and post-lesson reflection the teacher mentioned that he targeted the empirical justification to be discussed: "The discussion was what I wanted as the responses varied. It also went well since most students were involved, also by working in groups felt less exposed to evaluation" (Kosmas' post-lesson reflection). In this episode, the teacher stimulates the mathematical challenge of the task, encourages students to explore an inappropriate idea coming from a student, summarizes their responses, provokes the refutation and reinforces the challenge.

*Episode 2: Using digital resources to address mathematical challenge and students' difficulties*

This episode took place in one of Markos' lessons (7<sup>th</sup> grade) about the structure and equivalence of arithmetic and algebraic expressions through their connection to a realistic situation. The task and the corresponding questions revolved around the idea of describing an everyday situation (Maria's account balance after shopping) with different ways through simple arithmetic expressions (initially) and algebraic ones with the use of one and more than one variables (subsequently). The problem situation is described as follows: "Maria has 500€ in her bank account. She bought meat that cost 10€ She also bought fish that cost 20€ She used her debit card and received a message from her bank on her mobile, informing her that her account balance is 470€". The challenging dimensions of the task were related to the use of a realistic situation as a context of reference in conjunction with a multi-representational applet (*Algebra Arrows*) to identify the structure of arithmetic and algebraic expressions. We note that the construction of expressions in the environment is concretized by connecting Input/Output fields (including numbers or variables) to operation fields through the use of arrows. The environment provides the final result of the calculation as well as its structure (that is represented through arrows and symbolically). The students – who were familiar with the use of the applet - were given a worksheet involving the questions and a printed representation of the work area of *Algebra Arrows*. They worked in groups for about 5 minutes on a specific question with paper and pencil on the worksheet. After each group work session, the teacher used the *Algebra Arrows* representations (provided through a projector) to discuss students' solutions/reflections in a whole class discussion.

The episode took place after students describing the account balance and their relation [the expressions were:  $500-10-20$  and  $500-(10+20)$ ]. The class discussion concerned the students' solution to the questions: "If it is not known the initial amount of Maria's money in her account, construct through the use of *Algebra Arrows* two different expressions to describe the amount of money left in the account. What is the relation between the two expressions?" During the preceding group work session the teacher knew that the group 1 students (4 girls) had written correctly two expressions using variable for describing the situation – i.e.  $x-(10+20)$  and  $x-10-20$  – but they faced difficulty to consider them as equal. The teacher invites the students to discuss about the solutions in a whole class session. Before constructing the two expressions with the applet, he asks the students what are these expressions (*stimulating all students to provide the solution*). One student answers: " $x-(10+20)$  and  $x-10-20$ ". Then Markos constructs the two expressions with the applet and asks students to provide the answer before this is projected (*using multiple and interconnected digital*

*representations to justify an answer*). Next, he comes back to the group 1's concern posing the question they discussed during autonomous work to the whole class showing the two fields in the applet: "Girls, I remember that earlier you were concerned if it is the same 'x' that appears here [in the expression  $x-(10+20)$ ] and the 'x' that appears there [in the expression  $x-10-20$ ]. This is a question for the whole class. I ask: Does this 'x' express the same thing?" (*posing an individual student difficulty to the whole class; stimulating all students to reflect on the provided representations*). One student (Nick) replies: "They are the same as they are connected with the same field – entitled Maria's Money: x - in the applet". The teacher indicates that both expressions are built by using the same field symbolized as 'x' (*revoicing the correct answer*): "Look the arrows starting from the cell containing Maria's initial amount of money. We speak about Maria's money in both expressions (*linking the digital representations to the realistic context*). In this episode, the teacher brings an individual student's difficulty in the whole class through the use of digital representations, stimulates all students to reflect on the provided representations, revoices a student's correct answer, strengthens the challenge by providing links to the realistic context.

### *Episode 3: Building on students' unexpected responses to extend the challenge for all students*

This episode took place in one of Adonis' lessons (7<sup>th</sup> grade) about the exploration of the binary number system in the context of a real problem with three questions. The task context is a flour mill in the 19<sup>th</sup> century. The owner (the miller) has only one weight of 1kg, one of 2kg, one of 4kg, one of 8kg and one of 16kg. He claims that he can weigh sacks of flour until 31kg using these weights. In the first two questions, the students are asked how the miller weighs (1) a sack of 18kg and (2) sacks of 1, 2, 3, ... 31 kg (table is given to be filled in). The third question is how many kilos were contained in a sack where the miller has written on it the number 1011. Before the episode, the teacher had explained how weigh scales were used in the 19<sup>th</sup> century. The students completed the first and the second question rather easily. The mathematical demand increased in the third question when the students had to identify how the binary system 'works'. The teacher draws a sack on the blackboard and besides he writes the number 1011 and asks: "What does the number 1011 mean?" (*stimulating the challenge*). Fenia provides the following answer: "The number 1011 means that the miller used 1 weight of 16kg, none of 8kg, 1 of 4 kg and 1 of 2kg". The teacher asks students if they agree with Fenia (*valuing students' ideas by addressing them to the whole class*). Students provide different wrong responses (e.g., "It means 1kg and 11gr", "It means the price, 10Euros and 11cents"). In the realm of the rich discussion where different opinions were expressed, Ian suggests: "Perhaps we have to start from the right. One weight of 1kg, 1 weigh of 2kg, none weight of 4kg and 1 weight of 8kg". This idea created uncertainty among the students, and it was also unexpected for the teacher ("I couldn't decide immediately how to handle it. I let the discussion to continue and I think that finally we reached a consensus", Adonis' post-lesson reflection). The teacher writes Fenia's and Ian's responses on the board to make them accessible to all students (*recording students' responses on the board*). Then he invites all students to compare these two solutions focusing on the place value of the digits (*stimulating the key mathematical idea*). He proposes to look at the tables they had filled on the distribution of weights from 1Kg to 31Kg in the previous question and asks students to find the place value of each digit (*linking the key mathematical idea to a previously answered question*). The teacher writes on the board upon each digit the values that the students provide (1, 2, 4, 8 from left to right).

The disagreement is still evident in the discussion and it is made explicit by one student who says: “We do not know if the miller represented the weights by writing the digits from left to right or vice versa”. Most of the students seem to consider it as a dilemma. The teacher invites – for first time - a high achiever (Tom) who raised his hand in all questions. Tom says: “The value of each digit depends on its place and the number system that the miller uses”. The teacher revoices Tom’s opinion emphasizing that the value of each digit depends on its place. There are students still providing wrong answers about the place value of the digits. The teacher writes on the board an integer (i.e. 1357) in the decimal number system and asks the students to find the place value of each digit (*simplifying the initial challenge through a familiar case*). A lot of students provide correct responses, but the teacher brings back the challenge: “Why do I have to accept it? How do we know what is the value of each digit?” (*bringing back the challenge*). The teacher addresses students who are reluctant to respond (*giving voice to silent students*). One of these students says: “We know it as a rule” and another one adds: “We have defined it. We have agreed to use it this way”. The discussion continues this way and more students participate. The teacher continues to bring as examples integers from the decimal number system (*simplifying the initial challenge*) and invites students to compare the two systems (*extending the challenge*). In this episode, the teacher brings a challenging issue by an individual student in the whole class, stimulates all students’ reflection, gives voice to silent students, makes links to familiar representations and extends the challenge by inviting students to make comparisons.

## Conclusions

In this study we focused on teachers’ attempts to balance mathematical challenge and differentiation. Mathematical challenge was targeted by all teachers through the design of mathematically demanding tasks and the use of different resources (e.g., realistic contexts, diagrams, concrete materials, digital representations) to engage students in exploring, connecting and reflecting. During lesson enactment the teachers’ approaches to stimulate the challenge involved building on students’ ideas (revoicing, rephrasing, reformulating) as well as scaffolding by simplifying (e.g., bringing a familiar case/situation) and extending in a dynamic way (e.g., comparing different approaches/solutions/representations). Valuing students’ contributions and addressing them to all students appears at the core of teachers’ orchestration of the whole class discussion. The teachers appear to use students’ ideas (e.g., difficulties, indications of high-level reasoning) as a basis for communal reflection through the following actions: making the challenge accessible to students; recording all students’ answers; inviting students to connect different solutions; questioning proposed ideas; and favoring the development of an inclusive learning environment (e.g., encouraging silent students to participate). As regards the existence of some patterns in teachers’ approaches to balance mathematical challenge and differentiation, our analysis reveals a dynamic interplay of actions moving back and forth between providing challenging questions and prompts. Far from being characterized as linear, this process indicates underlying ‘zig-zag’ patterns related to the complexity of teaching practice when the teacher aims to keep the challenge and at the same time to maximize learning opportunities for all students. This is an interesting finding that needs further exploration taking into account that in existing literature teachers’ attempts to enact highly demanding tasks have been characterized with an emphasis on the part of mathematical challenge at a global level (upgrading/downgrading, lowering/maintaining/increasing, Stein et al., 2000). Our analysis indicates

the need to take a more detailed look on teachers' actions and on the spot decisions while working at the intersection of mathematically demanding tasks and differentiation.

*In this paper we present and illustrate a framework for analyzing the relation between teachers' actions and students' meaning making in mathematics. We adopt a pragmatic perspective on learning, and a methodological approach using already analyzed material, to see whether and how the framework of epistemological move analysis can contribute when analyzing the relation between teachers' actions and students' meaning making. The results suggest that epistemological move analysis can be used to identify teachers' purpose in students meaning making in mathematics, by analyzing students' responses. Further, it makes it possible to identify what earlier knowledge students use, and how they use it, to re-actualize mathematical objects, relations and concepts.*

*Keywords: Mathematics teaching, meaning making, pragmatism, epistemological move analysis.*

## Introduction

The teacher plays a major role in making classroom talk the arena for learning mathematics and teachers' interactive strategies are central to how students become engaged in math-talks in a classroom practice (Walshaw & Anthony, 2008). To succeed in eliciting and extending students' mathematics, a teacher should encourage the mathematical activities of analyzing, making connections, and generalizing (Fraivillig, Murphy, & Fuson, 1999). It has been proven important that a teacher stimulates students to struggle with important mathematics by challenging them with non-routine tasks and trying to find out more efficient solution methods (Hiebert & Grouws, 2007). However, providing successful math-talks in practice can be challenging. Teachers tend to funneling (Bauersfeld, 1998) students' responses towards the answer they want, blocking them from being fully engaged in math-talk (Brodie, 2011). Also, rather than addressing problems in terms of the underlying concepts, students address problems mainly in terms of what they think that the teacher is expecting (Millar, Leach, & Osborne, 2001).

Talk-based teaching of mathematics is a complex teaching practice, calling for the need of theoretical constructs that take serious the social and interactive nature of teaching and learning (Lerman, 2000). However, concerns have been raised that a focus on social and interactive issues in mathematics teaching may steer away learning from content (Lerman, 2006). For instance, analyses of practices or activity systems common in sociocultural traditions tend to focus on what is done in a general objective (Bakker, Ben-Zvi, & Makar, 2017), which leaves little room for fine-grained analysis of how students make sense of mathematical content.

In the present paper we use a pragmatic perspective on learning (Dewey, 1929/1958) as a starting point, where meaning making is considered to emerge "in the process of doing and undergoing the

consequences of action” (Rudsberg, Öhman & Östman, 2013, p. 600). Based on this perspective the aim of this paper is to present and illustrate a framework that enables detailed investigations of teachers’ role in directing students’ meaning making processes of mathematics in talk-based teaching. The methodological approach in this paper is to use already analyzed material to see whether and how the framework can contribute when analyzing the relation between teachers’ actions and students’ meaning making. We aim to clarify and investigate both social and individual aspects of the meaning making process in mathematics, in a descriptive manner.

## Theoretical background

**A pragmatic perspective on meaning making:** The first question to be addressed is how to understand learning and meaning making in classroom practice. Often the visibility of such processes is seen as a central problem (Östman & Öhman, 2010), for example the problem of not knowing what the students have in mind. The problem of visibility is often connected to a view of learning as something mental, something that takes place in the student’s head hidden from the observer (Rudsberg & Öhman, 2013). However, here we take Dewey’s theory of action (Dewey, 1929/1958)<sup>1</sup> as a starting point in which meaning making and learning are understood in terms of people’s actions; something they do, in relation to the environment and the specific situation at hand. This can be seen as a way to dissolve dualisms, such as, for example, between the concepts of inner mind and reality (Garrison, 2001). Dewey (1929/1958) describes life as a process of constant change that contains an active phase, doing, and a passive phase, undergoing the consequences of action. Accordingly, meanings are seen as the way that humans respond to the environment and they are practical in the sense that “we use them as *means to consequences*” (Garrison, 2001, p. 284). Dewey (1929/1958) states that meaning “is not indeed a psychic existence; it is primarily a property of behaviour” (p. 179). Communication is seen as a coordinating activity in which the participants make something in common (Garrison, 2001). In this way, “meaning making emerges in the process of doing and undergoing the consequences of action” (Rudsberg et al., 2013, p 600) and in this process experiences continually changes. Continuity can be seen as the process where students re-actualise earlier knowledge in order to make meaning in a new situation. In the process of re-actualization earlier knowledge also transforms i.e., earlier knowledge is not perceived as fixed entities. Meaning making can thus be understood as a practical social process (Garrison 1995). Hence, in this pragmatic perspective meaning making and learning is possible to observe *in* students’ coordinating activities. Learning takes place when students develop a new or more developed and specific repertoire of coordinating activities (Semetsky, 2008).

**Epistemological move analysis:** Epistemological move analysis (EMA) is based on a pragmatic understanding of epistemology, where it is seen as both a part and a result of human practices (Wickman & Östman, 2002). This means that what counts as relevant knowledge is different in different practices and the knowledge that is considered to be true and valid is a discursive construction (ibid.). EMA focuses on the relation between the epistemological moves that the teachers make and the students’ meaning making (Lidar, Lundqvist & Östman, 2006). An *epistemological*

---

<sup>1</sup> For a more thorough elaboration of Dewey’ theory of action and its use, see, for example, Östman and Öhman (2010).

*move* can be defined as the way a teacher's utterance affects a student's meaning making in an educational situation, that is, the way a teacher's actions facilitate a certain meaning making. In other words, how a teacher's answer to, and/or evaluation of, a student's utterance affects the student's meaning making. EMA has been used in educational practices of, for example, science education (Lidar et al., 2006). From previous research, we can delineate at least five different types of epistemological moves: *confirming*, *re-constructing*, *instructional*, *generative*, *re-orienting* (ibid.)<sup>2</sup>.

As described above EMA enables investigations of the relation between the teacher's actions and students' meaning making in mathematics. In order to investigate students' meaning making EMA includes Practical Epistemology Analysis (PEA) (Lidar, Lundqvist & Östman, 2006). That is, EMA can be seen as a development of PEA with a specific focus on the role of teachers' actions. EMA aims at giving account of both the content and the processes of students' meaning making in relation to the teacher's moves. In the analysis of students' meaning making four central components are used; *encounter*, *gap*, *stand fast* and *relation* (Wickman & Östman, 2002). Teaching takes place in situations where students *encounter* their environment and interact with, for example, other students and the teacher. The interaction is made in relation to the purpose of the activity. That is, the first step of the analysis is to clarify what the student encounter and the purpose of the activity. In education, students sometimes do not immediately know how to proceed, i.e., the students cannot proceed by habit and a *gap* occurs. In teaching situations, a gap becomes visible when for example the teacher asks a question or when the students hesitate. In order for the interaction to proceed the gap needs to be filled, by, for example, responding to a question. This is done in the process of re-actualization. In the process of re-actualization the students bridges the gap by creating *relations* between their earlier knowledge, what *stands fast*, and the problem at hand. That is, the students' earlier knowledge becomes actualized in a new situation. The earlier knowledge becomes visible in the educational practise as the students use knowledge without hesitation and no explanations are needed. The relations created by the students constitute the content of the individual's meaning making.

In our analysis we focus on the relation between the teacher's actions and students' meaning making. The teachers' actions, for example, giving instructions, asking questions or making comments, can be seen as guidelines that direct the students' meaning making in a certain way. These actions made by the teachers indicate both what counts as knowledge and appropriate ways of acquiring this knowledge in the specific educational practice. Here it is important to notice that we categorize teachers' epistemological moves in terms of the function they have for the students' meaning making. On this account, we have analyzed whole events in order to clarify the differences between students' utterances before and after the teacher's actions. An event consists of a sequence consisting of three turns, including (1) a student's actions, (2) teachers' actions that encourage a student's action, and (3) a student's actions after the teacher's actions (Klaar & Öhman, 2014).

---

<sup>2</sup> The moves identified in this study will be described in the analysis; for a description of earlier identified epistemological moves see, for example, Lidar et al. (2006) and Rudsberg and Öhman (2010).

## Illustration of EMA in mathematics education

To illustrate epistemological move analysis we use two examples from Blanton's and Kaput's paper focusing on classroom practices in algebraic reasoning (Blanton & Kaput, 2005). These examples are rich in mathematical content, given that the characterization is built on features of algebraic reasoning. Blanton and Kaput aim to "understand those types of instructional practice that indicated a generative and self-sustained capacity to build on students' algebraic reasoning" (ibid, p. 416). From this study we have chosen examples from audio-taped classroom talks. To identify the teacher's purpose of these classroom talks, the authors have studied notes by and interviews with the teacher. By using epistemological move analysis we can study the relationship between the purpose that the teacher expresses and the purpose visible in how the student responds to his/her moves. Blanton's and Kaput's paper includes several examples of principles for task-design and indications on what kind of question the teacher should ask to promote algebraic reasoning. However, their intention is "not to address how June's practice affected student achievement; this would require a more detailed look at how her actions played out in the classroom and how students were involved" (ibid, p. 435). In this paper we aim to employ such a detailed look by analyzing how the teacher's epistemological moves direct and support students' meaning making. This way we can clarify students' meaning making concerning both process and knowledge content in the actual situation. Important to notice, however, is that we do not investigate whether or not this change is of long term.

**Algebraic treatment of number:** In reviewing homework of addition tasks, the teacher shifts focus to properties of even and odd numbers and, during this sequence, there is an *encounter* established between the teacher (June) and two students (Tony and Jenna). In the first part of this encounter a scheme of even and odd numbers is used. The teacher's purpose is that the students should find an algebraic principle of parity in adding odd and even numbers. This aim becomes visible when the teacher uses large numbers to guide Tony to use an algebraic principle instead of computation that specifies even and odd numbers. The transcript (ibid.) used in this illustration is the following: "June challenged a student's use of arithmetic strategy to deduce that  $5+7$  was even:

- 1     June:    How did you get that?
- 2     Tony:    I added 5 and 7 and then I looked over there [pointing to a visible list of even and odd numbers on the wall] and saw that it was even.
- 3     June:    What about  $45678+85631$ ? Odd or even?
- 4     Jenna:    Odd.
- 5     June:    Why?
- 6     Jenna:    Because 8 and 1 is even and odd, and even and odd is odd." (p. 422).

Teacher "spontaneously shifted the focus from computing sums to determining if the sum of two numbers would be even or odd. When students responded by first computing the sum to determine if it was even or odd, June began to use numbers that were sufficiently large so that students could not compute. Instead, they were forced to attend to the structure in the inscriptions themselves." (ibid, p. 417). The *gap* in this encounter is between the use of addition in order to determine if the sum is even or odd and the ability to use an algebraic principle in order to determine if the sum will be even or odd. The gap becomes visible when the teacher (line 3) uses large numbers.

The students are able to make arguments on the parity of sums of odd and even numbers without using computations. The *stand fast* can be regarded as computation of specific numbers and using the list on the wall to determine odd and even numbers. This is *re-actualized* into the ability to use numbers as placeholders, or variables, for *any* odd or even number. This change is made because of the teacher's epistemological moves in line 3 and 5. Together these moves enabled the student to change the way of determining if a sum of two positive integers will be even or odd. Hence, the student has made new mathematical meaning about the structure of the inscription itself in terms of an algebraic principle of even and odd numbers. This way the teacher's epistemological moves in line 3 and 5 are *generative move* as they have the function of generate students learning of algebraic principles and relations. The teacher's purpose becomes visible in line 5 since the response by the student in line 6 is built on an algebraic principle rather than on computation.

**Finding a mathematical formula:** In working with the concept of area, the teacher introduced an activity in which students should determine how many two-colored counters were needed to cover a large purple square. In this sequence we can conclude that it is an *encounter* between the teacher and four students (June, Mari, Zolan, Stephanie, Kevin) and also one more student (unidentified in the audio-taped recording), who may or may not be one of the other four students. The teacher's purpose is that the students reach an understanding of how to use length and width to determine the area of rectangular planar objects, i.e., finding a formula for the area. This purpose becomes visible in line 23 as it generates the concepts of length and width in line 24. The transcript (ibid.) used in this illustration is as follows: "June had the following conversation with her students:

- 13 June: Do I know how big the square is?
- 14 Mari: No.
- 15 June: What do you see [referring to the large square which students had covered with tiles]?
- 16 Zolan: Four columns, four rows.
- 17 June: [June then covered a desk with the large purple squares like those she had given students.] So, what would the area of the desk be?
- 18 Stephanie: Twenty-four big squares.
- 19 June: What if we found the area of this table [pointing to a large table in the room]?

One student suggested using a ruler. Kevin proposed to examine how many purple squares are in a row and in a column.

- 20 Zolan: Count how many [purple squares] are in the bottom row.
- 21 June: One, two, three, four, ... eighteen. [June counts out the number of purple squares in the bottom row.] And how many 18s do I need?
- 22 Kevin: Seven!
- 23 June: What's the best way to find area?
- 24 Kevin: You measure this way and that way [indicating length and width] and multiply.
- 25 June: What do you call "this way" and "that way"?
- 26 Student: Length and width!" (p. 428-429).

The purpose in this encounter is located between the use of square tiles for covering rectangular planar objects and finding a formula for area of such objects. In line 13 the teacher asks the students if they know the size of the large purple square after the students have covered it with tiles. However, the teacher's first question (line 13) does not have any function in terms of meaning making, since the student cannot bridge the gap that the question creates. Indeed, the teacher's question (line 13) is an action, but it is not an action that qualifies as an epistemological move. A *gap* between square tiles and the size of a planar object becomes visible when the teacher in line 15 asks the students to look at the square and explain what they see. This is an *instructional move* since the student's answer is describing what he (Zolan) can see and not mentioning anything on area. This means that the gap lingers. In the third question (line 17) the teacher explicitly asks the students to find the area of the desk. This is a *re-orienting move* since the students now are focusing on the total amount of squares rather than numbers of columns and rows. Here it *stands fast* for the student how to cover a square object with square tiles (line 18). This earlier knowledge is re-actualized in order to make new meaning to view area as a grid of square tiles. Hereby the students are able to fill the gap.

When the teacher explicitly asks the students to determine the area of another planar object (line 19), the gap changes. The new *gap* is between using columns and rows and finding the formula for area. Related to the change of gap the student also actualizes other earlier knowledge that becomes visible when the teacher asks the students to determine the area of yet a new object (line 19). Here the knowledge that *stands fast* can be regarded as knowing how to use columns and rows to cover a rectangular planar object. This is re-actualized when the student starts to investigate the grid in a new way by counting the numbers of squares in the bottom row (line 20). In this way the teacher's action functions as a *re-orienting move*.

Finally, the teacher makes two *re-constructing moves* (line 21 and 23). The first becomes visible when the student (line 22) shows awareness of the importance in comparing the total number of square tiles with the numbers of columns and rows. Thereafter the student (line 24) is able to relate number of columns and rows to create a formula for area. Finally, the students are able to fill the gap by finding a formula, in terms of length and width, for determining area of planar objects.

## Concluding remarks

The analysis shows how teacher's epistemological moves during math-talk is crucial for students' meaning making processes, both concerning the procedure (how) and the mathematical content (what). For example, in the first illustration the *generative move* deepens the student's mathematical knowledge in terms of an ability to build on algebraic principle rather than computation when determining even and odd numbers. We can conclude that the teacher enables the students to generalize (Fraivillig et al., 1999), which is done by challenging them to find a more general and efficient solution to the problem at hand (Hiebert & Grouws, 2007). By using EMA it was possible to identify how the students' earlier knowledge in this specific situation was *re-actualized* into the ability to use numbers as placeholders for *any* odd or even number. More explicitly, this re-actualization is made because of the teacher's epistemological move (line 3), made visible by the student's answer in line 6, where the latter uses numbers 1 and 8 as placeholders for odd and even numbers. By this re-actualization the student fills the gap that becomes visible by the teacher's

question in line 3. In this way the student has made new meaning about an algebraic principle of odd and even numbers. Here we stress that the contribution in using EMA is to point out what actually takes the meaning making a step forward, rather than analyzing certain approaches in forehand intended to promote specific motives. The strength in EMA is in the situational, rather than long term. However, in combining EMA with well-known strategies promoting algebraic reasoning, such as the framework used by Blanton & Kaput, sustainable learning perspectives may be closely related to situational and contextual perspectives.

This can be compared with our second illustration. In the first part of the transcript the teacher poses different questions with the purpose of enabling for the students to understand a formula for the area of rectangular objects. However, in the first part of the sequence the students answer the teacher's questions without re-actualizing any earlier knowledge about area. Instead they answer the question more in terms of what they think that the teacher are expecting (Millar et al., 2001). Important to notice here is also that the teacher's purpose, to understand how to determine area, isn't visible in the students' actions until later in the sequence (line 19-20). At the end of the sequence (line 24-26), after the re-constructing move, which also clarifies the teacher's purpose, the students re-actualize earlier knowledge that enables them to establish a formula for area. By using EMA we can identify that the teacher's purpose is not initially clear to the students. The students are not able to see how the general properties for area correlate to the teacher's purpose. The students try to answer the question (line 13) but are not able to fill the gap until the teacher changes character of the questions (line 23). This illustration can be seen as an example of funneling (Bauersfeld, 1998), with the consequence of students being partly blocked from being fully engaged in the talk (Brodie, 2011).

To summarize, using EMA, we *can* analyze the relation between teachers' actions and students' meaning making concerning process (how) and content (what) in mathematics. This way, EMA can contribute to the research on social and interactive processes in mathematics (Lerman, 2006). Further, EMA makes it possible to identify the role of teachers' purpose in students' meaning making in mathematics. However, it should be stressed that meaning making is seen as situational. We believe that the concept of re-actualization should get more attention in studying the role of teachers' actions for students' meaning making in mathematics. Re-actualization should not be misinterpreted as transfer or application, but rather as the process describing *what* stands fast in a certain encounter and *how* the students use knowledge that stands fast to create *new* meaning of mathematical objects, principles or concepts. Based on the present analysis, we claim that EMA offers analytical tools to enhance our understanding of the relationship between content and process in student's meaning-making in mathematics and the roles teachers' actions can have in providing directions for meaning-making.

# Mathematics teaching and teachers' practice: tracing shifts in meaning and identifying potential theoretical lenses

Charalampos Sakonidis

Democritus University of Thrace, Greece; [xsakonid@eled.duth.gr](mailto:xsakonid@eled.duth.gr)

*The paper reports on meaning shifts of the terms 'teaching' and 'teachers' practice' in mathematics education over time and presents three theoretical frameworks arguing for their advantages in studying mathematics teachers' instructional practice, an especially complex but relatively unexplored sociocultural activity. An exemplification is then offered through the exploitation of one of the theoretical lenses suggested in the case of the mathematics teaching practice of a primary school teacher, Antigoni. The results of the data analysis informed by the lenses employed revealed a dynamic and strongly contextual understanding of the teacher's teaching practice connecting her current with past and present practices of hers, a feature specific to the framework used.*

*Keywords: Mathematics teaching practice, mathematics teachers' practice, meaning shifts, theoretical lenses.*

## Introduction

The identification of TWG19's exact research interest has been of concern since its birth in 2016, not only because of the obvious need to avoid overlapping with neighbouring CERME Working Groups but mainly for reasons of conceptual clarity and coherence. This concern is evident in the writings of the members of the leading team in several occasions. Thus, in Sakonidis et al. (2017) we argued that the work reported in the first TWG19 sessions at CERME10, related predominately to teachers operating on critical aspects of mathematics classroom instruction or inquiring into their own teaching suggested a shift of research focus from teachers to teaching. In a memo circulated to potential participants of TWG19 in CERME11, Mosvold, one of the members of its leading team, commenting on the shift of the group's research interest to mathematics teaching and teachers' practice(s), pointed out ambiguities in the use of the terms 'teaching' and 'practice' evident in their weak conceptualizations and the poorly addressed theoretical underpinnings of the latter. The meaning concerns related to the two central constituents of TWG19 focus were again raised in a chapter written for a volume on the twenty years of CERME research (Skott, et al., 2018), suggesting a social approach to attributing meaning to these constructs that will allow making sense of the corresponding practices in relation both to the contingencies emerging as classroom processes unfold and to the social practices of which they are part.

The paper is an attempt to further the above discussion. It first reports on the meaning shifts of the terms 'teaching' and 'practice' in mathematics education over time. It then presents some potentially useful theoretical frameworks for studying mathematics teaching and teachers' practice. An attempt to exemplify such a study is then provided through the analysis of an extract of a mathematics lesson taking place in a Greek primary classroom. The paper concludes with some moving ahead thoughts and considerations.

## **Mathematics teaching and teachers' practice(s): meaning advancements**

Despite the significance of teachers' activity for pupils' learning but also for their own professional learning and development, as it is gradually acknowledged, research on teaching remains underdeveloped. Most of the relevant studies seek to understand or support teachers' actions that highlight mathematical processes and inquiry into what it takes for teachers to engage students in actively learning mathematics. The actual meaning of teachers' activity related to students' learning is left unchallenged.

The term 'teaching' has been used with different meanings in mathematics education, nurtured by different motives and purposes. Often seen as inseparable from learning, teaching tends to be related to teachers' actions, like orchestrating instructional activity, managing tasks and regulating communication within a classroom but also beyond it. Irrespectively of its meaning, teaching signals a highly complex activity that unfolds under conditions of uncertainty (given then unpredictability of human beings). Research such as that of Hattie (2015) documents the complexity of teaching: the challenge of making sense of the interplay between different aspects of it, the difficulty to appreciate institutional realities and the complexity of accountability which systems, parents and the general community demands. Teaching takes place through teacher's perception of, and interaction with its context which shapes his/her moment-by-moment decisions about what is important to teach, how students learn, how to manage student behavior and so on. This complexity of teaching is burdened in the case of mathematics teaching, given its highly valued learning outcomes worldwide and the difficulties teachers and students face in pursuing them due to intervening epistemological, cognitive sociocultural as well political factors.

Research on teaching over the past several decades has evolved from an emphasis on teacher characteristics to a focus on teachers' actions/behavior, to cognitive views of teachers as decision-makers and reflective practitioners (Grossman, Hammerness, & McDonald, 2009a) and more recently to teachers as participants in the practice of teaching (e.g., Lerman, 2013). This later trend enables making sense of teaching as a human activity situated in social settings. Furthermore, drawing on sociocultural theories, allows incorporating both intellectual and technical activities and encompassing both the individual practitioner (the teacher) and the professional communities (teachers, stakeholders of education, educators, and so on) (Chaiklin & Lave, 1996). For Wenger (1998) a practice includes "all the implicit relations, tacit conventions, subtle cues, untold rules of thumb, recognizable intuitions, specific perceptions, well-tuned sensitivities, embodied understandings, underlying assumptions, and shared world views. Most of these may never be articulated, yet they are unmistakable signs of membership in communities of practice" (p. 47).

Practice in complex domains like teaching, and especially mathematics teaching, involves the orchestration of understanding, skill, relationship and identity to carry out particular activities with others in specific settings. When people learn a practice, they enter a historically defined set of activities developed over time by others (Engeström, Miettinen, & Punamäki, 1999). As members of a profession, practitioners have a responsibility to their colleagues (Shulman, 1998), reinforcing the collective meanings of professional practice. They also use aspects of their own personalities, as well as their professional identities, as an intimate part of their practice (Grossman et al., 2009b). Based

on the above considerations, teaching is seen as teachers' multifaceted practice aiming at promoting students' mathematics learning in a variety of settings, shaped by the expectations and norms of these settings, learned from and shared with other practitioners and preserved by the traditions of educational thought and practice within which it has developed and evolved.

### **Mathematics teaching and teachers' practice: promising theoretical perspectives**

The research interest of TWG19 delimited by the meaning attributed to the terms 'teaching' and 'practice' in the previous section is clearly served by the sociocultural tradition of teaching and learning mathematics. The available theoretical frameworks tend to see teaching as learning in practice, thus drawing mainly on the known theories of learning as well as on social theory to formulate their own perspective. Three among these appear to readily lend themselves to TWG19 research focus: Wenger's approach to learning as developing an identity through participation in a community of practice, Cultural-historical activity theory's focus on the learning that emerge in the institutionalized contexts of practical activities culturally and historically mediated within a society and recently Skott's participatory approach concentrating on patterns in individual teachers' participation in different social practices. Below, a brief presentation of each of these frameworks is offered highlighting elements that are related to TWG19's research interest.

Wenger (1998) describes community as "a way of talking about the social configurations in which our enterprises are defined as worth pursuing and our participation is recognizable as competence" (p. 5). These configurations are the basis of practice which is always social, whereas communities and learning are always socio-historically situated in webs of social relations. In a Community of Practice (CoP) members negotiate joint enterprises, ways of engaging with each and repertoires or languages for meaningful interactions and progress towards their goals. Belonging to a CoP, or developing identity within it, involves engagement, imagination and alignment. Thus, for example, in practices of mathematics learning and teaching, participants engage in their practice alongside their peers, use imagination in interpreting their own roles in the practice and align themselves with established norms and values. A teacher learns through a continuous process of 'becoming' in the context of the relationships in her classroom and with her colleagues within the education system and the society of which she is a part, as well as in relation to her own history, which is also socially situated. How these relationships are configured constrains and affords learning for particular teachers and communities of teachers.

Human activity is "a system with its own structure, its own internal transformations, and its own development" (Leont'ev, 1979, p. 46), activated by a motive and comprising goal-directed actions carried out by means of operations. Within an activity system, actions are mediated by tools and signs but also by or through community, rules of activity and division of labor (Engeström 2001). Individual and group actions within the activity system are seen as independent units of analysis that become understandable only when interpreted against the background of entire activity systems. Engeström (2001) considers contradictions and tensions as sources of change and development leading to transformations in activity systems. Individuals begin to question and deviate from the established norms, and the object and the motive of the activity are re-conceptualized to embrace a radically wider horizon of possibilities than in the previous mode of the activity. This, which Engeström calls

‘expansive learning’, gives rise to new knowledge and practices for a newly emerging activity system. Teaching practice is subject to extra-school influences such as policies emanating from school systems, teacher networks, district educational leadership and so on constituting activity systems with varied goals, motives, tools and rules which unavoidably shape teachers’ practice (s).

Skott (2013) developed a ‘patterns-of-participation’ (PoP) framework that aims to identify trends and developments in the recurrent “and possibly routinised ways in which the teacher engages with the students and the contents” (p. 548). He claims that teachers engage in everyday classroom interaction by reinterpreting and transforming past and present practices in the process. Hence, their contribution to the interaction is shaped by their participation in other significant discourses (mathematical, meta-mathematical or related to broader issues of the social situation), depending on the meaning attributed to the interaction itself. Thus, in each classroom interaction “the ‘pieces’ form a fluctuating pattern that indicates the shifting significance of different, prior discourses and practices as well as the dynamic relationships between them” (p. 548). Skott argues that teachers negotiate classroom practices by interpreting possible contributions to the interactions symbolically. To do this, they draw on their own schooling practices, interactions with colleagues, parents or the school management, theoretical discussions in their professional development program and so on.

I believe that the three frameworks presented above offer different but equally challenging perspectives to study mathematics teaching and teachers’ practice. CoP framework allows examining this practice as the enterprise of a particular community (related to school), CHAT within broader sociopolitical systems/environments and PoP as the result of the teacher’s contingent pattern of participation across practices and discourses (even beyond school). In the next session I employ PoP to present the case of Antigoni, the teacher in the uploaded video (for CERME11’s participants to work on) as an illustration of how the above three frameworks can help explore mathematics teachers’ practice exhibited during classroom teaching.

### **The use of PoP: the case of Antigoni**

Antigoni, a primary teacher of 17 years of teaching experience, graduate of a Mathematics as well as of a primary education Department, is very committed to her profession; critically confident with respect to her mathematical but also her pedagogical knowledge and skills as evidenced, for example, in her open class for anyone who wishes to attend her mathematics lessons; and scientifically and professionally active as documented by her Master’s degree in Education, a considerable list of publications and conference contributions, as well as her regular participation in classroom intervention projects and professional development courses related to Mathematics.

Antigoni’s teaching practice has often been studied over the years of our cooperation from within various theoretical perspectives and in the pursue of different research questions. The lesson that the uploaded extract comes from is part of the data being collected in the context of a project focusing on the mathematics teaching practice of five primary teachers, one of them is Antigoni, including interviews, (video and audio) taped meetings before and after planned lessons and field notes. The analysis presented below aims to identify the roles Antigoni enacts in the practice emerging in her mathematics teaching.

Antigoni always liked mathematics as well as teaching. As a university mathematics student, she would choose courses that would offer opportunities “to dive in issues related to educating people in thinking mathematically, a question still haunting me”. And she still talks fondly about a University teacher, “the only one”, who offered optional courses on problem solving where she felt for the first time confident enough “to pose my own questions, to bring in the class my own problems, collaborate with others to solve a problem and feel OK to fail to find the solution to a problem for days!” (Antigoni as a student).

She is very enthusiastic about her being a mathematician and a primary teacher “in a territory where most fellow teachers fear ... or are anxious when teaching mathematics ... often stuck to the textbooks provided by the government and going by the book”. She was also worrying initially about mathematics teaching, but she then thought:

Come on, you love mathematics! (laughs) ... This is your chance to prove that primary mathematics is more important but also harder to learn ... and teach because... a primary teacher lays the foundation of a solid mathematics learning trajectory! (Antigoni as teacher)

Antigoni approached us in the Primary Education Department of the nearby University about twelve years ago asking for help “as I was feeling like trying hard but with no results!” This is where a fruitful collaboration started originally with few visits in her class and gradually incorporated small projects (e.g., putting aside the textbook, introducing investigative tasks for small groups, discussing specific areas of the curriculum, e.g., introducing fractions in the 3<sup>rd</sup> grade, diverting from the ‘desirable’ sequence of teaching the content of the mathematics curriculum, inviting fellow teachers to work together in her class, explaining to teachers what she was trying to do, and so on).

I still remember how suspiciously Maria looked at me (a very close friend and fellow teacher in the same school) when I asked her to join me in reading the relevant literature, plan and teach together my class the idea of ratio, an idea used to be taught much later that year (laughs).... Also, the parents of ... who were furious for ‘wasting valuable time on ‘experimentations’. I am still anxious when I meet parents for the first time to talk to them... And of course, Headmaster ... who never liked me for ...messing up his school! (Antigoni as a colleague)

Nowadays, Antigoni works with a group of at least half of the teachers of the school, planning and implementing shared teaching sessions, runs almost every year a Students’ Mathematics’ Club, works with us in organizing professional development courses for the teachers of her school with a specific focus every year and this year plans to invite teachers of other schools in a two-days meeting to share with them what they do (Antigoni as a professional).

With respect to teaching mathematics, Antigoni believes that primary mathematics is for all students who should be taught in ways that would “allow them to go deep into the heart of mathematics” through tasks that make sense to them, boost their confidence in “acting mathematically”, support their conceptual understanding and “help them feel safe”. As far herself is concerned, she thinks that her teaching “is OK if you think in constructivist terms but still away from being able to genuinely promote collective learning of mathematics”. In the uploaded extract the mathematical focus is on the concept of fraction and especially on the idea that the whole is made up of the sum of all its fractional units. Antigoni addresses the whole class with the question “how many fractional units

make up the whole” but things get wrong when she asks for the symbolic writing of the idea (Antigoni as a teacher).

- Teacher: How would I write it to make a whole pie out of these (three) pieces?
- Student: (comes to the blackboard) The whole pie?
- Teacher: Yes, the whole pie. Let’s see.
- Student: (writes the fraction three thirds –  $3/3$ )
- Teacher: Ah!! And how to you make up these three thirds?
- Student: From three pieces.
- Teacher: How do you write that down? Do write ‘equals’, how do you write that down in mathematics?
- Student: (writes the equal sign to the right of  $3/3$ )
- Teacher: How exactly do you make three thirds for this pizza?
- Student: In ones?
- Teacher: What do you mean? What are the ‘ones’ here?
- Student: One piece
- Teacher: Write down the “one piece”
- Student: One plus one plus one. (writes  $3/3=1+1+1=3$ )
- Teacher: Do you agree? One plus one plus one is three. Is it the same as what he’s written on the board? Maria?
- Maria: Three out of three pieces.
- Teacher: Can we see that by the way you’ve written it? How can we show that it’s three out of the three pieces? Let’s see.
- Student: (erases  $1+1+1=3$ )
- Teacher: Let’s help him a little. How do we write each piece of this pizza? Can someone help? Chryssa?
- Chryssa: One third!

The discussion goes on for a little more, the student writes  $3=1/3$  but it’s obvious that he doesn’t really follow. Watching the episode afterwards Antigoni expressed her disappointment for the students’ difficulty but argues that the idea is not an easy one and insists on ‘giving space’ to students to communicate their thoughts.

Summarizing, Antigoni’s narrations of herself as a committed and determined professional relate to the challenges offered by both mathematics and teaching in exploring and making sense of the world as well as communicating with others, pursued and enjoyed by her from early on. Collaboration, team work and issues of knowledge accessibility are at the heart of Antigoni’s professionalism, sometimes

constrained by factors external to her teaching practice. She acknowledges in her teaching practice students attempt to communicate their thinking, encourages ‘epistemologically correct mathematics’, thus valuing mathematics as a scientific discipline but prioritizes students’ confidence and inquiring approaches. Finally, her strong ties with mathematics appears to weaken any challenge to her professional self.

## Concluding remarks

Despite its importance, it’s only recently that teachers’ instructional activity per se attracted the interest of the research community, being seen until then mostly in relation to students’ learning. Shifting the emphasis from teachers to teaching, which is viewed as a social practice, the relevant research employs predominately sociocultural and especially participatory perspectives to understand the emerging character of this practice “taking into consideration working contexts, meanings and intentions ... the social structure of the context and its many layers – classroom, school, community, professional structure and educational and social system” (Ponte & Chapman, 2006, p. 483). These activities mutually structure and frame each other to constitute the teaching practice (Skott, 2013).

The theoretical frameworks available in the literature for studying the practice of mathematics teaching as presented above recognize the high level of complexity associated with it. Within this complexity lie affordances and constraints, shaped by culture, the environment and people in it. This suggests that no single framework is likely to capture the complexity of the mathematics teaching practice across widely variable contexts. A variety of dynamic perspectives is necessary which will help us disentangle and understand the ever-evolving outcome of individual and communal acts of meaning-making (by both teachers and students) characterizing the practice of mathematics teaching. Antigoni’s narrations revealed the dynamic relationship between present and past teaching and other practices and hence discourses she participated, without allowing though for its development to be traced. A more careful consideration of mathematics teaching as a social practice being informed by teachers’ participation in (not necessarily compatible) discourses beyond classroom setting, predominately but not exclusively related to mathematics, might offer challenging lenses for making better sense of how these discourses are enacted and interact both at the micro and the macro level within the classroom, shaping teachers’ moment-to-moment teaching practice(s).

## Pre-service teachers' experiences in selecting and proposing challenging tasks in secondary classrooms

Leonor Santos<sup>1</sup>, Hélia Oliveira<sup>1</sup>, João Pedro da Ponte<sup>1</sup>, Ana Henriques<sup>1</sup>

<sup>1</sup>Instituto de Educação, Universidade de Lisboa, Portugal; mlsantos@ie.ulisboa.pt; hmoliveira@ie.ulisboa.pt; jpponte@ie.ulisboa.pt; achenriques@ie.ulisboa.pt

*This study aims to know if pre-service secondary school mathematics teachers are able to select, adapt or design appropriate challenging tasks and what are the main challenges that they face when working with challenging tasks in the classroom. The study is qualitative, based on observation and interviews. The participants are two preservice teachers at the 2<sup>nd</sup> (and final) year of their master of teaching degree. The results show that the preservice teachers, albeit facing several constraints, were able to find and adapt interesting tasks. They also identified several challenges in this activity, in the planning phase, during students' autonomous work and, most especially, during the whole class discussions.*

*Keywords: Challenging tasks, preservice teachers, planning, students' autonomous work; whole class discussions.*

### Introduction

What students learn in mathematics mostly depends on the mathematical experiences offered to them in mathematics lessons (NCTM, 2014). Particularly powerful to promote the development of mathematical understanding are challenging tasks that require students to establish connections among different aspects of mathematics, formulate their own solution strategies and explore several pathways to solutions (Sullivan et al., 2015). These kind of intellectual activities requires new pedagogies in teaching mathematics and, consequently, raises new challenges to teachers, namely putting demands on teachers' knowledge (Sullivan & Mornane, 2014), on teachers' understanding of tasks, particularly their potential and demands (Foster & Inglis, 2017), and on teachers' classroom practice (Ponte & Quaresma, 2016). Most studies addressing this issue involve in-service teachers, but we want to understand which main issues arise when pre-service teachers (PTs) are encouraged to propose challenging tasks in the classroom. This was the general issue that prompted us to develop a study with two pre-service secondary school mathematics teachers, aiming to answer the following research questions: (i) What are the nature of the tasks selected, adapted or designed by the PTs? and (ii) What are the main challenges that PTs face when they propose and enact challenging tasks?

### Theoretical framework

The centrality of tasks in mathematics classroom instruction has been recognized both by theoretical perspectives and empirical research (Shimizu et al., 2010). Several curricular documents around the world recommend the inclusion of "rich" or challenging tasks in mathematics teaching in order to promote students' high level thinking such as problem solving and reasoning (NCTM, 2014). However, different conceptualizations on the nature of such tasks have been proposed by distinct authors, and using different language, for instance "rich", "authentic" or "complex" tasks (Shimizu et al., 2010). The profusion of terms, and particularly the lack of explicitness concerning their meaning, often does not contribute to develop a clear understanding in the educational settings

about the core characteristics these tasks should have. As Foster and Inglis (2017) found in their study with a large number of mathematics teachers in the UK, teachers express contrasting perspectives about the nature of the tasks, namely having one task classified both as demanding and non-demanding or as engaging and non-engaging by different teachers.

One of the most well-known taxonomy for tasks is the one by Stein and colleagues which includes four levels of cognitive demand to characterize the mathematical tasks: two for lower-level and two for higher-level demands (Stein & Smith, 1998). According to the authors, the tasks that exhibit a lower-level of cognitive demand may be targeted at *memorization* or to use *procedures without connections*, that is without explicit attention to concepts and understanding; those rated as higher-level involve complex thinking and reasoning processes and are denominated as *procedures with connections* and *doing mathematics*. We have adopted the definition of cognitively demanding tasks proposed in this framework. Tasks may assume the form of problems, exploratory or inquiry tasks.

The practice of proposing and enacting challenging tasks that are set and maintain the intended level of cognitive demand has showed problematic for many teachers (Stein & Smith, 1998), and attention has been given to teacher education programs that might support teachers in developing new practices (Ponte et al., 2017). One of the main issues is the need to move to new lesson structure that support a student-centred approach and value classroom discourse, namely through the promotion of whole-class discussion as an effective enactment of challenging tasks in the classroom (Russo & Hopkins, 2017; Sullivan & Mornane, 2014). As the study by Crespo (2003) shows when they are “left to their own devices preservice teachers’ tendencies were to pose unproblematic problems to their pupils” (p. 264). It seems important that PTs are able to articulate their vision about teaching, namely the need to diversify the nature of the tasks that are usually proposed in the classroom, making possible for them to collaborate in the future with other teachers in developing new teaching practices (Towers, 2010) that may include challenging tasks.

Two important aspects of the teaching practice with challenging tasks are the questions the teacher poses to the class and how he/she sequences it (Mata-Pereira & Ponte, 2017) and providing appropriate enabling prompts for those students who experience difficulties in the task, such as, “reducing the number of steps, simplifying the complexity of the numbers or varying the forms of representation” (Sullivan et al., 2015, p. 126). In the case of PTs who lack the experience of teaching, these actions may even more challenging. Teacher education programs need to provide PTs with opportunities to learn within a “practice-based” experience that allows them to develop skills targeting specific practices (Forzani, 2014) such as selecting and supporting the enactment of challenging tasks in the classroom.

## Context of the study and methods

This study was carried out with two PTs on the second year of the Master of Teaching degree at Universidade de Lisboa. During their field experience, PTs were invited to select challenging tasks to propose in two lessons that they were about to teach in their school placement, that would be observed by their respective university supervisor (the two first authors). By then, PTs had attended the teacher mentor classes for about one month and had the opportunity to interact with students, but this was the first time they were responsible for teaching a lesson by themselves. The request for teaching with challenging tasks was not a surprise to PTs since, in alignment with current

curriculum orientations for mathematics teaching, this masters' program provides extensive discussion on inquiry-based perspectives on mathematics teaching (Ponte et al., 2017).

Five PTs were attending the course. For this study, we select as cases two PTs that we regard as more contrasting considering the focus of our study: Marta and Magdalena, both fictitious names. Marta is 22 years old and graduated in Applied Mathematics and Computation. She developed her teaching practice in a private school, in an urban area of Lisbon. She taught a 12<sup>th</sup> grade class (age 17) with 13 students who are interested and motivated for studying, show good achievement in mathematics (only two have medium achievement, all the others have high). They are usually focused on the proposed mathematical work and try to help each other when working in pairs. Magdalena is 24 years old and graduated in Applied Mathematics. She teaches a 10<sup>th</sup> grade class (age 15) with 17 students in another private school near Lisbon. The students are heterogeneous regarding their school achievement, 35% had a negative grade in Mathematics at the end of the 1<sup>st</sup> school term and show many difficulties in the topics covered in previous years. Most of them show lack of study habits and are not very participative in class.

Following a qualitative research approach, data collection processes included the observation of two lessons with video recording, pre- and post-lesson reflections audio recorded with PTs, post-lesson written reflections, and their lesson plans. A first reflection (R1) occurs before each observed lesson. Immediately after, and preceding the post-lesson reflection (R2), there was a discussion about the lesson with the supervisor and mentor. Content analysis was used to analyse data, with pre-defined categories for the nature of the tasks (Stein & Smith, 1998). In the case of the challenges faced by the two PTs there were no predefined categories but we had as reference the review of literature presented in the theoretical framework.

## The nature of tasks

In both observed lessons, PTs proposed one task to the class. The tasks sought to introduce or create the need for new knowledge, in particular to relate the signal of the second derivative with the direction of the concavity of the graph of a function (Task 1, Marta) or they were problems (Tasks 1a, 1b and 2, Magdalena). Task 2 by Marta was a problem of optimization, which sought to lead students to feel the need to know how to differentiate trigonometric functions. In both tasks, the students in Marta's class used the graphic calculator. All tasks included several questions and can be rated as *High Cognitive Demand* with different level of intellectual challenge (Table 1).

**Table 1. Characterization of the tasks concerning the level of intellectual demand**

Task 2 - Marta Tasks 1a and 2 - Magdalena	Procedures with connections	Requires "some degree of cognitive effort. Although general procedures may be followed, they cannot be followed mindlessly".
Task 1 - Marta Task 1b -Magdalena	Doing Mathematics	Requires "students to access relevant knowledge and experiences and make appropriate use of them in working through the task" and "considerable cognitive effort".

Magdalena's task 1a and 2 and Marta's task 2 are characterized in the group of *Procedures with connections*, because they demand to apply previous knowledge in new situations (to calculate

measurements from a geometric object; to study a trigonometric function in a way similar to what they had done for other types of functions), requiring a transfer of knowledge. The other tasks present characteristics of *Doing mathematics*, since they require considerable cognitive effort, such as to apply to the second derivative of a function what they had learned about the first derivative (Task 1, Marta) or to establish diverse relationships between geometric objects, demanding a good visualization capacity, in particular, students need to use their knowledge about volumes of solids (cube and pyramid) (Task 1b, Magdalena).

PTs' perspectives about the tasks are similar to our analysis, but they do not use the same terminology since this taxonomy was not explored with them. The aspects they mention are that their students were not used to solving these kinds of tasks, they were called to develop mathematical ideas that had not yet been covered in class, and required processes of reasoning more complex than usual:

The task is challenging for students because it addresses the second derivative and its geometric meaning without first introducing it “theoretically”. (Marta, pre-lesson R1)

They are challenging tasks because they confront the students with unexpected things, that they are not used to, and lead them to think and reflect on how they might get there. I think (...) this helps them to develop their mathematical reasoning. (Magdalena, pre-lesson R1)

For Marta, although the two tasks have in common being challenging, there are differences between them. While she considered task 1 as “a more oriented task” (that students have to answer a sequence of questions), she regards task 2 as “a problem” (Marta, post-lesson R 2). Task 1 is very structured, appealing mainly to calculations. Task 2 leads students to look at the proposed situation in a global way. For Magdalena, the proposed tasks are mainly problems, with the exception of a few questions from one of the tasks (task 1b) proposed in the first lesson which she considered to be exploration or investigation.

### **Pre-service teachers' challenges when working on challenging tasks**

Regarding planning for these lessons, the two PTs did not hesitate to say that *to obtain challenging tasks* was quite a challenge for them: “The biggest challenge before the class was to build from scratch task 1 and to find a second task that would be challenging, suitable and relevant to this class” (Marta, post-lesson reflection 2). They searched in textbooks, but found no task with the sought features, so they also used other resources: Marta looked at materials of the Association of Mathematics Teachers brought especially by the teachers of her school. Magdalena made an extensive search in the internet and in several textbooks. For the second lesson she felt that it was difficult to find a suitable situation. When finally she found a situation that seemed promising to design the task, she still needed some guidance from her supervisor to guarantee it could be solved by different processes.

In their lesson plans, the two PTs expressed the intention to adopt an exploratory approach to teaching either by her own initiative in the case of Magdalena, or by the supervisor's suggestion, in the case of Marta. In both cases, PTs made plans that took into account the different phases of an exploratory teaching approach: introduction of the task, students' autonomous work and discussion with the whole class, accompanied by a synthesis of key ideas.

In all lessons, the introduction of the task was of short duration. Students were informed that they would work autonomously during a determined period of time and then there would be a whole-class discussion. At this stage of the lesson, no questions were raised by the students. It has not been observed, or referred by Marta or Magdalena, any challenge during this phase of the lessons.

During the students' autonomous work, the PTs circulated, accompanying the students' work, namely by answering some clarifying questions. Magdalena assumed that her role in these classes should be to support students through questioning, not telling them exactly what they should do. Nevertheless, she recognizes that this type of intervention sometimes has not the intended effect, in particular with students with greater difficulties. So, one of the challenges in these lessons is to know what *type of intervention* she should develop in line with the diversity of students in the class:

I stand for not giving the answer and instead to guide students. But sometimes I'm afraid to say something that leads them to the answer and that they figure out [the answer]. (...) I think it's important that they think for themselves but when I am in front of students with more difficulties sometimes I don't know at which point should I just guide and guide... To me, that is most difficult. (Magdalena, post-lesson R2)

Associated with this phase of students' autonomous work, these PTs mention the challenge of time management in supporting different groups. Magdalena due the unexpected difficulties that came out in the first task, had to spend too much time with some students in order to understand what they were doing, to identify their errors and to think of questions or prompts that could help. Consequently, she has spent a lot of time with some students, limiting the possibility of supporting other students. Marta also mentions the challenge of "making a good management of the time I am spending with each group" (Marta, post-lesson R2), which she relates with the decision of when to leave the group and let those students work autonomously:

Even if students in the group still remain with some doubts, I can give some guidance but I also need to know when to let them working and struggling by their own and come back to them later on (...) after supporting other groups (...) [But] to me, this decision is not always very easy: to give some guidance and to know when I should leave the group. (Marta, post-lesson R2)

The *time to devote to this stage* of autonomous work on the task and, consequently, the decision of when it is appropriate to close this phase and move to the whole-class discussion it is also an issue identified by these PTs:

[I verified] that the students were not working as I had previously planned, which is not necessarily negative. The time that I had set was showing to be too short. It was a challenge that I had to face: to decide whether I should to move for discussion or not. (Marta, post-lesson R1)

The whole-class discussion presents also some problems to these PTs, such as *to take advantage* from this phase of the lesson, to explore it in a developed way. In the first lesson, Marta solved on the board the first questions of the task with the contributions of the students, and they did not raise any doubts, apart from some calculation problems. In fact, the real discussion began with question 1.5. when Marta questioned: "Who is able to explain to the class what is demanded in 1.5.?" A student began to answer, but Marta said: "Use your own words to explain what is asked here. It is a

question that raised a lot of confusion”. Marta supported the discussion about the calculation of the limits, and simultaneously the graph of the given function and the tangent lines at given points were constructed in Geogebra. After the students’ explanation, Marta also gives her own but there is no effective discussion. The discussion happens, in each moment, essentially between Marta and a certain student; there is no discussion among the students.

In the first moment of the discussion of task 2 (Figure 1), Marta begins by asking a group of students to explain what they did:

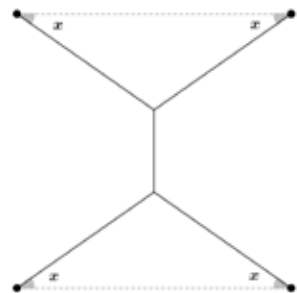

S: We tried to define a formula for the wire length.

Marta: Do you begin immediately to think in getting a formula?

S: Initially we tried a little by eye.

Marta: And what was your perception?

S: At the junction of the two triangles, if they joint at a midpoint (Marta, lesson 2)

<p>1. Four villages are located on the four corners of a 1 km side square. When making a new cable installation linking the four villages, the company responsible for the project came to the conclusion that the most economical solution is the one of the following figure. It is known that this type of installation is considered for <math>x \in \left[0, \frac{\pi}{4}\right]</math>.</p> <p>1.1. “As the angle <math>x</math> increases, the total length of cable required decreases”. Do you agree with this statement? Justify.</p>	
--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------

**Figure 1. First question of task 2 in Marta’s lessons**

Marta decided not to use the material that she had prepared previously to support the discussion with the whole class and asked the students to go to the board to explain what they have done. She tries that each group presents his strategy, although the decision on *which should be the sequence* of students’ work for presentation to the class was also a challenge for her:

In the second discussion, as there were already so many groups knowing [how to solve the task] (...) knowing where to start [this was an issue]: [should I begin] by those who have not got there or [should I] give opportunity [to the others],.. I think this was also a challenge... (Marta, post-lesson R2)

Magdalena also had the intention to promote whole-class discussion after the students solved the tasks. In the first lesson, in face of students’ struggling where they had many computations to complete, there was no time for the majority of students to solve the second part (Figure 2), which was the one that had more potential for discussion. In the second lesson, the students also took much more time than predicted to solve the task. In the face of lack of time, only one student presented his solving strategy and there was no interaction with other students apart from some questions for some clarification. So, the capacity to have a real *perception of the difficulty that the tasks may present to students* has been for Magdalena a restriction to develop a fruitful whole class discussion.

In the figure it is represented the cube  $[ABCDEFGH]$  and the pyramid  $[ABCDE]$ . It is known that  $\overline{EC} = \sqrt{12} \text{ cm}$ . Determine the volume of the part of the cube that is not occupied by the pyramid.

Figure 2. Task 1b in Magdalena's lessons

## Conclusion

In this study, both PTs were able to find and adapt interesting tasks. However, they faced the constraint of finding or designing challenging tasks aligned with the specific mathematical topic they had to teach during their practice. They considered the tasks challenging since they were different from what is usually proposed to these students and appealed to mathematical ideas that students had not yet covered, being a means for new learning or to promote processes of reasoning that are more complex than usual (NCTM, 2014). This indicates that the teacher education environment provided the two PTs with the intellectual resources and dispositions necessary to identify and adapt challenging tasks to propose in their classes, contributing to their development of a shared idea of the nature of these tasks.

For an effective enactment of challenging tasks in the classroom, the two PTs adopted a new lesson structure (Russo & Hopkins, 2017; Sullivan & Mornane, 2014), identifying several challenges in this process. In planning, although always considered in the lesson plan, they see the *anticipation of students' difficulties in solving the task* as underdeveloped due to their lack of experience in teaching as they do not have a deep knowledge of the students (Magdalena). During students' autonomous work, the *time and the support to give to students* were problematic for both PTs, namely in order to maintain the intended level of cognitive demand, as it has been found in other research with in-service teachers (Stein & Smith, 1998). During the whole class discussion, Marta faced challenges such as *selecting and sequencing the presentation of student's strategies*, knowing which ones to use, the most appropriate ways of doing it, namely when most groups had already solved the proposed questions correctly; *involving* all students in the discussion, even those who have more difficulties or are more reserved; *promoting a broad discussion among the students* which requires knowing how to break with the teacher-student-teacher circle; and *going deep in the exploration of what students say*, especially of what is mathematically important, but is difficult to understand for some students (Mata-Pereira & Ponte, 2017). From these results, we may say that the teacher education program supports teachers in developing new practices (Ponte et al., 2017) especially in moments of planning. During the lessons, where it is necessary to take decisions in action, the pre-service teachers faced diverse challenges, most of them similar to those of in-service teachers.

*The main goal of this paper is to understand how teachers' actions in classroom influence the way students solve a task involving quantitative additive reasoning. The study used a qualitative methodology and a teaching experiment was carried out. One task was proposed to two different classes (2<sup>nd</sup> and 3<sup>rd</sup> graders), of the same public school, with two different teachers. The results show that 2<sup>nd</sup> grade students solved the task with ease, but 3<sup>rd</sup> graders had difficulties. Teachers' actions of guiding and challenging and how teachers developed the process of communication in classroom do influence students' performance.*

*Keywords: Quantitative reasoning, teacher's actions, students and teacher interaction.*

### Introduction

This paper reports on part of the research carried out by a project focused on flexible calculation and quantitative reasoning developed by teachers of the Higher Education Schools of Lisboa, Setúbal and Portalegre in Portugal. The research question for this paper is: How do the teachers' actions in whole class discussion influence the way students solve a task involving quantitative additive reasoning? We present the whole class discussion of a task involving quantitative difference in a 2<sup>nd</sup> and a 3<sup>rd</sup> grade classes and analyse how the teachers' actions of guiding and challenging influence students' quantitative additive reasoning (Thompson, 1993).

### Theoretical framework

The communication processes that take place in the classroom, as well as the tasks proposed to students, are essential aspects of teachers' practices (Ponte & Quaresma, 2016; Boaler, 2003). Franke, Kazemi and Battey (2007) stress the importance of processes that support students' language development, like resaying - saying the same idea in a different way, usually closer to formal mathematical language, questioning the meaning and supporting the development of students' mathematical thinking. The questions posed by the teacher are a fundamental aspect of communication, with inquiry questions being particularly important, admitting a range of legitimate responses. Related to discourse, Ruthven, Hofmann, and Mercer (2011) propose a dialogic approach as "one that takes different points of view seriously, encouraging students to talk in an exploratory way that supports development of understanding" (p. 4-81). Thus, the decisions that teachers make are crucial, especially those that are taken during the whole class discussions, a particular form of classroom work used in exploratory teaching (Ponte, 2005). It is important that different points of view be considered and that students be encouraged to explain and justify their reasoning and solutions, thus developing, with the teacher's support, their understanding (Ruthven, Hofmann, & Mercer, 2011). In order to have a fruitful whole class discussion, Stein, Engle, Smith, and Hughes

(2008) stress the importance of teachers anticipating the way students may think, monitor their work, collect the pertinent information, select the issues to deal with during the discussion, think about the sequence for students' interventions, and establish connections among different solutions during the discussion. This preparation is important, but a good discussion may involve many aspects that cannot be foreseen before and teachers need to be prepared to face them (Cengiz, Kline & Grant, 2011; Ponte & Quaresma, 2016). Ponte, Mata-Pereira and Quaresma (2013) present a framework for analysing a discussion where they distinguish four fundamental kinds of actions related to mathematical aspects: (i) Inviting, seeking to initiate a discussion; (ii) Supporting/Guiding to lead students to present information, making questions or observations; (iii) Informing/Suggesting, introducing information, giving suggestions, validating students' responses; and (iv) Challenging to encourage students to produce new representations, interpret a statement, establish connections, or formulate a reasoning or an evaluation.

Quantitative reasoning involves reasoning about relationships between quantities. It “is the analysis of a situation into a quantitative structure — a network of quantities and quantitative relationships” (Thompson, 1993, p. 165). The relationships, in this kind of reasoning, are established between quantities. Numbers and numeric relationships are of secondary importance. Thompson (1993) connects the notion of quantity to the idea of measure, clarifying that quantities when measured have numerical value, but the reasoning does not depend on their measures. For example, we can think about the heights of two persons determining who is taller than the other without having to know the actual values. “Quantities are attributes of objects or phenomena that are measurable” (Smith & Thompson, 2008, p. 101), but “what is important is relationships among quantities” (Thompson, 1993, p. 165). A quantitative operation is the comparison between two quantities to find the excess of one relative to the other and the quantitative difference is the result of the quantitative operation of comparing two quantities additively. According to Thompson (1993), numerical difference, as the result of subtracting, is not synonymous to quantitative difference, which is an item in a relational structure. A quantitative difference is not always evaluated by subtraction and subtraction can be used to compute quantities that are not quantitative differences. For Smith and Thompson (2008), quantitative reasoning implies “to focus on quantities and how they relate in situations” (p. 121). Therefore, teachers' actions should lead to discussions of quantities, not numbers. “The goal is to get students to describe situations as they see them” (p. 122). Teachers “should imagine how their students might describe the situation differently and what conceptual difficulties might be lodged in their descriptions” (Smith & Thompson, 2008, p. 121). In whole class discussion teachers should invite students to share their solutions, guide and support them through questions focused on situations description, and challenge them to explain their reasoning. Thus, the discourse used by teacher is a key aspect accounting for students' understanding of quantitative relationships.

## Methodology

This study follows a qualitative approach framed in an interpretative paradigm (Bogdan & Biklen, 1994). It is focused on the educational processes and the meanings of the study participants. The project adopts the modality of teaching experiment conceived with the purpose of developing in students the flexibility of calculation and the quantitative reasoning.

The data were collected from two classes in a public primary school in Lisboa, with 26 students each – a 2<sup>nd</sup> grade class (7-8 years old) in November 2015 and a 3<sup>rd</sup> grade class (8-9 years old) in October 2015. The Project team defined a sequence of tasks involving addition and subtraction problems. The task sequence was previously discussed and analysed with the two classroom teachers having been made minor adjustments.

Both teachers are female expert teachers with a large experience of teaching. The two teachers are considered good teachers of mathematics and both try to develop an exploratory teaching in their classes. However, teachers are quite different in what concern their relationship with mathematics. Catarina (2<sup>nd</sup> grade teacher) likes mathematics and did a specialization in mathematics education. Catia (3<sup>rd</sup> grade teacher) always had trouble with mathematics that she wanted to overcome, that's why she wanted to participate in this project. The two teachers are friends, work together, and they had been invited, at the beginning of the project, to collaborate with the project team members and both accepted.

The names of students and teachers have been changed to ensure confidentiality. The data collection was done through participant observation, complemented with field notes and videotaping of the classes, including whole class discussion. The students' productions were also collected. In the part of the exploration of the tasks, the videotaping focused on two pairs of students in each class, selected by habitually verbalize their reasoning among themselves.

The task was the sixth of a sequence. In the previous lessons and in the first part of this lesson the students had solved other tasks where they had to make comparisons in gains and losses problems. The task solved by 2<sup>nd</sup> and 3<sup>rd</sup> grade students was the same, but the magnitude of numbers was adapted accordingly. Figure 1 shows how the task was presented to the 2<sup>nd</sup> grade students.

**Figure 1: The task solved by 2<sup>nd</sup> grade students.**

For the 3<sup>rd</sup> graders the numbers were: Monday: +50, -20, +10, +20; Tuesday: +30, -40, +60; Wednesday: -74, -94, +90. The students should select a smiley or a sad face circling it depending on their sense of whether there would be more gains or more losses at the end of the day(s). The students should also find the quantity representing how many marbles they won or lost at the end of the day, that is, the final quantitative difference. They did not work with the notation of negative

numbers before this task. The analysis focuses on whole class discussions and especially on categories of action coming from Ponte et al. (2013) and Smith and Thompson (2008) frameworks: *the inviting action* seeks to get students to share their solutions; *the guiding action* seeks to get students to describe the situation, modelling it and focusing on quantities; *the challenging action* seeks to encourage students to explain the quantitative relationships.

## Results

**2<sup>nd</sup> grade:** The teacher introduced the task saying to students “This new proposal has only the gains and losses in different games, let's see what happens at the end of each day”. First, students solved the task in pairs, being videotaped the pairs Paulo and João and Luís and Lúcia.

Paulo seemed to deal easily with the quantitative difference whether it was an excess or a deficit. This facility is evident in the way the task was carried out by Paulo and João pair. They did it very quickly, in two minutes, although João followed Paulo's notes (he wrote "+8" after 3 days, and rectified later to "+1", when looking at Paulo's sheet). As the researcher got closer, Paulo explained that he looked at the nulls ("nulls", for example, -2, +2), having calculated only the remaining ones.

Luís and Lúcia approached the task using a different strategy. They gathered the gains, they joined the losses, and only then did the comparison. In the situation related to Wednesday, the students surrounded the sad face, understanding that at the end of the day, the player lost marbles. But they were stuck in the numerical record because it was a loss. With the researcher's guidance, when she came close, they wrote "-17; +9".

In the whole class discussion, the most presented strategy was to add, on the one hand, the gains, and on the other, the losses, and then determine the difference. For example, for Tuesday, the teacher invited the Marta and Mónica pair to go to the blackboard and record their results. They wrote quickly: " $+9 - 6 = +3$ " and drew a 'smile'.

Mónica: We did +9 which is what won +6+3.

Teacher: And the other 6?

Mónica: Out of what he lost: the 4 and the 2.

Teacher: How do you get 3? (addressing the class)

Students: The difference between 9 and 6 is 3 to win.

First, the teacher *guided* students through a question that led students to focus on losses (quantitative difference). Then *challenged* students to explain the results: “How do you get 3?”. Here the students seemed to dominate the situation and the teacher's questioning led students to explaining their quantitative reasoning.

But the teacher *challenged* the class, trying to have another explanation:

Teacher: Is there another explanation?

Paulo: Yes, the +6, -4 and -2 annul themselves. (The teacher records on the blackboard:  $+6-4-2=0$ )

Paulo: And only +3 left over.

This idea of 'annulling' was used by other students in the following situations, correctly by many. Paulo had the opportunity to present his explanation when the teacher asked for other explanation.

**3<sup>rd</sup> grade:** The teacher introduced the task saying that now they had to look just for gains and losses and should find what happened at the end of each day. Then, students started to explore the task in pairs, and showed difficulties confounding the notion of quantitative difference with the absolute amount of marbles, increasing these difficulties for Wednesday.

At the whole class discussion, the teacher *invited* Vítor to present his solution for Monday:

- Vítor: So, he had 50 on Monday...
- Teacher: Won...
- Vítor: 50, but then he lost 20; then he won 30 and won. He was happy. (...)
- Teacher: Does everyone agree?
- Students: Yes.
- Teacher: How many marbles did he win?
- Students: 60. [And Vítor puts the sign +, +60]

Vítor began by confusing the notion of quantitative difference with the absolute amount of marbles: when he says "he had 50", he seems to assume that the player began the game of marbles with 50 marbles. But, the teacher *guided* him, focusing on quantitative difference when she referred to "won" and after Vítor took a discourse centered on the gains and the losses describing the situation.

Concerning Tuesday, Rui explained his solution on the blackboard.

- Rui: Then, on Tuesday, he won 30 more, he had 60. Then on Tuesday he lost 40. (...)
- Teacher: In general, he won more or lost?
- Rui: He won. (...)
- Teacher: So, overall, how much did he win?
- Rui: I think he got 60. [Rui records  $30-40+60=60$  on the blackboard] (...)
- Student A: It's wrong! It's fifty because 30 minus 40...
- Alexandre: From 30, you cannot take out 40.

Again, there is a conceptual confusion between the quantitative difference and the absolute amount of marbles: "he had 60"; "he got 60"; "From 30, you cannot take out 40". The teacher tried to focus on global balance "In general, he won more or lost?" and "So, overall, how much did he win?" [*guiding* action]. Rui, confronted with the reactions of his peers, corrected his solution adding the gains ( $30+60=90$ ) and subtracting the lost marbles ( $90-40=50$ ). At the end, Rui circled the result 50, concluding that the player won 50 marbles on Tuesday.

Then, the teacher *invited* Alexandre to present his solution for Wednesday:

- Alexandre: I saw we had 94.

- Teacher: So, let's start at the beginning ... on Wednesday, in the first game, what happened in the first game, Alexandre?
- Alexandre: He lost 74.
- Teacher: He lost 74, and after, in the second?"
- Alexandre: And after he lost 94.
- Teacher: And after he lost 94 ... and after he won ...
- Alexandre: He won 90.
- Teacher: 90. And then, with the data we have there what did you do? Tell us.

The dialogue began by focusing on the modelling of the situation, with the teacher *guiding* about what was going on the three games on Wednesday. Alexandre continued explaining his solution: " $94+90=184-74=110$ ", justifying the addition of 94 and 90 because "94 is the largest number and 90 was the second largest number". Alexandre tried to have an explanation for the computations, not for the situation. Again, the teacher tried to *guide* him, seeking to focus his reasoning on losses:

- Teacher: But why did you take out 74 now?
- Alexandre: Because I had already spent these numbers; it was just missing 74, I went to take them out.
- Teacher: You were to take out that because it was missing ... but Alexandre, in fact, he lost 74 and lost 94... (...) What does this mean?
- Alexandre: He got less than zero.
- Teacher: I can only loose what I have...

On Wednesday, the balance between gains and losses is negative: after the three games, the player lost 78 marbles. The quantitative difference in this situation requires ignoring the absolute number of marbles and Alexandre was not able to deal with a negative point of departure ("He got less than zero"). Alexandre seems to consider 94 as the initial number. The teacher revealed difficulty *to guide* the student's reasoning referring to the assumed need of knowing the initial number of marbles ("I can only loose what I have..."). In this situation, Jaime offered himself to explain. He added all the numbers (" $74+94+90=258$ ") and went to the blackboard to explain why he added 74 plus 94:

- Jaime: Because 74 and 94 were what you had before.
- Teacher: 74 and 94 were the marbles he had, because he can only loose, we can only loose what we have, isn't it? I cannot loose 74 marbles if I had nothing. (...) My friends, the 74 and 94 what were they?
- Jaime: That's what they had.
- Teacher: They only lost because they had them.

The students confused the quantitative differences with the initial number of marbles. Again, the teacher tried to *guide* students focusing them in the modelling of the situations. However, the teacher could not reorganize her discourse when the situation became more complex. Catia had difficulty to *challenge* students in a way that they could understand the quantitative relationship

without knowing the absolute amounts of marbles. An impasse was created, and, in the meantime, the class had to end, it was time to break.

## Discussion

The results show that the two classes reacted differently to the task. 2<sup>nd</sup> graders seem to do it without any difficulty. In contrast, 3<sup>rd</sup> graders had difficulties, namely the fact that they did not have the initial number of marbles. These difficulties increased for Wednesday where the losses are greater than the gains, as no student did it correctly. From the beginning of the solution, while the 2<sup>nd</sup> grade students added the losses and gains, 3<sup>rd</sup> grade students started to operate with numbers, apparently not thinking about the meaning of their procedures. This was not usual in the class because, as stated earlier, both classes used to do exploratory work in mathematics.

Catia, the 3<sup>rd</sup> grade teacher, started to guide students focusing on the modelling of the situation, but confronted with the students' answers, her questioning could not overcome the students' conceptual understanding of quantitative relationships. Although she had solved the task before, trying to anticipate students' responses, she was not able to deal with it when the situation became more difficult (on Wednesday). She began guiding the students to the description of the situation, as advocated by Smith and Thompson (2008), but at the end she got lost as her students. She repeated a statement which did not help as it was focused on the absolute numbers involved ("we can only lose what we have") and this did not help students to solve the situation because it probably reinforced the confusion between the relative change of losses (-74-94) and the absolute amount of marbles ("what you had before"). She seems to have not understood students' difficulty and was not able to retelling the situation (Franke et al., 2007). On the contrary, the 2<sup>nd</sup> grade teacher, Catarina, was always at ease with the situation, challenging her students in different ways, much more focused on the quantities in presence.

## Final remarks

As Ruthven et al. (2011) state, the questions posed by teachers are fundamental aspects of classroom communication. Catarina and Catia have a similar inviting action seeking to initiate the discussion and to get students to present and share their solutions. However, they differed regarding ways of communication concerning this specific task, with Catarina's questions being more focused on the quantities and how these are related to the situation (Smith & Thompson, 2008). So, how teachers develop the process of communication in classroom has a crucial role in students overcoming the challenging situation related to quantitative difference. Thus, 2<sup>nd</sup> grade students were able to focus on quantitative difference, looking at gains and losses, and dealing, naturally and comprehensively with negative number notation. On the contrary, the 3<sup>rd</sup> grade students were not able to disconnect from arithmetic operations and the need to consider an initial number and they were unable to focus on quantitative reasoning. So, it could be argued that the 2<sup>nd</sup> grade students were able to conceive a quantitative difference independently of numerical information about quantities (Smith & Thompson, 2008). For us, this situation is intrinsically linked to teachers' actions and more specifically to the ways teachers guided and challenged students through questioning so that they latter could advance in their quantitative reasoning process. This study allows to emphasize the important role of teacher's actions of guiding and challenging in

promoting students' ability to reason with quantitative relationships, even when the initial values are unknown.

# Contradictions in prospective mathematics teachers' initial classroom teaching as sources for professional learning

Konstantinos Stouraitis<sup>1</sup> and Despina Potari<sup>1</sup>

<sup>1</sup>National & Kapodistrian University of Athens, Greece; [stouraitisk@gmail.com](mailto:stouraitisk@gmail.com),  
[dpotari@math.uoa.gr](mailto:dpotari@math.uoa.gr)

*In this paper we study the first field experiences of a prospective mathematics teacher in a secondary school. Using Activity Theory we focus on contradictions emerging in the process of designing and enacting lessons, the sources for these contradictions and the potential impact on teacher learning. The two prevailing tensions related to students' engagement in doing mathematics and students' unexpected difficulties can be interpreted as contradictions between the actual and intended status of the object and between the teacher's goals and the mediating tools. Sources for these contradictions seem to be the contradictory teacher's experiences from the teacher education context and typical characteristics of mathematics teaching in Greek secondary schools. We find that the teacher becomes more aware about these contradictions and the different possibilities to deal with them.*

*Keywords: Activity theory, initial field experience, contradictions, professional learning.*

## Introduction

The transition from university teacher education to school reality is a complex process that involves challenges and tensions for the prospective teacher. Research has focused on this process, initially considering beliefs and knowledge (e.g. Potari & Georgiadou-Kabouridis, 2009; Skott, 2001; van Zoest & Bohl, 2002) while more recently teacher identity (Losano et al., 2017). Both the early and the more recent studies show that prospective and novice mathematics teachers' tensions are related to the various constraints of the school reality that often contradict to the images of innovative teaching approaches that are promoted in teacher education. In the study of Solomon et al. (2017), these tensions are related to the fact that teacher education programs offer an ideal way of teaching that is far from the school reality where emphasis is often given in achieving good results in mathematics. Bridging the gap between theory and practice in early school placement of prospective and novice teachers is necessary for facilitating smooth transition from university to school.

Losano et al. (2017) also talk about the tensions and contradictions that first year secondary school teachers face in their attempts to adopt innovative teaching approaches in the complex reality of school and mathematics classroom. They claim that this first teaching period offers very rich learning opportunities for the novice teachers as they reflect on their prior experiences and they project to their future career. Their findings indicate that the novice teacher of their study faced contradictions that in some cases were overcome while in others they remained conflicts. In particular, several past and present voices participated in the process of developing this teacher's professional identity. They also show that sometimes novice teachers align to the identities afforded by the existing mathematics teaching at schools while they also introduce transformations in teaching. This parallel way between innovative approaches and school established practices has also been reported in earlier studies

(Potari & Georgiadou-Kabouridis, 2009). Research has also indicated that curriculum resources that align with reform oriented practices and the interaction between the interns and the mentors are crucial factors supporting the intern's teaching development (van Zoest & Bohl, 2002). The study of Nolan (2016) also shows the constraints novice teachers face to use inquiry teaching approaches when the school reality is different from what they wanted to do. Although they recognize the limitations of the existing school and classroom structures, they keep silent and they do not take actions to change it.

All the above studies show that prospective and novice mathematics teachers face tensions while trying to enact innovative teaching approaches in their first teaching. Dealing with these tensions they use teaching approaches that may vary from reform oriented to rather traditional. Looking for interpretation of those contradictory behaviours we begin to recognize the role of context in this complex process. In our paper we attempt to address this complexity by focusing on the tensions that a prospective secondary school teacher faces in her initial classroom teaching and the ways that she deals with these tensions. In particular we address the following questions:

What are the contradictions that a prospective teacher faces in her initial teaching experiences and which are their sources?

How does this prospective teacher deal with these contradictions and what does it imply for her professional learning?

## **Theoretical background**

We adopt Activity theory and in particular the Engeström's (2001) perspective to study the contradictions, their sources and the process of dealing with them. Activity is collective, tool-mediated and it needs a motive and an object while it is realized through the actions – goals and operations – conditions (Leont'ev, 1978). Activity in our case is the teaching of mathematics at the secondary school with students' learning as the central motive. The subject is the prospective teacher Karen who performs actions (both in her planning and classroom enactment) related to specific goals that she makes explicit in the discussion she has with the researchers about her planning. These actions become operationalized through the tools she employs and the conditions under which teaching takes place. The institutional, social and classroom contexts are conditions on which teaching is developed. Tensions and contradictions are the driving forces for the development of the activity and in our case of mathematics teaching. Contradictions are historically accumulated structural tensions within and between activity systems. These tensions lead to changes in the activity, and in particular they emerge when a new element comes. Contradictions may refer to different elements of the activity system such as tools and object or communities and tools (Engeström, 2001). In our case the new element can be the innovative approaches promoted in the teacher education program that the prospective teacher attempts to enact in the rather traditional mathematics teaching history that characterizes mathematics teaching in the Greek secondary schools. Contradictions in the research related to mathematics teaching concern pedagogical, professional or epistemological issues and they emerge in the teachers' decision making process (Potari, 2013; Stouraitis, 2016; Stouraitis et al., 2017). Studying their content and their sources allow us to have access to the practices that Karen participates when she experiences them and tries to handle them.

The process of overcoming contradictions in the AT perspective is linked to the expansive cycle of Cole and Engeström (1993), a developmental process containing internalization and externalization in repeated cycles. In the internalization the subject carries out routinely the activity, while the emerging contradictions promote the subject's self reflection and the search for solutions. This externalization can lead to adoption of a new model for the activity that is also implemented by other subjects. As our study is mainly exploratory and our focus is on one prospective teacher that we interviewed and observed her teaching for a rather short time we cannot talk about a full cycle of expansion. However, initial indications of externalization that can be seen as signs of professional learning can be identified in our case and we recognized them in our analysis through Karen's attempts for innovations, her critical questioning on existing teaching practices and her projections on future changes that she could do into her teaching.

## **Methodology**

### **The context of the study**

In this case study we focus on Karen, a prospective secondary school teacher towards the end of her undergraduate studies. Karen studies mathematics at the university where she also attends mathematics education courses that aim to provide theoretical knowledge but to link it to mathematics teaching and learning at school. At the period that the study began, Karen was doing a course on teaching and learning problem solving and a course related to field experience where she observed lessons at school and she taught herself three lessons. Two of these lessons were in the context of an Erasmus+ project (EDUCATE) focusing on the design and enactment of mathematically challenging tasks that meets all the students' learning needs. Karen taught these two lessons in a state upper secondary school in December 2018 in the class of the first author. From March to May 2018, Karen did her internship in the same school. The first author of this study, the classroom teacher, acted as mentor for Karen while the second author was the teacher educator supporting Karen at the university. Both contexts in teacher education and school placement support reform oriented approaches.

Karen "always wanted to do this job [mathematics teacher]". She valued teaching from her experiences as a student at school, where one of her teachers was "close to us [the students]" and made connections between mathematics and other contexts. Also, Karen has prior teaching experiences as a private tutor preparing students for the class or university entrance examinations where a more procedural approach to mathematics is expected.

### **Data collection and analysis**

Karen conducted two lessons in the context of the university course and EDUCATE, and three more lessons as part of her internship. She attended several lessons by the classroom teacher and her peer Ken. Informal discussions were taking place after each lesson. The data for this study include two videotaped and transcribed lessons, field notes for all five lessons, students' worksheets, audiotaped and transcribed interviews before and after her lessons, online communication (emails), and two interviews in the beginning and the end of the internship. All these data were generated from December 2017 to May 2018. Analysing the data, firstly, we identified Karen's goals and the undertaken actions, the emerging tensions and Karen's attempts to overcome them. As indicators for the emerging tensions we used Karen's sayings about her worries, such as her uncertainty about

students' engagement, or about something that bothered her as for example a student response that did not expect. Tensions were grouped and interpreted as contradictions. For example, one group of tensions was related to time pressures and was interpreted as a contradiction between the tools used by Karen and the rules that regulate the school work.

## Results

In the process of planning and enacting teaching, Karen experienced several tensions. These tensions related with Karen's goals to engage all students in doing mathematics, students' difficulties, time pressures, and Karen's sensitivity towards students' emotions. Here, we focus on the first two as prevailing tensions in this period and because these tensions seem to trigger Karen's learning.

### Contradiction between the actual and intended status of the object

Classroom management and students' engagement are sources of tensions for Karen during her first teaching experiences. These tensions may be explained by Karen's no prior teaching experience, the big differences between students' achievement in the specific classrooms and her ambitious goal to engage all students in doing mathematics.

These tensions are expressed by Karen's worries if the students "will finally be able to deal with the tasks", if they will recognize the aim of modelling and a purpose of doing mathematics. They are also expressed as Karen's desire to succeed in her choices about classroom management. A challenging decision was to try to engage a group of five students which "do not want to learn mathematics" and "they have not any relation with mathematics, neither knowledge, nor interest".

We can interpret these tensions as manifestations of a contradiction between the actual students' mathematical engagement (the object of the activity) and students' mathematical learning as Karen's intended outcome of the teaching activity.

Karen deals with these tensions mostly through the design of the tasks and the forms of classroom interaction she orchestrates. The tasks were: modelling situations like the renovation of a house as context for forming and solving linear equations and the investigation of a crime as framework to use properties and different representations of exponential and logarithmic functions; logical puzzles; and typical school tasks like solving quadratic equations by using the formula and translating formulas and ordered pairs to graphs and points and vice versa. As sources that inspired the task design about modelling Karen mentions the university courses she attends. For the more typical school tasks she refers to the internet and classroom textbook and to discussions with friends and peers. There were lessons where the autonomous group work of students prevailed, while others were mostly conducted by whole class discussion with short time spaces to work individually or in pairs. She also used specific strategies to promote students' involvement, for example she asked students to write their answers on a piece of paper and show it in the class and she asked them to play a language game, complementing a phrase with letters collected for each equation they solved. As sources inspiring her decisions about classroom management Karen mentions her teachers and especially some strategies and games they used in the classroom, her involvement in collective sports and activities that "helped me [her] to understand the importance of group work". Nevertheless, she says that some mathematical topics must be presented by the teacher, because "it cannot be done differently", implying that she

does not know any other way to carry out teaching topics that include “introduction of something new, or understanding the steps of a proof”. After the second lesson Karen says that a pattern for teaching mathematics should be “teaching [teachers exposition and discussion], applying the procedures individually ... and [later] some problem solving or modelling tasks with students work in groups”.

In her last lesson Karen seems less stressful, although her goal to engage all students is still strong. She identifies and describes her feelings in the classroom talking about “the burden of being on the board”, and saying “there were times I was speaking, noticing students and thinking something else simultaneously. It is another level of multitasking”. In a next interview explains: “Multitasking is what you do all the time in the 45 minutes in the classroom”. She thinks that “your preparation and planning helps you improvising” because “there are too many factors in this time. Students’ responses, questions you don’t expect, your worksheet does not function as you expected, which word to use...” In her last teaching she had “too many thoughts. Thoughts connected with my actions and words ... like cartoons, these moments I thought I had multiple personalities, all talking to me ...” For her future as teacher, Karen thinks that she should be “always trying to find new ways of teaching, to develop, to inquire”.

Karen deals with the contradiction between the actual and the intended status of the object with the tasks she gives to the students and with her choices about the classroom orchestration. She mostly draws on innovative approaches like modelling processes, group work and playing games. Most of them come from Karen’s participation in the teacher education program and reform oriented approaches she experienced as student or as intern teacher attending the teaching of practicing teachers. Nevertheless, there are cases where Karen follows more traditional teaching approaches often met in mathematics classrooms in Greek schools. In this process Karen enhances her reflection becoming more aware about her decisions and actions in teaching and about the importance of lesson planning in the enactment of her goals. We cannot talk about Karen overcoming the contradiction, but she becomes more aware about it and she searches for “effective” ways to deal with this.

### **Contradiction between the teacher’s goals and the mediating tools**

Several tensions that Karen experienced are related with unexpected students’ difficulties. These emerged in the lessons and in some cases they could be explained in terms of Karen’s actions and the tools she used. Here we focus on students’ difficulties in relation to the tools Karen used in her teaching.

These tensions are experienced by Karen as unexpected students’ queries, misunderstandings or difficulties to proceed in the task. For example, in the first lesson, the written description of the task was complicated, requiring more explanations. In the fourth lesson, investigating a crime, students should solve an exponential system to find  $k$  and  $c$  in the expression  $T(t) = T_0 + c \times e^{-kt}$  consuming time and disrupting the focus on modelling process. In a previous lesson, answering why  $D$  must not be negative in the expression  $(x + \frac{b}{2a})^2 = \frac{D}{4a^2}$  Karen gives a rather procedural explanation that the amount under the square root must not be negative, although her goals are conceptually oriented.

We can interpret these tensions as manifestations of a contradiction between Karen's goals and the tools she used either as tasks or as explanations. While Karen's declared goals focus on conceptual understanding of mathematics, the tools she uses do not support these goals, on the contrary they orient students towards more procedural approaches.

Karen experiences these tensions as students' difficulties, not as contradictions between her goals and the mediating tools. Thus, she responds to them providing additional explanations and support or giving time. For example, she considers finding  $k$  and  $c$  as time consuming but not as disrupting from her modelling goals. She considers students' difficulties with locating points on a graph rather as a procedural difficulty to find a point than not understanding the translation between graphical and algebraic concepts and relations. Responding to the perceived difficulties Karen tries to reduce time or to give short exercises for students to solve. In the discussions after the lessons Karen explains her responses involving the mathematical content and the ways this content is usually taught. For example, on her explanation that the amount under the square root must not be negative, she says that "this is the proof ... this is the mathematical way to do it" adding that "a part of mathematics must be taught doing mathematics". The teacher educator, the classroom teacher and her peer challenge Karen's interpretations providing more conceptual explanations and approaches. Karen discusses and accepts these possibilities, not without resistance. For example, she says "you may need more time [to find  $k$  and  $c$ ], but this is in fact the mathematical modelling". After enacting the lesson in two different classrooms she thinks that "[to reduce the time] I could give  $c$ , so they should only find  $k$ ".

Although Karen's initial responses are rather procedurally oriented, in the discussions with the teacher educator, the classroom teacher and her peer, she appears open to other approaches and interpretations. In some cases an ambiguous shift has identified: Karen seems to adopt more conceptual approaches as potential ways to respond to the certain difficulties in the future. For example, ending the discussion about the task requiring the parameters  $k$  and  $c$ , she says that she could also think to give students  $k$  and  $c$ , and in another teaching period to come back and say "let's see how this is done in reality" implying how  $k$  and  $c$  can be calculated in a real situation.

The contradiction between goals and mediating tools seems to emerge as contradiction among the different Karen's experiences and communities she participated. Her conceptually oriented goals are based on her participation in the teacher education program and the context of the internship. In the last interview she says that through these experiences she has changed the way of thinking, especially "to think not only the time [the time planning of the lesson] but also the way a student thinks ... I have developed in setting my goals, considering how students think ...". Procedural approaches may come from her experiences as student and from her involvement in teaching as private tutor. For example, after the second lesson she says about her choice to spend time providing explanations on the blackboard: "there are some mathematical issues that you must teach this way, [students] to understand how we step from one to the other". Although Karen initially does not see any contradiction between her goals and the tools, in the discussions seem to open some possibilities for her awareness and future shifts. This was often expressed as possible change to the task, like the aforementioned change with  $k$  and  $c$ , or changes to the given answers, like focusing to the square in

the first part of  $(x + \frac{b}{2a})^2 = \frac{D}{4a^2}$  to explain the requirement  $D \geq 0$ . In the last interview, Karen

mentions as negative feature in teaching “the noise ... that is what you do [your actions] to impede your goals”. She says that it almost happened to her in some lessons, but she refers only the excessive use of the context without including procedural oriented tasks or responses blurring her goals about students’ conceptual understanding.

## Conclusions

Like the findings of other studies (Potari & Georgiadou-Kabouridis, 2009, Losano et al., 2017) Karen’s first enactments in the school classroom include both innovative and more established practices. This finding cannot be interpreted by the differences between the school context and the teacher education program, since both supported reform oriented approaches. We do not disregard the institutional factors that may imply a more traditional way of enacting the lesson in the school classroom, neither the ideal way to consider teaching in a teacher education program. But the specific context of Karen’s early school placement was focusing on students’ conceptual understanding and involvement in doing mathematics. Karen’s participation in different communities may support an interpretation for her mixed practices. Her experiences from the classroom teaching as a student and later as a private tutor, her participation in communities of university students discussing issues about teaching are also sources for Karen. These communities are also interacting with other communities without an immediate relation to mathematics teaching and learning (athletics, theatre) but seem to have a role in Karen’s way of becoming a teacher. Karen’s approach of the motive of the activity, that is the students’ mathematics learning, is influenced by these past and current activities and communities she participates. Similar findings are also reported for in service teachers (Stouraitis, 2017).

The tensions Karen experiences as worries, pressures and students’ difficulties are manifestations of contradictions fuelled by the aforementioned different approaches to teaching practice. Contradictions between the actual and the intended status of the object and between the teacher’s goals and the mediating tools, are two main groups of the emerged contradictions. The subject (Karen) has a prevailing role in these contradictions through the intended status of the object, the goals and the use of tools. Karen tries to overcome most of the tensions she experiences, although she does not identify all of them as contradictions. In line with other studies, the teacher deals with some of the contradictions aiming their overcoming, while other remain as tensions. But in the process of planning, enacting, reflecting and discussing her lessons and some tensions, Karen becomes more aware about contradictions and the different possibilities to deal with them. In some cases, a shift appears, rather as a potentiality to undertake a different action than a clear change. Additionally, this shift is verbally expressed by Karen when she talks about her development through her first teaching experiences and her learning. We consider these shifts as indications of self reflection and search for solutions, a crucial aspect of the cycle of expansive learning (Cole & Engeström, 1993).

The interaction between the interns and the mentors is recognized as a crucial factor related to teaching development (van Zoest & Bohl, 2002). In our case, discussions before and after the lessons with the teacher educator, the classroom teacher and Karen’s peer appear to be a supportive context for Karen’s reflection. These discussions were inquiry oriented, without a predefined intended outcome and promoted Karen’s reflection and growth of awareness. In this context Karen expressed

the aforementioned shifts. Karen's growing awareness and shifts and mostly the way she considers her future career can be interpreted as indicators for a developing professional identity. And this process seems to be initiated and supported by the collective context.

# Analyzing a novice teacher's instructional actions in response to unexpected moments in teaching

Rukiye Didem Taylan<sup>1</sup> and Merve Esmer<sup>2</sup>

<sup>1</sup>MEF University, Faculty of Education, Istanbul, Turkey; [tayland@mef.edu.tr](mailto:tayland@mef.edu.tr)

<sup>2</sup>Darüşşafaka Schools, Istanbul, Turkey; [merve.esmer@dek.k12.tr](mailto:merve.esmer@dek.k12.tr)

*This study investigated instructional actions of a novice teacher in 6<sup>th</sup> grade mathematics classrooms during unexpected moments of teaching. The teacher was selected as a case due to her commitment to lesson planning and her interest in creating meaningful mathematical discussions. Unexpected moments of teaching are defined as moments when there is an interruption to the lesson planning. These moments are significant as how teachers notice and decide to act in these moments may determine the quality of instruction. The analyses of lesson planning meetings, lesson observations and interviews with the teacher revealed only three cases of unexpected moments as she taught algebra. The results indicated that unexpected moments of teaching in the form of student questions and responses helped the teacher reflect for future lessons. The instructional actions during these moments had the potential to support and extend student thinking.*

*Keywords: Instructional actions, student thinking, teacher noticing, pivotal moments in teaching.*

## Introduction

Teaching practices play a significant role in shaping student learning (Franke, Kazemi, & Battey, 2007). Research studies (Franke et al., 2007; Hiebert & Grouws, 2007) underline the importance of teachers choosing and implementing high-cognitive demand tasks and shaping meaningful mathematical discussions. Teachers are expected to support their students in achieving learning goals, pay attention to students' knowledge and motivation, and adjust instruction accordingly (Ball, Lubienski, & Mewborn, 2001; National Research Council [NRC], 2005). This type of student-centered instruction demands that teachers not only teach the curriculum as given but change it by taking into account their students' needs during the moment of instruction.

In general, previous studies (Fenenma & Franke, 1992) and reform documents (National Council of Teachers of Mathematics [NCTM], 2000) indicate the importance of planning in order to create meaningful mathematical discussions in student-centered instruction. When teachers use research-based protocols and consider students' prior knowledge in preparing a lesson plan, they may be able to incorporate student thinking in better ways (Smith, Bill, & Hughes, 2008). Adjusting lesson plans according to student needs and building meaningful discussions are important skills generally attributed to more experienced and highly-accomplished teachers (Taylan, 2015).

Although the relationship between the nature of mathematical discussions and student learning is complex, it is documented that some teacher instructional actions during classroom discussion may have more potential than others to advance or extend student thinking. In a framework developed by Cengiz, Kline and Grant (2011), *inviting students to evaluate a claim and provide reasoning and probing, challenging and providing counter arguments to student claims and pushing for alternative ways* were categorized as instructional actions that extended student thinking during

class discussions. Actions that supported student thinking involved *repeating a student idea*, *suggesting interpretation of student thinking*, *introducing different representations*, *reminding of the learning goal*, and *recording and acknowledging student thinking* (Cengiz et al., 2011). *Complimenting or evaluating student thinking*, *redirecting to peers*, *requesting basic information* and *clarifying questions* were actions that were classified as other actions which did not support or extend student thinking. Managing discussions by considering the influence of different actions as described in research-based frameworks may help teachers in supporting and extending student thinking in more productive ways.

Consideration of potential student responses to tasks helps teachers in responding to their students' needs in-the-moment of teaching during classroom discussions, but it may not be enough to advance students' mathematical thinking. In fact, Rowland, Thwaites and Jared (2015) defined contingency as part of necessary teacher knowledge which helped teachers face unexpected moments when they had to deviate from their plans during teaching. Teachers need to pay attention to both development of mathematical concepts and student ideas that come up spontaneously during discussion (Sherin, 2002). Stockero and Van Zoest (2013) defined pivotal teaching moment (PTM) as moments when teachers notice and act upon those moments and change the flow of the instruction according to students' thinking, i.e., students' unexpected comments and questions, misconceptions, or confusions. During these unexpected circumstances teachers may choose to ignore the PTMs or build upon them to extend the lesson that they planned before. In this study, the focus of inquiry was a novice teacher's instructional actions during unexpected moments of teaching by taking into account her planning and reflections on teaching. Understanding planning and teacher decision-making processes has a potential to contribute to both research in teacher professional development and actions involving student-centered teaching, as little is known about how to act productively in such situations.

## Method

This is a case study (Yin, 2003) of a novice mathematics teacher. The authors explore instructional actions of the teacher during unexpected moments of teaching using qualitative methods.

## Participants

The participant teacher held a master's degree from a highly selective teaching program in Turkey. She had two years of teaching experience in middle school. The school where she taught was a private school in Istanbul, Turkey and teachers were supported and encouraged to prepare detailed lesson plans collaboratively. The participant teacher's lessons and planning meetings were observed by one of the authors. The participating teacher was selected due to her experience in developing detailed lesson plans both as a teacher candidate and as a teacher.

## Research Tools

Research tools included semi-structured interviews with the teacher, observations of mathematics lessons and recordings of lesson planning meetings. Planning meetings were conducted with the participating teacher and other mathematics teachers who taught 6<sup>th</sup> grade in the same school. During observations of three planning meetings, algebra lessons were planned by a group of

teachers teaching 6<sup>th</sup> grade in the school. All three meetings were observed and transcribed. Planning meeting transcriptions were useful to understand how teachers planned to create mathematical discussion environment and designed the lessons.

The interviews which took place both before and after observations provided opportunities to understand the teacher's perspective and her decisions about creating mathematical discussion environments in the class and how classroom talk could lead to student understanding. The interviews before classroom observations were about the teacher's thoughts on planning and anticipation of teaching decisions, for instance exploring the questions that the teacher planned to ask. The interviews after classroom observations allowed the authors to ask the teacher to reflect on how the lesson went and discuss her decision-making process as well as student learning. During these interviews, the teacher was asked to reflect on what went well or what she would change for the next lesson based on the experience. The teacher also had a chance to express what caught her attention and whether she made a decision to change the lesson plan due to unexpected moments. The interviews which lasted about half an hour took place both before and right after each lesson observation.

Overall, there were five lesson observations, five interviews before the observations and five interviews after the observations with the teacher. Additionally, there were observations of three lesson planning meetings and one general interview with the teacher in order to gain insights into her beliefs and perspectives as a mathematics teacher which helps us understand her actions in better ways. Beliefs are inherently related to instructional actions. Data collection took place over three weeks when the participating teacher taught algebra in the 6<sup>th</sup> grade. The second author observed both planning meetings and the mathematics lessons as a participant observer. Five lessons in algebra were observed. Classroom talk during each lesson was recorded and transcribed. Attending planning meetings, observations of the lessons and conducting pre-and post-observation interviews allowed researchers gain insights about the complexities involved in teacher decision making during the unexpected moments in teaching and details of the lesson flow.

## **Data Analysis**

During the data collection and across five lesson observations three unexpected moments of teaching were observed. The unexpected moments were selected because they happened as a result of interaction with students, which were not anticipated in the planning meetings. An example of these moments was unanticipated student difficulty that was not discussed during the planning meetings. These moments were also confirmed with the teacher as unexpected during the interviews which took place after the lessons. To analyze the instructional actions during those unexpected moments, classroom talk during the unexpected moments were transcribed and teacher's actions were classified according to a framework developed by Cengiz et al. (2011).

## **Results**

According to the analyses of lesson planning meetings, classroom observation transcripts and interviews before and after observations, three unexpected teaching moments were revealed. Unexpected answers, comments and questions in relation to teacher and student learning are provided in the next sections.

Several episodes of teacher instructional actions and her reflections in the context of responding to students' unexpected answers, comments and questions were discussed by taking into account of constructs of teacher noticing and pivotal teaching moments. Analysis of transcripts using the instructional actions framework (Cengiz et al., 2011) revealed that teacher instructional actions included supporting and extending actions. More specifically, *recording and acknowledging student thinking* and *inviting students to evaluate a claim, challenging/providing counter arguments to student claims* were observed as the teacher responded to changes in the lesson flow. Considering students' engagement and answers in the discussion, it may be argued that teacher was able to create a rich discussion environment by demonstrating such instructional actions.

## Unexpected Moments of Teaching-1

The first unexpected moment was identified in the introductory lesson to the algebra concept. The lesson plan associated with this topic involved "the birthday magic activity" which was a number guessing game. This was the first time the 6<sup>th</sup> grade students were going to hear about the topic of algebra. Students were expected to engage with this activity, use four operations using their birthdays and come up with a number. At the end of the activity, the teacher planned to guess students' birthdays and explain that the use of algebra was needed in order to perform this magic. The teacher aimed to motivate students for learning algebra.

During the planning meeting, the teachers decided to provide the following instructions for the students about the birthday magic activity:

Start with the birthday month (if your birthday month is October, you will start with 10). Multiply this number by 5. Add 7 to the result. Then multiply this result by 4 and add 13. Multiply the result by 5 and add the birthday date (First lesson plan).

The teacher planned to subtract 205 from the resulting student answer and guess students' birthdays. The teacher anticipated that students would understand the pattern of the birthday magic activity after several examples.

In the following episode, the first unexpected moment occurred when a student used a different strategy than what the teacher thought before lesson. Below is the transcript of student answer and teacher response when a student was trying to guess a peer's birthday:

Student: I found the answer like this. I was born on the 25<sup>th</sup> of January and the result was 330. When my friend said 328, I went back two days, my friend must be born on the 23<sup>rd</sup> of January.

Teacher: Well, you found like that, by using a clue. What if the number associated with your friend's birthday was not close to yours? How would you find it then, if you did not have a clue?

Although the teacher acknowledged the student answer in the above episode, she also challenged this answer and pushed the student to find alternative ways so that the answer would not be relevant in only specific circumstances. The instructional actions occurred during this lesson were requesting basic information, clarifying questions, complimenting and evaluating, challenging/providing

counter arguments to student claims, pushing for alternative ways, inviting students to provide reasoning and probing (Cengiz et al., 2011).

In the same introductory lesson, there was another unexpected moment. Before the lesson, the teacher expected the resulting number she would get from students to be 4 digits. However, during the activity, some students provided three digit answers. The teacher had a difficulty in deciding which two digits of student answers were birth month or birth day. Additionally, some students made calculation mistakes in producing their birthday number, which resulted in inaccurate guesses. Here is what teacher said about how the lesson went according to plan:

Teacher: Actually, we did not think of using calculator but if student made calculations incorrectly then the activity does not work. Now, our learning outcome is not addition or subtraction. That's why we (the group of 6<sup>th</sup> grade teachers) decided to use calculator as a last-minute decision. That's why actually my plan changed. I made a strategy like first subtract 200 and then 5. Later I thought I can also use tablet and it would be faster. During the activity, I was sure about one student's birthday but the answer was wrong. After that I was confused because while we were studying we always went through 4 digits. When students said 3 digits, I couldn't decide what the birthday would be: the first two digits or last two digits. Maybe I should have practiced more on my own (Post-lesson interview after the first lesson).

As observed in the above transcript, the teacher attributed the unexpected moments in teaching to not being well prepared and anticipating different patterns. Although the teacher was going to ask a few students' birthdays in the plan, she asked all students with the unexpected confusion. As a result of this unexpected moment, the teacher reflected for future lessons and thought about how to prepare better and anticipate student answers in more productive ways.

## Unexpected Moments of Teaching- 2

During this lesson students practiced operations with algebraic expressions. This unexpected teaching moment occurred when a student asked an unexpected question about writing an algebraic expression. In one of the questions, the students found an answer in the form of:  $1+y/7$ . After that the following conversation took place between the teacher and a student:

Student: Can we add them ( $1+y/7$ )?

Teacher: Can we add them? Are those similar terms?

Student: Teacher, but can't we write 1 as whole part?

Teacher: Hmm. Do you mean like this, "1 whole  $y/7$ " as in fractions?

Student: Yes.

Teacher: Yes, you can. Like this (Teacher wrote the answer on the board.)

Student: Yes.

Teacher: I'm thinking. You can. Nice. Are there any questions? Are you sure?

In this lesson, the unexpected moment didn't change the flow of the lesson. Teacher clarified the meaning of what the student suggested and acknowledged the student answer. The teacher also recorded the answer on the board and shared it with class. The instructional actions were complimenting, requesting basic information, repeating student idea, claim, question, recording student thinking. In this specific unexpected moment, the teacher challenged the student answer in the beginning ("Are those similar terms?") but later accepted what the student meant. The student made a connection with the concept of fractions. However, the teacher did not invite other students to evaluate the claim and make the discussion public. During the post lesson interview, the teacher said she was not expecting this connection with prior topics and she was pleasantly surprised. Although the teacher's aim was to create a discussion environment, in this unexpected moment there was a lost opportunity to create a pivotal moment of teaching to make student thinking public, which could help other students make similar connections.

### Unexpected Moments of Teaching- 3

The last unexpected moment was identified during the lesson about patterns and algebra. The teacher asked students to give a number pattern. The unexpected teaching moment occurred when a student posed a question that the teacher had not considered prior to the lesson.

Student: Teacher, can we make it like this? (i.e. "a pattern like this?")

Teacher: Say it.

Student:  $1x, 2x, 3y, 1x, 2x, 3y$

Other students are giving similar examples, they discuss constructing different patterns by using numbers instead of  $x$  and  $y$ 's. In this moment, the whole class was involved.

Teacher: Let's write,  $x, 2x, 3y, x, 2x, 3y$ . Is this a pattern? (directing this question to the whole class, inviting other students to the discussion)

Students were engaged and providing different answers. Some provided the right answer and some were not sure about the answer.

Teacher:  $x, 2x, 3y$  is a pattern. To understand that it is a pattern we want to see that it is repeating. There are variables but are they repeating with a rule, that is the important point.

Later during the interview, the teacher revealed that she did not expect this question. During this moment the teacher had a choice to ignore the student question or just acknowledge it and continue. Instead, she chose to make the discussion public and have other students participate in the discussion. The teacher changed the flow of the lesson for a few minutes based on a student response and spared time for discussion.

Teacher: I like it when students ask something beyond expected, they (students) can be so creative and such responses make classroom discussion become richer (the last interview).

The instructional actions during this unexpected moment were found as requesting basic information, repeating student idea, claim, question, acknowledging student thinking, recording student thinking, reminding of the goal, suggesting an interpretation, inviting students to evaluate a claim, and challenging/providing counter arguments to student claims.

## Discussion

Results of data analyses revealed only three unexpected moments of teaching. In general, the planning sessions were very detailed and planning discussions among teachers encouraged them to think of potential student answers, weaknesses and strengths. There were not many unexpected moments for the teacher probably because she participated in collaborative and detailed planning sessions together with experienced teachers. Considering three unexpected moments of teaching, not all were pivotal teaching moments for the classroom, i.e., they did not allow for extended understanding among all students. There may be several reasons as to why this happened. For the first unexpected moment, the teacher had a difficulty because it was the first time she tried to play a guessing game with students but there were some answers that she did not anticipate. For the second unexpected moment, the teacher did not ignore the unexpected student question but did not make the student question public or invite other students to evaluate the claim. In contrast to the first two unexpected moments, during the third unexpected moment the teacher made the unexpected question public in the classroom and initiated classroom discussion.

The beginning teacher in this study considered how she could teach the next lesson in a better way with experience of unexpected moments of teaching. Experiencing unexpected moments appeared to have the potential to help the teacher's professional growth and planning for richer discussions for the next cycle of teaching similar concepts. This phenomenon was also mentioned by Smith et al. (2008). Analysis of instructional actions during unexpected moments revealed that the teacher demonstrated similar actions in different cases. Future research may utilize different frameworks in analyzing teacher actions. The analysis of instructional actions did not seem to predict quality of discussion on its own, which may need to be supported by other frameworks in future studies. This was a case of a novice teacher who was motivated to build instruction by considering student thinking. Analysis of the interviews and observations indicated that the teacher valued different types of student thinking and explored student thinking by asking open-ended questions and initiating classroom discussions. The instructional actions included types of actions that had potential for supporting and extending student thinking (Cengiz et al., 2011; Taylan, 2015). These findings are in contrast with previous research which documented beginning teachers mostly focused on classroom management and on their experience as beginner teachers (Schmidt, Klusmann, Lüdtke, Möller, & Kunter, 2017). The teacher in this study was in a high-achieving school and did not have many classroom management problems, which helped her build meaningful classroom discussion environments. Our study revealed detailed planning and teacher collaboration culture and as well as individual experiences and motivation seemed to help this teacher in creating and managing mathematical discussions.

## Feedback for creative reasoning

Anna Teledahl<sup>1</sup> and Jan Olsson<sup>2</sup>

<sup>1</sup>Örebro University, School of Science and Technology, Örebro, Sweden; [anna.teledahl@oru.se](mailto:anna.teledahl@oru.se)

<sup>2</sup>University of Mälardalen, Department of Education, Culture and Communication, Västerås, Sweden; [jan.olsson@mdh.se](mailto:jan.olsson@mdh.se)

*This study investigates how principles of feedback to encourage students' creative reasoning can be used by a mathematics teacher. An experienced teacher was introduced to principles, developed in pilot studies, and was instructed to plan a lesson based on four principles for feedback. During the lesson the teacher's interactions with students were recorded and the following analysis focused on the way feedback resonated with the principles. The result indicates that providing feedback which challenges students to reason creatively is difficult and complex. There are pitfalls that originate in established classroom norms for interaction, as well as beliefs about the object of teaching, and it appears that the principles, in order to become a powerful tool, require the teacher and students, to practice using them.*

*Keywords: Instructional design, teaching methods, feedback.*

### Introduction

Students, who are encouraged to construct their own solutions and create arguments when solving mathematical tasks, tend to, if they are successful, learn or remember more from such activities than students who are being guided by templates and prepared examples (Jonsson, Norqvist, Liljekvist, & Lithner, 2014). Despite the disadvantages, described in numerous research reports, of teaching mathematics by providing solution methods to tasks, such teaching is still prevalent in many classrooms, in Sweden, as well as around the world (Boesen, Lithner, & Palm, 2010; Hiebert & Grouws, 2007). Teaching where students create and justify their own solutions (i.e., engaging in creative reasoning) requires different teacher-student interactions than traditional teaching. Rather than explaining which method to use as well as how and why it works the teacher must encourage students, not only to construct own solutions, but also to challenge them to justify their choice of method (Hmelo-Silver, Duncan, & Chinn, 2007).

A teacher-student interaction aimed at supporting students' construction of solutions can be compared to feedback aimed at supporting the students' learning processes and thus relies on the active involvement of the student (Hattie & Timperley, 2007; Nicol & Macfarlane-Dick, 2006). Research on formative assessment and feedback often reports general guidelines on how to provide feedback in teaching but few studies present empirical results detailing how feedback can be prepared and designed in classroom situations (Hattie, 2012; Palm, Andersson, Boström, & Vingsle, 2017). Hence there is need for a deeper understanding of how formative assessment/feedback can be implemented at a classroom level (Hirsch & Lindberg, 2015). As a preparation for this study a series of four pilot studies, involving mathematical problem solving, was conducted. The interaction between students and their teacher was studied with the aim of identifying what characterizes the kind of feedback that leads students to reason creatively. The findings can be interpreted as four basic principles: (1) find out how the students are thinking, demand that students are specific, (2)

encourage the students to formulate their thinking without interrupting or interpreting, (3) challenge the students to explain why their solution is working (or not working) – instead of confirming or disconfirming, and (4) encourage the students to find a way to test their solution. The present study investigates how the principles can be used by a teacher who is unfamiliar with them. Our aim is to refine the principles and to form guidelines for formative feedback that teachers can use to foster creative reasoning.

## Background

Teaching that encourages students to construct and justify solutions to mathematical tasks entails a focus on reasoning. Furthermore, it is reasonable to assume that teachers' feedback may guide the character of students' reasoning. The following paragraphs will outline distinctions between different types of reasoning and feedback relevant for the didactic design addressed in this paper.

### Imitative and creative reasoning

If the teacher explains a definition of a mathematical concept and then demonstrates how to solve tasks associated with this particular concept, it is possible for students to solve similar tasks by remembering the procedure without understanding the definition. Lithner (2008) found that students trying to apply memorized procedures often had difficulties when solving tasks for which there had been no recent teaching. For example, calculating  $2^3 + 2^4$  using a memorized process could mean mixing up whether the numbers should be added or multiplied. The reasoning associated with such an approach is defined as imitative (IR) (Lithner, 2008). A variant of IR is AR, algorithmic reasoning which is relevant for this paper. AR entails recalling a memorized, stepwise, procedure or following procedural instructions from a teacher or textbook, that are supposed to solve a task (Lithner, 2008). AR is algorithmic in the sense that it solves the associated task, but it does not require an understanding of the mathematics on which the procedure is based.

An alternative approach to the example above,  $2^3 + 2^4$ , may be to consider what the mathematical meaning behind the expression is, i.e.,  $2^3$  means  $2 + 2 + 2$ , and  $2^4$  means  $2 + 2 + 2 + 2$ . After realizing this, the next step is to put the two together,  $2 + 2 + 2 + 2 + 2 + 2 + 2 + 2$ , which is  $2^7$ . If the student can express mathematical arguments for the solution she is engaged in creative mathematical reasoning (CMR). CMR is characterized by the construction or reconstruction of a solution method and the expressing of arguments for the solution method and the solution (Lithner, 2008).

### Feedback

It is possible for students to reach correct answers to tasks without understanding the mathematical concepts involved (Brousseau, 1997). If a student should fail in his or her attempts to solve a mathematical task, the most obvious feedback from the teacher may be an explanation regarding how to solve the task, not to explain the mathematics it is based on. Should the student, however, be responsible for the construction of the solution method, she is helped by understanding the mathematics required by the task. In such cases, it is appropriate for the teacher to inquire into the student's thinking. Inquiring into students' thinking can be seen as part of formative feedback at the process level whereas delivering or assessing a right or wrong answer is seen as task level feedback

(Hattie & Timperley, 2007). Research indicates that 90 % of feedback in classrooms is on task-level (Airasian, 1997). Feedback on process-level focuses on the underlying mathematical processes, which can support students' conceptual understanding as well as their autonomy (Kazemi & Stipek, 2001). This type of feedback creates interactions in which students have an opportunity to develop their ability to use mathematical ideas to formulate arguments and justifications for their choices (Michaels, O'Connor, & Resnick, 2008).

### **Development of principles for feedback aimed at supporting creative reasoning**

The principles for feedback were developed iteratively during a year in four pilot studies in collaboration with a teacher (see Olsson & Teledahl, 2018). The starting point for the pilot studies was the design of appropriate tasks for CMR. Then possible solutions to the tasks, together with the potential difficulties that students will encounter, were considered. For each of these solutions and difficulties feedback aimed at supporting CMR was designed. The lessons were recorded and the interactions between the teacher and the students were analyzed with the aim of identifying the characteristics of the feedback that led students to reason creatively. The result of every analysis was used in the planning of the next lesson. After the fourth intervention, principles for feedback supporting CMR were formulated. These principles (see Introduction) were used in the present study to support the design of the intervention (to setup student activities where feedback for CMR is appropriate) and to prepare the teacher to formulate feedback for CMR.

### **Method**

In order to test the previously developed principles for feedback a new study was set up in which a lesson was planned so that students would have the opportunity to engage in CMR. The principles were also used to prepare the teacher and help him support students' CMR through feedback. During the lessons the teacher's interactions with students were recorded. Compared to other possibilities (e.g., interviews) data was considered to be reasonably close to the thinking processes that create feedback and reasoning. Feedback is considered as both a response to students' actions and guiding their continued reasoning. The chain students' action – teacher's feedback – students' continued reasoning was the unit of analysis.

### **Sample**

A teacher and students in 8<sup>th</sup> grade of a Swedish elementary school volunteered to participate. The teacher is experienced in teaching mathematics through problem solving and the students were used to problem-solving activities. The teacher did not participate in the pilot studies where the principles for feedback were developed. Instead, he was introduced, during a half-day seminar, to the idea of supporting students' CMR through feedback according to the principles. Transcripts from the pilot studies were discussed and tasks suitable for the class participating in this study were considered. The teacher considered the class to be average in terms of achievement, and a mix of students with Swedish as their native or second language. With respect to feedback, in his everyday teaching, the teacher considered it his intention not to guide students to solutions, although he did not have explicit strategies for achieving this. Neither the lesson, nor the feedback, would thus be considered something out of the ordinary and according to the teacher, the interactions were typical for his style of teaching.

## Lesson plan

The teacher was instructed to plan a lesson containing problem solving. The role of the teacher was to support students in constructing solutions rather than explaining how to solve the problems. It was assumed that successfully constructing solutions, without knowing a solution method in advance, would require students to engage in CMR. The tasks were designed in line with Lithner's (2017) principles: (1) creative challenge, no solution methods are available from the start and it must be reasonable for the students to construct the solution, (2) fair conceptual challenge to understand mathematical properties (e.g., representations and connections) and (3) justification challenge, is it reasonable for the particular student to justify the construction and implementation of a solution. The tasks were part of the curriculum and involved combinatorics. *Task 1a* asks the students to find all of the different ways to put three blocks of different colors in a row. The students were supplied with concrete materials. In *task 1b* another block, of yet another color, is added. The teacher was also instructed to prepare to give feedback according to the principles.

## Procedure

During the lesson, the students worked in pairs. The tasks were presented in written text and the students were asked to present written solutions. The students were encouraged to collaborate and call the teacher if they did not understand the instructions, or if they got stuck. The teacher was wearing a recording device, which recorded his interactions with students. The recordings were transcribed into written text, with a focus on spoken language.

## Analysis method

The analysis focused on the chain students' action – teacher's feedback – students' reasoning in connection teacher's feedback, and was performed through the following steps:

(I). Parts of transcripts where the teacher interacts with students, and where it is considered possible to provide feedback according to the principles, were identified. (II). Parts of transcripts, where the teacher's feedback resonates with the principles for feedback, were identified. (III). It was determined whether feedback, according to the principles, supported or did not support students' CMR. (IV). In interactions, where the principles were not implemented consistently or only partly implemented, possible trajectories leading to CMR were considered and the way the principles could have supported CMR was analyzed.

The analysis was a joint effort that involved the teacher.

## Results

The lesson was conducted according to plan in the sense that students got engaged in problem solving where they did not have access to a solution method for the tasks. Interactions with the teacher could be observed when a solution to a task was reached or when students asked for help. We will now present two extracts from the transcripts which can be seen as examples of interaction where the teacher can be considered to have possibilities to provide feedback according to the principles.

In the first example, which is representative of a number of interactions during the session, the student had come to a solution to *task 1a*:

1. Teacher: Explain the way you are thinking.... it looks like you have some system.
2. Student: Well.... if you start with a block.... for instance, a green one.... you can always change the order of the other two blocks.... and in this case, there are three blocks.... so, you have plus two combinations.... so, in this case it can be green-white-yellow and green-yellow-white.... so, if we have three blocks it will be three times two.
3. Teacher: OK.... you can go on to the next task

The teacher asks the student to explain her thinking (line 1) which is in line with the first principle. While the student did not know how to solve the task in advance it is reasonable to assume that the answer (line 2) represents, at least partly, CMR (constructing a solution). As a whole only the first principle is used. The student is not articulating arguments explicitly, which could have been encouraged by first inviting her to express her understanding (principle 2) and then challenge her to explain why her method results in correct answer (principle 3). The last utterance in line 2, when the student suggests a way to calculate the numbers of combinations, can be used to challenge her to justify their solution (principle 4). The teacher's comment on line 3 does not correct the student, which gives her an opportunity to find out that although the calculation is correct in connection to *task 1a*, it will not work in *task 1b*. This is an example of when the teacher's decision to refrain from explaining, gives the student an opportunity to discover the error in her conclusion. In the next task (1b) the teacher has the opportunity to challenge the student's reasoning using principles 2-4.

The second excerpt was chosen as an example where principle 3 could have been appropriate. It introduces a similar situation as example 1 and indicates the importance of the formulation of feedback. A pair of students have come to a solution on task 1a and now call for help with task 1b.

1. Teacher: What did you conclude on task 1a?
2. Student: We conclude that for every color.... if it is situated in one place.... there are two combinations for where the others could be situated.... that goes for every color situated in each place.... but if you add one block there will be four blocks and there will be three combinations for each block in each position.
3. Teacher: Are you sure?
4. Student: No.... there will be more then.
5. Teacher: How many positions can this be in?
6. Student: Then it would be.... these ones.... ok.
7. Teacher: If there were three blocks they could be situated in....
8. Student: If they were three they can.... yes.
9. Teacher: This was the prior task [1a].... wasn't it?
10. Student: Then there will be six ways for these.
11. Teacher: Yes.... if the blue one is first.... but you don't have to put the blue one first.
12. Student: No.
13. Teacher: So, how many could it be.... how many ways is it if the yellow is first?

14. Student: If the yellow is first there will be six ways.  
 15. Teacher: OK, so how many is it all together?  
 16. Student: Twenty four.  
 17. Teacher: OK.... could it be more ways.... are there any others that could be first?  
 18. Student: No, these are the only ones you can have first.

In the planning for feedback it was considered that the reasoning connected to 1b could be continued from the solution of 1a. Therefore, on line 1 the teacher focuses the feedback to the task 1a. The question posed in line 1 may be associated to principle 1. The student's reasoning on line 2 includes both how the solution is constructed and arguments which are components in CMR. The teacher's question on line 2 could have been in line with principle 3, but the student seems to perceive the question as an indication she is wrong. From here the teacher's feedback instead of following the principles is mainly on task-level, i.e., its purpose is to guide the students to a solution, not to support CMR. The student does not fulfil the CMR from line 2, instead, the reasoning turns into guided AR (imitating the teacher's reasoning).

### Summary of results

Mathematical reasoning is considered creative (CMR) if students themselves construct or reconstruct a solution method to a problem and express arguments to support this. The two examples above indicate that students, who are encouraged to explain their thinking, express CMR. Through their explanations it seems clear that they have constructed solutions to problems, for which they did not have access to a solution method in advance. Less clear is the way students formulate arguments for their solution. In neither of the examples are students encouraged to justify or articulate arguments. The principles for feedback in this study were developed to encourage students to construct their own solution methods and formulate mathematical support for their solutions. The results indicate that it may not be an easy task, even for experienced teachers, to implement these principles.

### Discussion

Creative reasoning is a powerful tool in the learning of mathematics. In mathematical problem-solving creative reasoning, where conjecturing and justifying are viewed as important parts, leads students to construct their own solutions to mathematical tasks, something that previous studies have found beneficial for their learning (Jonsson et al., 2014; Olsson & Teledahl, 2019). How to design teaching, in particular feedback, which will encourage students to construct solutions and present support for why they are correct, is still something that we know too little about.

Teaching where students are constructing solutions while engaging in CMR does not entail a passive teacher (Hmelo-Silver et al., 2007). The teacher in this study planned the activities with the intention of creating situations where feedback, in line with the principles, would be appropriate. In the first excerpt, the students have managed to solve task 1a and principle 1 is used to challenge the students to articulate their reasoning explicitly. After the students have explained their thinking, the teacher without verifying the students' solution, encouraged them to move on to task 1b. By not confirming or disconfirming the solution to the first part of the task the teacher creates an opportunity for the students to discover that their method for solving in 1a will not work in 1b. He

does not challenge them to explain anything, or ask them why they think it works, but rather leaves them to test their solution in the next stage. He is thus creating an opportunity for the students to continue their CMR, and for himself to challenge the students to formulate arguments for their solution, at a later stage when they, hopefully, have made useful discoveries about their original idea. This situation leads us to realize that the teacher not only has to consider the principles for *how* to challenge students to explain and provide argument but also *when* to do so. In this interaction giving students time and space might lead them to insights that helps them to argue for their final solution. It might be challenging to teachers to be consistent in constantly providing feedback, according to the principles, but also to retain a sensitivity to when it may be a good idea to leave the students alone.

Example 2 shows, what may be an even greater challenge, to avoid explaining how to solve a task when students ask for help. Again, principle 1 seems to work well. Students express their reasoning and leave space for feedback in line with principles 2, 3, and 4. Here, the teacher may have in mind not to explain the way to solve the task, but instead of asking the students to explain he uses questions that, step by step, guides the students towards a solution. On the surface, it might seem like he is sticking to the principles, given that he is using questions instead of statements and hints, but the questions can be seen as a way to implicitly provide the solution. The responsibility for the mathematical reasoning shifts to the teacher and the students miss an opportunity not only to develop their ability to provide mathematical arguments but also to retain their autonomy (Kazemi & Stipek, 2001; Michaels, O'Connor, & Resnick, 2008). It may be tempting for the teacher to explain or to guide the students to a solution, not only because it saves time when the teachers is stressed, but also because it produces a result, a solution. In this way the product, rather than the process, becomes the main object. A solution to a problem, even if it was obtained by imitating the teacher (AR according to Lithner, 2008) is considered more valuable than CMR, which may not even result in a complete solution. To focus feedback on the underlying thinking process that will solve the task is most likely difficult and it places high demands on both teachers and students.

Since the collaborative teacher in the pilot studies was involved in developing the principles for feedback she became gradually aware of how to use them and what they would lead to. In addition, while she was positive to the idea of students learning through CMR, she also practiced using the principles between the four interventions, which were planned in collaboration with the authors. The teacher, who participated in the current study, was also positive to teaching according to the principles. The difference was that he was introduced to the concept through a few hours of instructions. The two examples of interaction, shown above, highlight how important it is to carefully formulate your questions. In every classroom there is an established pattern for teacher-student interaction, and in order for such patterns to develop towards CMR teachers and students need, not only to practice using the guidelines, but also to reflect on their current patterns of interaction.

# Revisiting teacher decision making in the mathematics classroom: a multidisciplinary approach

Steven Watson<sup>1</sup>

<sup>1</sup>University of Cambridge, Faculty of Education, UK; [sw10014@cam.ac.uk](mailto:sw10014@cam.ac.uk)

*The purpose of this paper is to consider the role of mathematics teachers' thinking and decision making in the classroom. This has been a somewhat neglected area of research since the mid-1980s, but I will argue here that understanding the nature of teachers' thinking and decision making in lessons is important in understanding practice and can inform approaches to initial teacher education and professional development. While mathematics teachers' knowledge and beliefs are important, the decisions they make and the actions they implement in the lesson influence the learning environment, culture and interpretation of tasks and activities. I draw on my own empirical research along with a multidisciplinary account based on developments in cognitive psychology, neuroscience and ontology (e.g., posthumanism) to provide a theoretical account of teacher thinking and decision making and how this influences practice.*

**Keywords:** Teachers' decision making, teaching practices, teaching methods, teachers' knowledge, teachers' beliefs.

There was considerable research into teachers' thinking and decision making during the 1970s and 1980s, but since the mid-1980s this was rather displaced by a surge of interest in teachers' knowledge (Borko, Roberts, & Shavelson, 2008). It is not entirely clear why there was a change in direction, but it is likely that the seminal American Educational Research Association presidential speech by Lee Shulman in 1986 heralded widespread interest in teachers' pedagogic content knowledge (Shulman, 1986). Since then researchers have been more interested in what teachers know in terms of discipline-based pedagogical knowledge than they have been in teachers' thinking. This is not to say, of course, there have been no recent contributions to the field of teacher decision making. Notably, Alan Schoenfeld's book *How We Think* (2011) directly addresses teacher decision making and thinking in the classroom and builds on the earlier research. But there remains further opportunity to revisit and extend the existing research using recent thinking from neuroscience and psychology. My aim here is to argue why, while acknowledging the important contribution of research into teachers' knowledge and beliefs, research into teacher thinking is necessary in order to gain a better understanding of the nature of classroom practice.

The background to this is mine and colleagues' recent research (Watson, Kimber, Major, & Marschall, 2018) into how teachers implement ambitious teaching approaches (Stylianides & Stylianides, 2014) in post-16 (A Level) mathematics classrooms. An intense idiographic inquiry led us to consider how teachers make decisions in the classroom and the nature of the underlying thinking and reasoning processes. We found we could not easily explain, like many researchers before us, why even in the context of supported teaching reforms, a teacher almost naturally tends to a traditional teacher-centred approach in the classroom. And when the teacher is encouraged and supported in implementing ambitious teaching and in giving mathematical authority/authorship (Povey & Burton, 1999) to the students they seem compelled to retain authority/authorship. This is not by any means a

criticism of teachers, but it is undoubtedly a phenomenon that warrants exploration and a search for further understanding. Our research, building on past research into teacher thinking and recent developments in cognitive psychology, neuroscience and ontological accounts such as posthumanism, suggests that in-the-moment decision making (Schoenfeld, 2011) in the classroom has an important role in this.

It is first necessary to distinguish between teachers' thinking in the lesson as they interact with students and the thinking and decision making that takes place in the planning of and reflecting on lessons. I adopt here the following categorization of teacher thinking developed by Clark and Peterson (1986):

- Teacher planning (preactive and postactive thought);
- Teacher interactive thoughts and decisions;
- Teacher theories and beliefs.

There are qualitative differences between the decisions made in the moment in the lesson and the teacher's thinking about the lesson before and after the lesson. Decisions in the classroom have to be made quickly in a complex and demanding environment. But both interactive, in-the-moment decisions and planning are underscored by a teacher's theories, knowledge and beliefs. The knowledge and perspectives in memory provide the resources that contribute to reasoning processes. The turn to pedagogic content knowledge in the late 1980s tends to privilege the role of teachers' theories and beliefs, I argue here (and following our empirical research) it is the momentary decisions that influence the character of the lesson. That is, in-the-moment decisions can lead to a lesson becoming more traditional and teacher-centred even though the teacher may have the knowledge of and hold beliefs in reform-oriented student-centred approaches (or 'ambitious' teaching)<sup>1</sup>.

Traditional teacher-centred teaching typically involves teacher exposition or demonstration followed by student practice on routine graduated exercises and might conclude with a whole-class review. In contrast, student-centred<sup>2</sup> practice involves students in collaborative dialogic problem-solving, inquiry-based or investigative activities in which they construct meaning and conceptual understanding (or 'relational' rather than 'procedural' understanding, see, Skemp, 1976) where the mathematical authority and authorship (Povey & Burton, 1999) is transferred to students. This has been given a catch-all characterization of 'ambitious' teaching (Stylianides & Stylianides, 2014).

From the perspective of cognitive psychology, human reasoning and decision making are characterized as either unconscious and intuitive Type 1 processes or rational and conscious deliberative Type 2 processes (Evans & Stanovich, 2013). Intuitive unconscious reasoning is rapid

---

<sup>1</sup> The implicit assumption here is that the traditional teacher-centred teaching is a default and largely prevalent approach to practice – this is certainly underpinned by evidence from the Office for Standards in Education (Ofsted) in England (Ofsted, 2008, 2012). I contend this to be a justifiable claim for high school and secondary mathematics teaching practice in Europe and the US (see, for example, Cuban, 1993; Stigler & Hiebert, 1999).

<sup>2</sup> The characterisation of traditional teacher-centred practice and student-centred practice draws on Larry Cuban's historical analysis of classrooms in the USA (Cuban, 1993).

and is employed in complex and demanding situations where decisions have to be made quickly (Johnson-Laird, 2006). Conscious reasoning uses working memory to construct mental models and assess possibilities prior to making a decision and taking action. Research into teacher decision making in the 1970s and 1980s acknowledged the distinction between unconscious (Type 1) and conscious (Type 2) reasoning and recognized that classroom demands require intuitive Type 1 decisions (Clark & Peterson, 1986; Shavelson & Stern, 1981). At the same time, Clark and Peterson recognized deliberative aspects of teachers' interactive decision making in the classroom. Shavelson and Stern (1981) suggested teachers draw on existing routines and sub-routines to simplify their interactive decision making.

...teachers' interactive teaching may be characterized as carrying out well-established routines. In carrying out the routine, the teacher monitors the classroom, seeking cues, such as student participation, for determining whether the routine is proceeding as planned. This monitoring is probably automatic as long as the cues are within an acceptable tolerance. However, if the teacher judges the cue to be outside tolerance (e.g., student out-of-seat behavior during discussion), the teacher has to decide if immediate action is called for. If so, the teacher has to decide if a routine is available for handling the problem. The teacher may take action based on a routine developed from previous experiences (Shavelson & Stern, 1981, p. 483).

This implies a heuristic approach to decision making that is not entirely intuitive and involves conscious decisions using rehearsed actions and pedagogic routines. The nature of teacher decision making is somewhere between Type 1 and Type 2 reasoning.

Recent research on human reasoning goes beyond a Type 1 and Type 2 dichotomy and offers an intermediate type of reasoning. Stanovich, West and Toplak (2011) propose an algorithmic system. This is a Type 2 conscious process but makes use of heuristics and preestablished routines and processes to reduce the demand on working memory. Algorithmic reasoning draws on knowledge which is "...tightly compiled due to overlearning and practice" (Stanovich et al., 2011, p. 107) and is based on social and cultural knowledge acquired through participation (Stanovich et al., 2011).

In our research (Watson et al., 2018), most of the decision making in the classroom was based on algorithmic reasoning. For example, during the lesson we observed the teacher deciding to stop the class and explain a specific aspect of the mathematics to the whole class. He explained in a stimulated recall interview later that he made the decision to take this action during the lesson. He said that he felt that there were enough student misunderstandings to warrant some remedial action. This heuristic, he said, was learnt during his initial teacher education programme. He explained how he observed that if a teacher found that there were three or more students with a similar question, then it could be assumed that more students were likely to have the same difficulty, then they would stop the class and offer an explanation to the whole class. Based on his explanation of this vicarious learning process, it appeared likely that this heuristic had been supported with some justification from a mentor or experienced teacher. This is an example of algorithmic reasoning, it is a simplified (and almost intuitive) judgement of the situation and the retrieval of rules, procedures and strategies (Stanovich et al., 2011).

Mathematics teaching and teaching more generally is replete with pedagogical routines and strategies. Indeed, Alexander's (2001) analysis of primary classrooms observed complex hierarchical and temporal systems of routines and rituals. Leinhardt characterizes teachers' knowledge as "...highly proceduralized and automatic and in which a highly efficient collection of heuristics exist for the solution of specific problems in teaching" (Leinhardt, 1988, p. 146).

As a secondary mathematics teacher, my own practice featured automated, proceduralized routines and heuristics. For example, I had a routine for teaching how to solve simultaneous equations. It was highly procedural, I would refer to it as a 'recipe'. And as an experienced mathematics teacher, I did not have to think, in the moment, about the pedagogical process in too much detail. I had learnt it from other teachers and used it on many occasions. If students were having difficulty solving simultaneous equations I could quickly stop the class and invoke this routine. I knew that if students were becoming anxious (and potentially disruptive) I could quickly and authoritatively provide this well-rehearsed explanation and give the students some routine practice questions, and this would provide reassurance and calm the situation.

It is widely acknowledged in the literature that a major preoccupation for all teachers is the management of the classroom and the management of student behaviour (Martin, Sass, & Schmitt, 2012). Shavelson and Stern explain the main aim of the teacher is to "maintain the flow of activity" (Shavelson & Stern, 1981, p. 484) and that decisions are made when there is an indication of a "potential problem or unexpected event" (p. 484). At these points teachers become "aware of reality" and their attention focuses on student behaviour (Shavelson & Stern, 1981). Therefore, what prompts a teacher to make an in-the-moment or interactive decision is strongly influenced by the affective system, that is the senses, the autonomic system and physiology. While Schoenfeld offers a highly rationalistic account of goal-oriented in-the-moment decision making based on his previous research on mathematical problem solving, he acknowledges the importance of affect. He advocates for future research in decision making to work toward a "rapprochement of the physiological and psychological" (Schoenfeld, 2011, p. 195).

Indeed, this *rapprochement* can be observed in posthuman accounts of practice and potentially provides a compelling interdisciplinary account of thought, experience, affect and behaviour in the context of classroom practice. A posthuman<sup>3</sup> critique of teacher thinking represent a departure from the Cartesian mind/body duality (Strom, 2015); posthumanism emphasizes the physical, the material, the experiential and the embodied nature of cognition (Braidotti, 2013). The posthuman classroom is not populated by discrete individuals but is "...an assemblage of multiple human and non-human elements that are all connected and work together to jointly produce teaching and learning activity" (Strom, Mills, Abrams, & Dacey, 2018, p. 144). A feeling or sensitivity to the environment is processed by the amygdala, which is reciprocally connected with the brain cortex and the thalamus. The amygdala is often associated with 'fight or flight' responses. Effectively it helps us decide

---

<sup>3</sup> Posthumanism is not a rejection of humanity but a counter to humanism, as an anthropocentric project and a challenge to Enlightenment rationality that privileges the mind as a conscious and rational system as the primary mechanism for solving individual and collective problems.

whether a response should be intuitive and reactive or conscious and deliberative. Importantly it draws on episodic memories which have affective and emotional signatures to quickly make sense of the situation (Markowitsch & Staniloiu, 2011). In contemporary liberal society human responses are much more nuanced than simply ‘fight or flight’: in any critical situation then the amygdala is involved in the following processes, do we have to react quickly or intuitively with deeply embedded culturally and evolutionarily compiled behaviours? Is there time to invoke socially learned and culturally embedded heuristics, strategies, routines and processes (the algorithmic mind)? Or is there time to reflect and construct and mentally evaluate alternative hypothetical courses of action and use logical processes? (see, for example, Janak & Tye, 2015; Markowitsch & Staniloiu, 2011; Pessoa, 2017; Phelps, 2006).

Much human behaviour is intuitive, we respond to the context with culturally and evolutionarily compiled behaviours, like, for example, the fight or flight response. Algorithmic responses are invoked where simple decisions and well-practised responses are required, and these have been the focus of the research I have referred to in this paper (Watson et al., 2018). Reflective Type 2 thinking might take place in the planning and evaluation of lessons, or in the work of research and scholarship, for example.

While it might be argued that the goal of teachers’ decisions is to optimize student learning (see Schoenfeld, 2011) and this might be possible in the planning and design of lessons, tasks and activities, in interactive decision making, in the classroom, decisions have to be more immediate. The primary aim, in the moment, is to manage the social situation, as Cuban observes:

... teachers have learned to ration their time and energy to cope with conflicting and multiple societal and political demands by using certain teaching practices that have proved over time to be simple, resilient, and efficient solutions in dealing with large numbers in a small space for extended periods of time (Cuban, 2009, pp. 10–11).

The algorithmic mind quickly accesses routines and procedures that are learnt through participation and provide well-rehearsed and culturally-embedded approaches to respond to situations in the classroom. The mainstay of these established cultural scripts (Stigler & Hiebert, 1999) correspond to traditional teacher-centred approaches. Moments of doubt, pressure and uncertainty in a classroom are likely to result in an almost automatic response with teacher-centred routines, as we found in our research (Watson et al., 2018). This shifts the mathematical authority/ authorship back to the teacher. Research into mathematics teachers’ beliefs has shown that there is frequently a misalignment between teachers’ espoused and enacted beliefs (Thompson, 1984; Wilson & Cooney, 2002), teachers may profess beliefs in reform-oriented student-centred ambitious teaching, yet their teaching is largely traditional and teacher-centred. Cuban refers to teacher-centred progressivism (Cuban, 2009), where there are many surface features of reform and student-centred practice but fundamentally the pedagogy is teacher-centred – the mathematical authority/ authorship remains with the teacher. The classic illustration of this is Cohen’s case of Mrs Oublier (Cohen, 1990). The difference between espoused and enacted beliefs, and the manifestation of teacher-centred progressivism can be explained by considering the momentary interactive decisions and algorithmic reasoning that leads

to teachers implementing culturally established and embedded teacher-centred routines and scripts, as Leinhardt (1988) observes:

[The] resistance to change on the part of the teacher should not be perceived as a form of stubborn ignorance or authoritarian rigidity but as a response to consistency of the total situation and a desire to continue to employ expert-like solutions (Leinhardt, 1988, p. 146).

The “expert-like solutions” represent the momentary intuitive judgements that draw on the teacher’s established knowledge – the essence of practical reason in Aristotelian terms<sup>4</sup>.

In this paper, I have considered the nature of teachers’ decision making in the classroom. Drawing on multidisciplinary approach, I have argued how important momentary interactive decisions are in the classroom, how they can shape the character of the lesson and influence the nature of students’ learning experiences. It seems as important as ever to research this decision making further, to better understand the affective dimensions, the culturally embedded routines and strategies that teachers acquire through participation in the professional community (and vicariously as a student, see, Lortie, 2002; Stigler & Hiebert, 1999, for example). An improved understanding of mathematics teachers’ interactive decisions would also inform the design of reform-oriented professional development and initial teacher education.

I suggest the main implication for future research is to give greater attention to teachers’ decision making from a multidisciplinary perspective while using techniques such as stimulated recall. What I have presented here prepares the way for a model of teacher thinking that integrates cognition, affect and the social setting. Further research could develop and test the model.

### Acknowledgements

I would like to pay tribute to the late Professor Malcolm Swan, my PhD supervisor, with whom I did not always agree but always respected his profound insight into mathematics education. It was within the Shell Centre milieu that this line of thinking was born. I also thank Dr Matthew Inglis (Mathematics Education Centre, Loughborough University) who introduced me to the ideas of Type 1 and 2 reasoning, the work of Philip Johnson-Laird and Jonathan Evans on human reasoning from a cognitive perspective. Finally, to my colleagues in the Mathematics Education Research Group and the Culture, Politics and Global Justice cluster in the Faculty of Education, University of Cambridge who have provided helpful formative criticism from hugely diverse disciplinary, philosophical and theoretical perspectives.

### **Rationale**

For TWG 20, 27 papers and 5 posters have been presented. Due to the high number of papers, the TWG20 was divided into two subgroups, A and B. Although the proposals were expected to embrace three intertwined domains, similarly to what occurred previously (CERME10), the focus of the presented papers at CERME11 was mainly on teachers' knowledge. The topic of teachers' beliefs was addressed in several papers, including studies on teachers' conceptions and student teachers' collective orientations, while only one paper focused explicitly on the topic of teachers' identity – also a tendency from previous conferences. Several research by PhD students were discussed.

### **Main topics**

#### **Teacher knowledge**

When TWG 20 first started as a new TWG in CERME9 (2011), most of the discussion was evolving around teacher knowledge models, how they emerged, developed and how they explain teacher knowledge and partly around their comparison. In TWG 20 during CERME11, compared to previous conferences, models were given less attention. Looking back and reflecting on discussions during CERME11, the group has moved from discussing on teacher knowledge models to mostly using models for further exploration of teacher knowledge in various contexts and on different topics (Piñeiro, Castro-Rodríguez, & Castro; Spratte, Euhus, & Kalinowski; Aguilar-González & Rodríguez-Muñiz, in this volume). There has been discussion of how different stakeholders in mathematics education see teacher knowledge. Jacinto and Jakobsen's paper focused on teachers' perception on horizon content knowledge while examining teacher education programs in Malawi. Similarly, Dahlgren, Mosvold, and Hoover studied teacher educators' understanding of mathematical knowledge for teaching. In this paper authors used MKT model (Ball, Thames & Phelps, 2008) primarily to examine teacher educators' views and not their knowledge of teaching mathematics. During the discussions, conceptualizing knowledge from different perspectives gained attention: e.g. Crisan's paper focused on advanced mathematics knowledge of teachers and ways to support teachers in that respect. Similarly, Pehlivan and Aslan-Tutak focused on preservice secondary mathematics teacher knowledge of mathematical representation translations without taking any teacher knowledge model as the theoretical framework but focusing on participants' knowledge of mathematics. When

carrying out research on teacher knowledge, models of the knowledge of mathematics teachers can provide a structure for research. However, as there is a variety of different models, the potential benefits from the structuring role of teacher knowledge models can only be drawn on if the key question is answered why a certain teacher knowledge model is chosen/used and what can be gained from using this specific model. The features of the teacher knowledge models argued respond to specific needs of describing and explain specific phenomena: e.g. integration of beliefs in the models by Carrillo et al. (2018) and Kuntze (2012). The MTSK model (Carrillo et al., 2018) was used in nine papers focusing various perspectives of mathematics teaching such as analysis of development of tasks, university level teaching, secondary school level teaching and policy analysis. Another model, the Knowledge Quartet (KQ, Rowland, Huckstep & Thwaites, 2005), which has been present in several papers in past CERMEs was used by Bretscher (in this volume) to analyse interviews with teachers, and by Karlsson (in this volume) to analyse student teachers' lesson plans.

### **Teacher noticing**

As the notion of teacher noticing has received more and more attention as a potentially meaningful aspect of teacher expertise (Aytekin & Bostan; Zindel, in this volume), it has also played a role in this TWG, in particular as far as its interrelatedness with teacher knowledge, beliefs and identity was concerned (Kilic, Dogan, Arabaci, & Tun, in this volume). The TWG20 group was aware that different definitions and conceptualisations of teacher noticing have been developed and that covering the full range of aspects of noticing would extend beyond the scope of this TWG. During the discussions, the participants acknowledged the need to be precise about the notion of noticing used. There might be intersection domains between aspects of noticing with models of teacher knowledge, for example, the “contingency” domain in the Knowledge Quartet model may be seen as covering some aspects of noticing. Relationships between noticing and teacher knowledge might even imply that noticing gets a “meeting point” for different models of teachers' knowledge. Also Interpretative Knowledge (Ribeiro, Mellone, & Jakobsen, 2016; Policastro, Ribeiro, & Almeida; Di Bernardo, Mellone, Minichini, & Ribeiro, in this volume) could be considered as such a “meeting point” of different teacher knowledge models.

### **Teacher beliefs and identity**

Teachers' knowledge and beliefs are strictly intertwined, as it has been highlighted in a theoretical model used by many researchers who attended CERME11: i.e Mathematics Teachers' Specialized Knowledge (MTSK) model (Carrillo et al., 2018). Among the papers presented in the CERME11 TWG20, several studies make use of the term conception, assumed to include teachers' knowledge as well as their beliefs. Some of the papers presented in TWG20 dealt with teacher beliefs about specific topics: e.g. a study about different countries teacher's beliefs about Inquiry-Based Learning (Huang, Doorman, & van Joolingen, in this volume); two ongoing studies that aim at theorizing models that can be used to analyse and characterize teachers' conceptions of argumentation in mathematics teaching-learning processes and at arguing possible repertory grids to research teachers' conceptions of argumentation (Ayalon & Naama, in this volume; Klöpping & Kuzle, in this volume); a study on teachers' conceptions about learning mathematics through classroom discourse (Kooloos, Oolbakkink-Marchand, Kaenders, & Heckman, in this volume). Other papers showed evidence of

teaches' perspective about how to promote students' creativity (Sánchez, Font, & Breda, in this volume), of teachers' beliefs about the use of experiments in mathematics classroom (Geisler & Beumann, in this volume), and of student teachers' collective orientations on heterogeneity (Tewes, Bitterlich & Jung, in this volume). A transversal-issue discussed was the correlation between beliefs about mathematics and the styles of teaching in different contexts (Safrudiannur & Rott, in this volume). As underlined above, only one paper presented in the CERME11 TWG20 explicitly dealt with teacher identity (Rø, in this volume). Mathematics teacher identity has been explored from a range of theoretical perspectives; however, studies focusing on social practices and structures within which teacher identities develop seem to predominate in the research field (Rø, in this volume). Possible implications of focusing on teachers' identity were discussed in the TWG20, including theoretical considerations made when choosing an identity perspective. Taking an identity perspective on mathematics teacher learning, one can get insight into the participative experiences of (prospective) mathematics teachers, either when entering the profession or when moving across mathematics practices at university and school.

## **Transversal and new issues emerged**

### **Cultural aspects**

During TWG20 discussions the cultural issue emerged in a strong way. Although the cultural and context aspects were always part of research on “teacher knowledge, beliefs and identity”, they often remain overshadowed or were even implicit in the papers. These issues cannot be considered as secondary when investigating on the curricular knowledge needed in different countries, on the teacher education programs, on the methodologies and activities that a teacher designs and develops in his/her classes. Also the use of research products, as well as the impact of the research, is very culturally dependent: e.g., the models used to describe and analyse teacher knowledge and their use in teacher education programs design are under the influence of cultural factors. The work carried out in the TWG20 gave researchers from different countries the opportunity to compare and ask their colleagues for information on different contexts and thus to reflect on how certain approaches and choices are specific to certain realities. It is important to specify that cultural and contextual aspects cannot be reduced to the content of curricula or only to organizational issues (such as the school systems or teacher education programs), but also include the beliefs about mathematics and teaching mathematics, different backgrounds, the roles of teacher educators, teachers and students in teaching-learning processes, the types of research carried out and the models applied to study them. Knowing and trying to understand other cultural contexts can help you better understand your own even though it is always very difficult to be aware and to analyse the features of the culture in which we are embedded. These reflections can be developed in all educational research and, in particular, in the research on “teacher knowledge, beliefs and identity”: in fact, culture shapes teachers, teacher educators, and researcher.

### **Teacher education programs, teacher educators and tasks in teacher education**

In the discussion on teacher knowledge, two transversal elements received attention: tasks, and mathematics teacher educators. The first element was considered as a research goal itself, in research focusing in how tasks aiming to foster knowledge development are built, but also a methodological

tool to gather data about teacher knowledge. The second element regards the crucial role of the mathematics teacher educators (MTE) in the implementation of the tasks and the dynamics of in-service teacher training. The discussion around tasks for developing teachers' professional knowledge focused on three aspects: their design, their use to analyse teachers' knowledge, and their implementation. Concerning design, teachers' knowledge frameworks were used to guide it, using the frameworks' descriptors to structure the elements emphasized. In the papers presented, the design was founded in both MTSK and MKT frameworks, for example focusing on patterns (Aguilar, Ribeiro, & Ponte, in this volume) or on polygons (Montes, Climent, Carrillo, & Contreras, in this volume) or on rational numbers (Policastro, Mellone, Ribeiro, & Fiorentini, in this volume). Tasks were also used as a methodological tool to explore teacher knowledge, in particular, about definition (Codes, Climent, & Oliveros, in this volume), real numbers (Delgado-Rebolledo & Zakaryan, in this volume), and combinatory (Semanišinová & Hubeňáková, this volume). The implementation was slightly discussed as a part of the methodological section in the papers addressing tasks, yet receiving much more attention in the group discussion by emphasizing the role of MTE as the main agent in the implementation of the task. In addition to discussion on MTEs during papers which were not focusing on them, there were also papers focusing on MTEs (Mosvold & Hoover, in this volume; Almeida, Ribeiro & Fiorentini, in this volume). The discussion on TWG20 brought attention on them, as a key agent on the development of teacher knowledge. First, the term 'mathematics teacher educators' is not understood with the same meaning in each context, neither the content taught by them. It generated also a deep discussion the possibility to analyse MTEs knowledge with frameworks focusing (primary or secondary school) teacher knowledge. Second, and specially linked to research design, it was discussed how do MTEs impact on research. Finally, and related to the context-dependent meaning of some terms, teacher education programs received attention in the discussion and also in one paper (Estela-Caldatto & Ribeiro, in this volume), agreeing that researchers, MTEs, teachers and stakeholders need to link research on teacher knowledge, beliefs and identity and the design of teacher education programs.

*Investigating teachers' knowledge for teaching mathematics has been an important theme in mathematics teacher education. In this paper we aim to analyze which mathematical and didactical knowledge secondary mathematics teachers have about patterns and regularities. For this, we developed a teacher education process with mathematics teachers in Brazil during 15 weeks using professional learning tasks (PLT) specially built for this purpose. The research is qualitative-interpretative and data were collected by audio and video recording, with gathering of written documents. The results show that PLT allowed to recognize what mathematical and didactical knowledge teachers had in the beginning of the teacher education process, and how the PLT enabled the development of new professional teacher knowledge.*

*Keywords: Professional learning task, mathematical and didactical knowledge, teaching of algebra.*

## Introduction

To unveil and to understand teachers' mathematical and didactical knowledge (Ponte, 1999) constitutes an important field of research in teacher education and, in particular, when practice is considered as a starting point (Lampert, 2010) for the construction of teacher professional knowledge. This underscores the importance of investigating the role of professional learning tasks (PLT) (Ball & Cohen, 1999; Smith, 2001; Swan, 2007) as a means to foster reflection on teachers' knowledge and to share their classroom experiences.

Regarding the specific field teaching of algebra, researches document the difficulties encountered by teachers in their teaching practice (Doerr, 2004; Ribeiro, 2012). At the same time, researches also highlights the importance of working with patterns and regularities as a promising path for the development of algebraic thinking (Mason, 1996; Twohill, 2015; Vale & Pimentel, 2015).

Thereby, our aim in this paper is to investigate the mathematical and didactical knowledge mobilized by mathematics teachers to solve individually and collectively a professional learning task related to teaching of algebra in basic education about patterns and regularities. To this end, we took a mathematics teachers' education programme as a research setting, aiming to answer the following research question: *In what way does a professional learning task allow (and favour) access to teachers' mathematical and didactical knowledge?*

## Professional learning tasks and teachers' knowledge

In our research, teacher professional learning is a process anchored in classroom practice (Ball & Cohen, 1999; Ponte & Chapman, 2008; Smith, 2001) based on collective activity. Researches by Ball and Cohen (1999), and White, Jaworski, Agudelo-Valderrama and Gooya, (2013) emphasize

the creation of opportunities for teachers to learn each other, in order to break with a type of isolation that is very present and usual when one considers the work of the teacher, thus increasing opportunities for them to start learning in a collective way. Thus, teacher professional learning, in this perspective, are mediated by professional learning tasks (PLT), assumed in our research as

tasks that involve teachers in the work of teaching, can be developed in order to find a specific goal for teachers' learning and takes into account the previous knowledge and experience that teachers bring to their teaching (Ball & Cohen, 1999, p. 27).

PLT may support the access the professional knowledge of the teachers about patterns and regularities. In order to consider the different dimensions of professional teacher knowledge, which will be better discussed later, it must be considered in the composition of the PLT the use of records of practice (Ball, Ben-Peretz & Cohen, 2014), such as protocols of student solutions, parts of curriculum proposals and teaching plans, must be taken into account. These resources allow us to bring aspects of classroom practice into the context of teacher education processes as important components of professional learning tasks (Smith, 2001).

In the perspective of teacher professional knowledge, we are interested in Ponte's perspective (1999), which discusses a view of teacher professional knowledge strongly anchored in teaching practice, arguing that teacher knowledge is action-oriented. In his perspective, this knowledge unfolds in four domains: knowledge of teaching contents, knowledge of the curriculum, knowledge of students and knowledge of the teaching process. For the author, this knowledge

is closely related to several aspects of the personal and informal teacher's knowledge of everyday life as the knowledge of the context (the school, the community, the society) and the knowledge that he/she has of himself (Ponte, 1999, p. 3).

Regarding the teachers' mathematical and didactical knowledge about patterns and regularities and their connections with mathematics teaching, we should consider how relevant it is that teachers mobilize knowledge that make possible to understand the students' algebraic thinking and to support the overcoming of difficulties they usually have regarding the generalisation of numerical and geometrical patterns (Orton & Orton, 2005). In order to be able to mobilize mathematical and didactical knowledge on the subject matter, it is necessary to consider, during the teacher education processes, professional learning tasks that contemplate mathematical situations involving different types of patterns in which algebraic expressions that generalise them are asked for (Zazkis & Liljedahl, 2002).

In order to promote discussions and reflections in the teacher education process regarding teachers' mathematical and didactical knowledge, teacher educators should stimulate the development of PLT using some specific practices for this purpose (Stein, Engle, Smith & Hughes, 2008).

Stein *et al.*, (2008) propose five practices developed in classroom, which are called: anticipating, monitoring, selecting, sequencing and connecting. For this purpose, the authors argue that anticipating is the process in which the teacher, before taking the task to his/her classroom, anticipates the possible resolutions of the students and their possible difficulties. In the classroom, monitoring is the process in which the teacher will monitor the discussions that occur in small groups and thus he/she will select the most interesting resolutions to share with the classroom, whether they are unusually resolutions like those that may present errors and difficulties of the

students. When the discussion is open to the whole classroom, the selected groups are presenting their resolutions within a sequencing, drawn up by the teacher. With this, the teacher should connect the student's resolutions with the mathematical knowledge proposed in the task in question. Thus, from these five practices, we conjecture that they can also help to foster discussions and mathematical and didactic reflections when used in teacher education process.

## Research methodology

**Context of the study.** The teacher education process in which the data were collected had the general aim of developing and expanding participant teachers' mathematical and didactical knowledge regarding patterns and regularities in school mathematics. It was carried out during 15 weekly meetings of 4 hours, led by the first and second authors of this article. The meetings combined moments of (i) individual work, (ii) work in small groups, and (iii) plenary collective discussions. The participants were mathematics teachers (pre-service and in-service) and the activities were mostly carried out at the university, with 3 meetings held at basic education schools. The work sessions included moments of theoretical studies (a total of 8 hours) and *hands on* work, which were mediated by professional learning tasks developed by the leaders of the meetings.

**Participants and developing of the PLT.** The participants of our study were teachers who teach mathematics in Brazilian secondary schools. In relation to the PLT that we explore in this paper (Figure 1 below), for the begging of the teacher education process we counted on the participation of 42 teachers, being 10 pre-service teachers and 32 in-service teachers (7 of these with no classroom experience). Of the 32 in-service teachers, 17 had been graduated for less than 5 years; 7 had between 5 and 10 years of teaching practice; 8 had more than 10 years of teaching practice. For the implementation of PLT, the 42 participants were distributed in 9 groups (3 to 6 participants), organized by the facilitators so that in all groups there were (i) teachers with and without classroom experience, and (ii) pre-service and in-service teachers. Teachers groups were built in this manner in order to promote the exchange of experiences and knowledge among participants. Of the three facilitators present, two were teacher educators and researchers in teacher education.

Observe the following squares and the strategy used to calculate the sum of the first odd numbers, starting from 1.

### Figure 1: Example of Professional Learning Task<sup>1</sup>

Thus, PLT's main goal was to raise teachers' prior knowledge about patterns and regularities. It was planned for and developed in three moments: individual, small group discussion, and plenary collective discussion. These moments were accompanied and encouraged by the facilitators who, to favour the collective discussions, using five practices presented by Stein *et al.*, (2008).

**Data sources.** Our study follows a qualitative research approach (Bogdan & Biklen, 1994), under the interpretive paradigm (Crotty, 1998), with the data collection taking place through video and audio recordings (both within each group as with the whole group) and through gathering of written documents resulting from the development of the PLT. The analyses considered: (i) teachers' individual notes; (ii) notes written by small groups of teachers; (iii) the audios of small group discussions; and (iv) the video of the collective discussion. The audio and video records were analysed in full, in articulation with the documents produced, and allowed the organisation and analysis of the data in order to identify the mathematical and didactical knowledge about patterns and regularities contemplated in PLT.

## Results

**Individual work.** We begin the analysis considering teachers' individual work. It was observed, in general, that teachers found it difficult to mobilise mathematical knowledge to solve the mathematical situations presented in the PLT, regardless of their school year. The teachers sought to describe the observed mathematical pattern and to present an algebraic expression that represented the generalisation of this pattern. Afterwards, in the part of the PLT that explored the didactical knowledge – in relation to the students and in relation to the teaching processes – the teachers said that (i) they would have difficulties to solve the mathematical task by missing the perception of a pattern in the sequence, therefore having trouble in writing an algebraic generalisation; (ii) regardless of the school year, the students would use strategies for solving mathematical tasks by using counting processes or constructing the other elements of the sequence presented, just as the teachers themselves did, as can be seen in the statement<sup>2</sup>:

T7: [The students will have] The same difficulties I'm having.

Still with regard to didactical knowledge, the teachers said that, in their classroom, they do not propose mathematical tasks similar to those they were working on because (i) they have a tight schedule; (ii) students have difficulty in solving tasks of this kind; (iii) they do not have the adequate preparation to work with this type of tasks, as stated by teacher T8:

T8: I did not use this type of task because I am not used to let students build their own knowledge. So, my concern in learning how to support them build the formulas, and not going to the classroom with ready-made formulas.

**Group work.** At a second moment, the teachers begun working in small groups, comparing their own responses with those of their peers and, through collective discussions, reflecting on their mathematical and didactical knowledge regarding patterns and regularities. During the discussions

<sup>1</sup> Due to the space constraint, we present the PLT used with the teachers of grades 8-9, since the PLT structure of the other teachers (grades 6-7 and 10-12) was the same, changing only the mathematical situation of part 1 of the PLT.

<sup>2</sup> We use T for teacher-participant and TE for teacher educator/facilitator.

in small groups, many similarities were observed in the way they had worked individually, but, nevertheless, it is worth mentioning that the groups thought it difficult to find new mathematical strategies for solving tasks, even when working in groups. Only three groups stated that they found different solutions. During the small group discussions, the teachers emphasised that the students would be able to use counting processes or build the other elements of the sequence, but they would still have a hard time finding the pattern in the sequence, and even more in writing the generalisation in algebraic expression. In their discussions, the teachers recognised that, although they had difficulties in carrying out tasks similar to those in the classroom, this approach is very important for students to overcome their difficulties and to build their knowledge through tasks – and not just through “teacher's talk”.

While teachers worked in small groups, the facilitators carried out the practices proposed by Stein *et al.*, (2008) in order to prepare the next stage of the development of the PLT, namely, plenary collective discussions, which included three moments: (a) the first, aimed at sharing the teachers' mathematical knowledge and sharing unusual answers; (b) the second, aimed at sharing teachers' didactical knowledge regarding the students' difficulties; and (c) the third, aimed at sharing whether teachers used mathematical tasks of this kind in their classrooms.

Observe at the pictures and answer:

- a) How many people can settle at the tables, if we arrange 3 tables as shown beside?
- b) Write an expression that gives the number of people accommodated at 13 tables.
- c) Complete the general conclusion: the number of people is \_\_\_\_\_  
(Attention: Do not forget that the number of people depends on the number of tables).
- d) Write the conclusion in a formula where the letter  $p$  represents the number of people, and the letter  $m$ , the number of tables.

**Figure 2: Example of Professional Learning Task<sup>3</sup>**

**First part of the plenary collective discussion.** Throughout the first part of the plenary collective discussion, it was perceived that, in fact, the teachers themselves thought it difficult to explain different solutions to the other participants, since they always tried to rely on the mathematical properties of Arithmetic Progressions (AP), exploring little other possible strategies. T1's statement shows us this:

T1: The exercise was exactly the same [as that of the previous group] and then we get pretty much the same idea. I even got into the same situation [as the teacher who spoke before]. I started with an AP, I did the AP formula, I did the computation with the AP and I said: “hold on... The grade 6 student will not think about the AP”, [see Figure 2] and then we begin thinking in other ways (...) and we arrived

<sup>3</sup> Due to the space constraint, we present only mathematical situation of the PLT used with the teachers of grades 6-7, The complete PLT structure was the same presented in Figure 1

at  $p = 6m + 2$  [ $p$  = people and  $m$  = tables] and thinking about AP, I got the relation  $a_{13} = 8 + (13 - 1) \times 6$  and the result equals 80.

It can be seen in this statement, which was recurrent in the other groups, how teachers were not distant from the concept of arithmetic progression and also of what their students could think and do (although it had been reinforced by the facilitators that at that moment the mathematical knowledge of the teachers themselves was being discussed). In counterpoint to this idea, teacher T4 said:

T4: The answer [of our group] is different from that here [the answer that was already written on board,  $S_n = n^2$  regarding to Figure 1] (...) So it would start at zero and go up to  $n$  [the teacher then writes down on the board  $\sum_{i=0}^n 2n - 1$ ].

T5: But this [solution] is for the 9<sup>th</sup> grade?

T4: We did not think about the student, this solution is ours.

It is interesting to note here that this group stated that it worked with the two solutions exposed in the dialogue, one that would possibly be that of the students, and another, that would be theirs. With this, facilitator TE2 asked:

TE2: For you, the meaning of  $n$  is the same in the two expressions [ $S_n = n^2$  and  $\sum_{i=0}^n 2n - 1$  ]?

T4: Yes!  $n$  indicates the natural numbers 0, 1, 2...

Such confusion presented by teachers about the meaning of the variable does not mean necessarily lack of mathematical knowledge, probably a difficulty orally expressing such knowledge.

With this, we perceive that the group of teachers present different representations about the generalization of patterns but they have difficulties in presenting their justifications of these representations.

**Second part of the plenary collective discussion.** Continuing with the plenary collective discussion, now focusing on the dimensions of teachers' didactical knowledge, teacher T2 pointed out that the students could construct a numerical table with the relation between the number of tables and people (Figure 2) and this would help him to realise the pattern. On the other hand, teachers T9, T10 and T6 had other concerns:

T9: At least in the few years that I have been in the classroom, the biggest problem I encounter is the algebraic part. (...) Teaching them [the students] that they have to solve the exercise in a way and still look at its generic part. I believe it is very difficult for the 6<sup>th</sup> and 7<sup>th</sup> graders.

T10: I think like this: If you do not insist... The student has difficulty but if the teacher has already been working this in the classroom, I think the student can get it.

T6: But that is the purpose of the activity, for the teacher to know the students' previous knowledge, so he can get to algebra.

At this point, the facilitator TE1 suggested that teachers were only thinking about the difficulty of the symbolic representation, but if students in any school year could explain the generalisation without the use of symbols and, even so, they already be a way of thinking algebraically.

This led to the establishment of a controversy in the plenary collective discussion, as pointed out by teacher T3:

T3: It may be the way we work with students. We give the contents and then the student finds it easy. We do not make the student an investigative being. We come and give him/her the formula to solve the problem. Wouldn't the lack of learning be one of the great problems in the classroom? The question that we don't go there and make the child investigate, search for things. Shouldn't we invest in this line of child's reasoning?

That thought - expressed by T3 - took the proportion of a challenge to be pursued by the group of teachers and facilitators throughout the teacher education process, that is, that the teachers' work with their students should become a more investigative exploratory approach rather than just follow a traditional approach to teaching.

## Discussion and Conclusion

By developing the PLT, it was possible to realize that the teachers showed some difficulties in their mathematical knowledge regarding to the concept of variable what could implicate the recognition of patterns and regularities and the formulation of algebraic expressions to represent complex mathematical sequences (Zazkis & Liljedahl, 2002). In the dimension of didactical knowledge (Ponte, 1999), it can be noted that the teachers, possibly due to the fragility in mathematical knowledge, did not feel safe and comfortable to use tasks with their students such as those proposed in the PLT. From the point of view of teachers' knowledge of students, their solution strategies and difficulties, we noted that, throughout the development of the PLT, the teachers conjectured about students' algebraic thinking and how they could help them to overcome the difficulties they could present regarding the generalisation of numerical and geometrical patterns (Orton & Orton, 2005).

Regarding the structure of PLTs (Ball & Cohen, 1999; Smith, 2001), we conclude that the results show their potential to favour the mobilisation, connection and (re)construction of mathematical and didactical knowledge about patterns and regularities in the teaching of mathematics and, in special, to establish relations with classroom practice. In particular, we highlight as potential of the PLT proposed in this paper, the use of the five practices to prepare and lead (plenary) collective discussions (Stein *et al.*, 2008). This framework enabled the group of teachers and facilitators to share knowledge and experiments that made teachers, for example, (i) wonder both why they do not provide investigative and challenging tasks for students to explore different kinds of numerical and geometric sequences, and (ii) how such work may contribute to the development of algebraic thinking in their students. Therefore, we believe that the use of PLT in teacher education process can help to unveil and understand the teachers' mathematical and didactical knowledge.

# Mathematics Teachers' Specialized Knowledge Model as a Metacognitive Tool for Initial Teacher Education

Álvaro Aguilar-González<sup>1</sup> and Luis J. Rodríguez-Muñoz<sup>2</sup>

<sup>1</sup>Universidad de Oviedo, Spain; [aguilaralvaro@uniovi.es](mailto:aguilaralvaro@uniovi.es)

<sup>2</sup>Universidad de Oviedo, Spain; [luisj@uniovi.es](mailto:luisj@uniovi.es)

*Mathematics specialized knowledge models for teachers have been used as a conceptual framework for defining how teachers' knowledge is implemented in the classrooms, as well as for guiding the design of initial teacher education (ITE) programs. In this communication, besides the design of the ITE program, we present how the model of Mathematics Teacher's Specialized Knowledge (MTSK) has been used as a metacognitive tool enhancing primary and early-childhood teachers to reflect about their own professional competencies, to self-assess in relation to the different subdomains in the model, and to start acquiring research related skills during a postgraduate ITE program.*

*Keywords: initial teacher education, MTSK, research skills, specialized knowledge model.*

## Introduction

Teachers' knowledge models emerged in the 1980s, mainly from the seminal work of Shulman (1986), as a theoretical framework characterizing the knowledge that teachers need to operate in order to carry out their teaching tasks. In addition to non-specialized models such as T-PACK (Mishra & Koehler, 2006), other models of specialized knowledge were developed in the field of mathematics teaching. Thus, the Mathematical Knowledge for Teaching (MKT) model by Ball, Thames and Phelps (2008) stood out. These authors were interested in the study of professional knowledge, basically because specific knowledge, besides mathematical knowledge, was revealed as necessary to teach mathematics. In other words, a teacher has to know different but not less demanding mathematics than other professionals.

At CERME8, the Mathematics Teacher's Specialized Knowledge (MTSK) model was presented by Carrillo, Climent, Contreras, and Muñoz-Catalán (2013) as an evolution of the studies of Shulman (1986) and Ball et al. (2008). MTSK considers the specialized character of the teacher's knowledge in an integral way in every subdomain, whereas MKT included the mathematics teacher's specialized knowledge into a single subdomain.

The context for this experience is strongly dependent on the introduction of European Higher Education Area in Spain, that opened up the possibility that early childhood and primary education graduates could access to postgraduate programs (master degrees, and maybe further doctoral studies). Master level is not a requirement for becoming an in-service teacher in Spain, but in the recent years is becoming more popular among recent graduates (in part, because the master level is a requirement in other UE countries). In Spain there are master degrees oriented to a specific topic (didactics of mathematics, for example) but for early childhood and primary education graduates most of the master programs are devoted to provide them with general innovation and research skills (since early childhood and primary teacher are generalist profiles in Spain, only specialized for certain topics in primary as Physical Education, Foreign Language, Music and others, but not for Mathematics). In

this context, the current research was designed with a twofold objective. Firstly, to find out whether, at master level, training graduate teachers about models of specialized mathematical knowledge improves metacognition about their professional development and identity as mathematics teachers. Secondly, to find out whether this training (together with other topics) promotes basic research skills. Consequently, two research hypotheses were formulated: (H1) Including models of specialized mathematical knowledge in the syllabus of the master program for graduate teachers favors metacognition about their profession, and (H2) Including models of specialized mathematical knowledge in the syllabus of the master program for graduate teachers promotes research skills in educational research.

This communication is structured as follows: first, a theoretical framework is described and metacognition is framed within the context; later, the methodological design is described together with the population and the sample, and the data collection process; finally, results are presented and, subsequently, the discussion together with the conclusions derived from the study.

## **Theoretical Framework**

The MTSK model is fully developed in Carrillo et al. (2018), it is composed of the domains Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK), which, in turn, are divided into 3 subdomains each. In addition, the core of the model includes the mastery of teachers' beliefs about mathematics, its teaching and learning, permeating the knowledge and giving meaning to their practice. The MK domain encompasses knowledge of the connections between concepts, structuring ideas, procedure reasoning, proving, and different ways of proceeding in mathematics, also considering the knowledge of mathematical language. Within the MK we find the following subdomains: Knowledge of Themes (KoT); Knowledge of the Structure of Mathematics (KSM); and Knowledge of Mathematical Practice (KPM). On the other side, the PCK refers to teacher's knowledge of mathematical content as an object of teaching and learning. The PCK domain is divided into three subdomains: Knowledge of the Teaching of Mathematics (KMT); Knowledge of the Learning Characteristics of Mathematics (KFLM); and Knowledge of the Mathematics Learning Standards (KMLS).

Additionally, it is convenient to specify the scope of the discussion on metacognition and research skills. The majority of theoretical frameworks used in metacognition focus on two components: those dealing with declarative and procedural knowledge, and those dealing with the regulation of that knowledge when an individual performs a task (Schraw, Crippen, & Hartley, 2006). In our approach, we handle the latter meaning when designing the training activity for the graduate students (Lombaerts, Engels, & Athanasou, 2007). The proposed activity is aligned with what Zimmerman (1990) states as one of the key features which can be seen in most definitions of self-regulated learning, that is, systematic use of metacognitive motivational and/or behavioral strategies. Therefore, we are considering higher evidence of metacognition when the graduate students are not only aware of their own thinking but also use it as an instrument to regulate their own learning experience when doing the task.

On the other hand, according to Spanish Higher Education Qualifications framework, the acquisition of research skills should start in the postgraduate training. In other words, the master degree is

conceived as the prior stage of the research training, which is properly developed during the PhD degree. Then, a master graduate should acquire a minimum level of research skills allowing him/her starting, under supervision, in active research teams. Literature is abundant on so-called research-based learning, especially in the field of STEM (Science, Technology, Engineering and Mathematics) (see a review in Camacho, Valcke, & Chiluita, 2017), but it is scarce about how to develop this competence for educational research, specifically on how to characterize it during ITE postgraduate programs.

To this end, we align ourselves with the theoretical position defined in Moreno Bayardo (2005), who defines training for educational research in terms of the development of research skills. Specifically, for this experience, we are placed in the so-called “Nucleus G: Metacognitive Skills”, where the author argues that “the human being encounters the need to develop (and, in fact, in many cases he achieves it) metacognitive skills before getting involved in deformation processes for research” (Moreno Bayardo, p. 530). It should be pointed out that, although there are works whose explicit objective is fostering metacognition in the professional development of teachers (e.g., Rojas & Deulofeu, 2013), within the Spanish context there is only one former experience (Pascual & Montes, 2017) using a specialized knowledge model to develop metacognition, but it was during the undergraduate ITE and, therefore, activity did not involve research skills, whereas, our research focus on how to help the graduate students to move from a teacher identity to a potential research identity.

## **Methodology**

### **Population and sample**

The population of this study consists of graduates of Early Childhood and Primary Education who are enrolled in a master degree aimed at research and innovation skills. Several masters with these characteristics are taught in the different Spanish universities, but we have only had access to data from the University of Oviedo, in whose Master Degree in Research and Innovation in Early Childhood and Primary Education in the academic year 2017-2018 there were a total of 35 students enrolled. Therefore, it is an intentional non-random sampling, and the sample is formed by 32 individuals who completed the experience and the survey (response rate of 91.42%).

### **Educational context**

The master degree in Research and Innovation in Early Childhood and Primary Education at the University of Oviedo is oriented to graduates in both educational stages for training them as future researchers and professionals in the field of learning and teaching. The subject in for which the intervention was designed is Research and Innovation in Didactics of Mathematics (5% of credits in the program). We remark this is not a specific master program in mathematics education, but generalist, and this fact hardens deepening into mathematics educational issues. One of the five basic competences of this master program aims to acquire sufficient skills to identify trends in innovation and research in the knowledge areas involved, and discussing their compatibility with the explicit beliefs and theories of the teaching staff. Taking the context into account, we proposed the experience described below for promoting the aforementioned competence.

### **Intervention planning**

Previous lectures to the intervention had been developed, during 10 hours, for presenting the meaning of research and innovation in mathematics education, as well as to identify the work that in-service teachers can do within these fields. Among these general ideas, the notion of professional knowledge of the teacher was used, and more specifically, the notion of specialized knowledge in mathematics was implicitly involved to perform different tasks developed by the students. Also, main research lines in mathematics education were described by reading and discussing examples of papers. But, in this communication we focus on the work that was carried out during two work sessions in the classroom in which the activities related to the presentation on the professional knowledge of the teacher and the use of the MTSK model were presented and carried out. In the first session there was a training, led by the professors, on the research problem of models to describe specialized teachers' knowledge. This session explained the different theoretical positions on teacher knowledge, the differences between content knowledge and pedagogical knowledge and their intersections, the genesis of the first models of specialized knowledge and the role of teacher beliefs and conceptions in their interaction with knowledge. In the second session, the MTSK and its subdomains were dealt with in detail. Afterwards, divided into small groups, the students carried out a work based on the transcription of a fragment of real class of Early Childhood Education (4 years old level) where the teacher worked with geometric bodies. The main objective of the activity carried out by the teacher is the recognition of different geometric bodies and the identification of their elements (faces, edges, vertices, etc.). The graduate students had to identify the subdomains and categories of knowledge of the MTSK present in the class transcription. Finally, they had to respond individually to an anonymous questionnaire, which is presented in the following section.

### **Assessment instruments**

In addition to the aforementioned deliverable group task about identification of subdomains of the MTSK model, students had to answer a questionnaire consisting of context questions (age, sex and teaching experience, and whether they had been previously trained or not about the models of knowledge), and of 7 questions for assessing the usefulness of the model or models like it in the professional teaching environment (with Likert scale responses from 1 to 5). Finally, 3 open-ended questions were posed which are based in the nature of subdomains of MTSK. The instrument had been content validated through a pilot carried out in the previous year, which resulted in removing two of the initial open-ended questions (because of redundancy and misinterpretation).

## **RESULTS**

The sample ( $n=32$ ) was composed by 19 women and 13 men, with average age 26.25 years old (median 24). Only 6 students have had experience as formal teachers (5 at primary and 1 at early childhood level), that is, most of the students were recently graduated teachers without further experience than the internship. Also, 6 stated that they had previously heard about teacher knowledge models. And only 1 of the participants stated that he/she was yet aware of specialized models for mathematics. Table 1 shows the mean, median and standard deviation of all the Likert type questions (1=absolute disagreement to 5= absolute agreement with the statement).

As for the open-ended questions, below we point out some of the most significant or frequent ones. To the question "Would you add anything to the subdomains MK and PCK to better describe the

activity of the mathematics teacher?”, the most frequent answer was like “I do not consider myself sufficiently qualified”. One student considered that “the affective aspects of the teacher-student relationship should be more pointed out”. Another one remarked that “it would incorporate the methodologies in a more explicit way, including the different types that exist”.

Statement	M	Me	DT
1. I believe that it is positive for my training as a teacher to know a model that describes the knowledge of mathematics teachers.	4,03	4	0,73
2. For my daily life as a teacher, I believe that these theoretical models do not improve my training.	2,44	2	1,14
3. The work about knowledge models has allowed me to reflect on professional aspects that I had not thought about.	3,81	4	1,03
4. The knowledge models have helped me to structure ideas which I had thought about my profession, but not in such a formal way.	3,16	3	0,92
5. I find the work on knowledge models interesting, but of little use for my professional future.	2,72	3	1,12
6. I think knowing these models is interesting as a general culture but it will not be something I will apply when I have to program or teach.	2,91	3	1,26
7. I consider that these models help to criticize and reflect on my activity as a teacher.	4,06	4	0,86

**Table 1: Mean (M), median (Me) and standard deviation (DT) of all the Likert-type answers.**

Second open-ended question was “Has this model allowed you to reflect on any aspect of your professional development that you had not previously thought about? Which one?”. There were some self-critical answers, from the point of view of metacognition, such as: “that I have insufficient mathematical training” or “about my scarce mathematical and didactic training”. Other answers even advanced in metacognition, at a higher cognitive level. Thus, some students stated that the model has helped them to reflect on specific aspects such as “the importance of knowledge of resources, materials and ways of presenting the content” or “the importance of teacher's knowledge, not only of the subject itself, but also of the didactic part”; and, in some cases students established relations between categories: “the relationship between current and previous contents”, “beliefs about mathematics or its teaching/learning and the scope they may have in the teaching process”, “the need to spin each content of the curriculum with other elements whose relationship does not seem so direct” or “the need to be aware of [...] the learning standards used in other countries”.

Finally, in response to the third open-ended question: “Has the use of this model motivated you to reflect on mathematics as a discipline or on your professional development?”, the most frequent responses referred to “considering my professional development in different facets” or equivalent. Answers with a greater level of deepening, were less frequent: “that research is a source of educational improvement”, “to overcome the myth of difficulty or fear of mathematics” or “I would like to see the analysis of the knowledge that is put into practice in classes of different educational levels”. We particularly highlight the following answer: “[this model] reminds me of the concept of metacognition and, in a similar way, I see its usefulness”. Finally, this answer also denotes progress in metacognitive processes: “[the subdomain of] the characteristics of learning mathematics in a specific subject have seemed very interesting to me, and I would have to take it into account when planning my classes”.

## DISCUSSION AND CONCLUSIONS

Results of the Likert answers are homogeneous in terms of the analyzed context variables (sex, age, professional experience), hence, statistical analyses have not been included. The values of the Likert scale show that there is a high degree of agreement with the statements expressed in positive. Specifically, the agreement is very high in statements 1 and 7. On the other hand, when the statements are posed negatively the agreement is considerably reduced (numbers 2, 5, and 6). In addition, in statement 3 the degree of agreement is also quite high, although the dispersion is greater due to the existence of more extreme values. Finally, with statement 4 a problem of interpretation arises, since values are grouped symmetrically around 3, which indicates that perhaps the duality of the question should be reformulated (this had not happened in the piloting). From these results, we can conclude that, overall, the activity motivated the reflection of future teachers and they considered it useful for their professional activity, which is something authors did not expect initially, due to the generalist background of the graduate students. In addition, the link between research and daily activity as a teacher in the classroom is recognized, albeit less clearly. The metacognitive facet is also implicitly recognized in the answers (statements 3 and 4).

From the analysis of the open-ended questions, we can deduce that students found more difficult to formalize their opinions, since around half of the answers were very short or blank. Based on evidence from longer answers, regarding MTSK subdomains, for most of the students the training was insufficient to be able to critically judge the model; this evidences that explicit training on models was short. Even though, it seems interesting to us pointing out that two students felt that temporal programming is not sufficiently represented in the model. It is also noteworthy the answer referring to the insufficient representation of the affective relationship between teachers and students. This answer can be interpreted from two of the domains of the MTSK model: firstly, the contribution made by the MTSK model in the didactic domain is to link the content of the subdomains to the relevance of the relationship with the mathematical content, so that the affective relationship to which that response refers would not be included in that domain; on the other hand, it could be aimed at mastering the teacher's beliefs, attitudes and emotions towards mathematics and its teaching/learning as central elements, intimately related to professional identity, where the teaching staff give the students a very specific role when working in mathematics. There is a much greater reflection deepening in the answers to the second open-ended question. For example, self-criticism is expressed regarding the background in mathematics and its didactics. Other answers show a deeper understanding of the model, since they reveal relationships between different components of the subdomains (curricular organization, permeability of teachers' beliefs and conceptions, international learning standards, etc.). Answers to the third open-ended question also go in depth. Especially, those about the use of the model as a metacognitive tool, which seems to be completely aligned with the objectives of this research, or other answers that, without explicitly expressing metacognition, do it implicitly by the establishing relations between teaching practice and the knowledge of teachers' knowledge models.

In summary, we consider that data support the veracity of hypothesis H1, about the improvement of metacognitive processes through this activity. This is consistent with Rojas and Deulofeu (2013), although they did not explicitly use a knowledge model. On the contrary, we do not have sufficient

evidence to maintain hypothesis H2, related to promotion of research competencies. In this case, we understand that graduate students' identity is closer to a teacher identity and far from researcher one, which underlines the role of identity, as an important factor in the teacher's understanding of professional life (Beauchamp, 2009). We also believe that we have had little impact on this facet during the intervention, which resulted in the knowledge model being considered more as a tool for self-assessment or reflection rather than as a field of research.

We believe that, as in Pascual y Montes (2017), it is clear that by encouraging the critical and reflective attitude of students we obtain information that can be used in the design of training, especially in the reorientation of training in research skills. This reflection itself is essential in the professional development of mathematics teachers (Schön, 1983) but, in addition, it also provides us critical information from the user of the ITE program about the validity of the training proposal. In our case, we found that focusing on just one of the nuclei of Moreno Bayardo (2005) has not been enough for training research skills in mathematics education among generalist master students. One limitation of our work comes from the instrument, because Likert scales could miss richer students' thinking about the task, therefore we plan to overcome this in the future by using semi-structured interviews. Obviously, the sample is also limiting but, in this case, we are constrained by the scope of this educational programs and by the possibility of getting access to other universities.

We consider that this work opens a promising path for future research. Thus, we propose to go deeper into this working methodology for promoting metacognition and constructing recently graduate teachers' identity as future educational researchers (Hong, 2010). This approach will allow us to obtain a greater connection among the topics of the training and, thus, achieving a better development of researcher identity, which we think it is our main challenge within this ITE master program. In addition, we will also analyze from the descriptive and reflexive points of view the productions of the students in the task of analyzing a transcription of a real class, that was linked to the one presented here. By making this, we will complete the double perspective that we want to study on metacognition: self-assessment (the one already approached here) and peer-assessment. Finally, we also propose to redesign the activity on the basis of the revised Bloom taxonomy (Anderson & Krathwohl, 2001), so that we can cognitively classify the levels of students' responses.

## Knowledge of a mathematician to teach divisibility to prospective secondary school teachers

Marieli Vanessa Rediske de Almeida<sup>1</sup>, Miguel Ribeiro<sup>1</sup>, Dario Fiorentini<sup>1</sup>

<sup>1</sup>State University of Campinas, Brazil; [marieli.almeida@outlook.com](mailto:marieli.almeida@outlook.com); [cmribas78@gmail.com](mailto:cmribas78@gmail.com); [dariof@unicamp.br](mailto:dariof@unicamp.br)

*Mathematics teachers' knowledge has been studied extensively in the last decades, especially in research building on Lee Shulman's work. However, the same emphasis has not been placed on research on the mathematics teacher educator's (MTE) knowledge. Notwithstanding, the concern to characterize the knowledge of these educators has been emphasized in recent studies of mathematics education and models for knowledge of MTEs have appeared in literature. In this perspective, we present an episode which occurred in a Number Theory undergraduate classroom, where a mathematician, who acts in teacher preparation, demonstrates Euclid's division algorithm theorem. The data, which is part of a case study, is analyzed with the objective of identifying indicators of knowledge of MTEs. Among the results, knowledge of MTEs emerge in relation to knowledge of topics, knowledge of the structure of mathematics and knowledge of practices in mathematics.*

*Keywords: Mathematics teacher educator, mathematician, number theory, Euclid's division algorithm theorem, Mathematics Teachers' Specialized Knowledge.*

### Introduction

One of the roles of a Mathematics Teacher Educator (MTE) is to promote Prospective Mathematics Teachers (PMTs) knowledge in order to make them capable of establishing connections between teacher education and their practice. According to Jaworski (2008, pp. 1), MTEs "are professionals who work with practicing teachers and/or prospective teachers to develop and improve the teaching of mathematics". Considering that the knowledge of Mathematics Teachers (MT) is specialized, regarding the perspective of the Mathematics Teachers' Specialized Knowledge - MTSK (Carrillo-Yañez et al., 2018), the work of the MTE is even more important. In this sense, this work intends to contribute to research about the knowledge of the MTE and its role in teacher education, particularly, in a Number Theory course for PMTs.

Even if Number Theory has many connections with school algebra, many MTs understand this topic as being unrelated to their pedagogical practice (Smith, 2002). The theme divisibility, for example, is frequently treated by PMTs as being a trick or a procedure to be memorized, rather than a relation between integer numbers (Zazkis, Sinclair, & Liljedahl, 2003).

The topic divisibility is present from the earliest years of the schooling, including division of natural numbers for example. The integer numbers are gradually introduced in the mathematics school curriculum and some divisibility criteria are presented. In this context, there is a natural underlying question: Why is Euclid's division algorithm valid? This question is answered in a Number Theory course for PMTs, where the Euclid's Division Algorithm Theorem is presented.

In Brazilian universities, mathematicians are mostly responsible for the mathematical preparation of PMTs. These professionals "act as teacher educators de facto, without explicitly identifying

themselves in this role” as claimed by Leikin, Zazkis and Meller (2017, pp. 2). In this scenario, our foci of research is the knowledge these professionals reveal in their teaching. These mathematicians, who are eventually in the role of preparing PMTs, have a solid knowledge in the scientific field of mathematics and aim to develop research in this field and, on the other hand, their pedagogical content knowledge arises from practice (Fiorentini, 2004).

This paper is part of a broader research project which aims to understand and characterize, in the scope of Number Theory, the specialized knowledge of those who act as mathematics teacher educators. In this paper we address the particular research question: *What elements characterize the specialized knowledge of a mathematics teacher educator in relation to Euclid’s division algorithm theorem?*

## Literature review

The knowledge of the MTE is different than both the knowledge of the PMT and the knowledge of the MT (Jaworski, 2008; Zopf, 2010; Contreras et al. 2017). Jaworski (2008) called this knowledge Mathematics Teacher Educator Knowledge, which has particular aspects as well as common points with both the knowledge of the PMT and the knowledge of the MT. In the intersection, they need to know: mathematics, the pedagogy related to mathematics, and the curriculum which the mathematics teacher based their work. Furthermore, the MTE also needs to know: both the professional and the research literature linked to the teaching and learning of mathematics, to know teaching and learning theories, and to know research methodologies that investigate teaching and learning on schools/educational systems.

Zopf (2010) observes that the difference between the knowledge of the MTE and the knowledge of the MT lies in the mathematical content. While the teacher teaches mathematics, the MTE teaches the knowledge to teach mathematics. The teaching purposes are also different, since the children learn mathematics for themselves, while the teachers learn mathematics for teaching their students. Therefore, Zopf (2010) proposes the Mathematical Knowledge for Teaching Teachers (MKTT) in order to describe the knowledge of the MTEs, which includes the knowledge necessary for teaching.

Building on Shulman's work, Carrillo-Yañez et al. (2018) divide the knowledge of the mathematics teacher into two domains: Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK). Thereafter, Contreras et al. (2017) state that the knowledge mobilized by MTEs and teachers present differences when MK and PCK are considered. The differences in MK are related with the fact that the knowledge of the MTE is larger in terms of reach and depth, that is, the mathematical knowledge of the MTE has a more coherent and solid theoretical structure, besides the MTE has more experience with the validation/construction of the mathematical knowledge. On the other hand, PCK contains knowledge about the characteristics of learning of the PMTs, knowledge about how to teach the content of the teacher education and knowledge of different ways to organize the content of teacher education. In this paper we will focus on the MK of the teacher educator participant.

## Teacher educator’s knowledge: theoretical perspective

In Carrillo-Yañez et al. (2018), the authors discuss their Mathematics Teachers' Specialized Knowledge (MTSK) model. In this model, it is considered that the teacher’s knowledge to teach is

specialized and that the MK is subdivided into three subdomains: the Knowledge of Topics (KoT), the Knowledge of the Structure of Mathematics (KSM) and the Knowledge of Practices in Mathematics (KPM). On the other hand, the PCK is also subdivided into three subdomains: the Knowledge of Mathematics Teaching (KMT), the Knowledge of Features of Learning Mathematics (KFLM) and the Knowledge of Mathematics Learning Standards (KMLS). At the center of the model, are the domain of the teachers' beliefs, which are related to all subdomains. In this paper, because we are interested in the knowledge of a mathematician who works in teacher education, we will focus on his Mathematical Knowledge.

KoT includes knowledge of procedures, definitions and properties, representations and models, registers of representations and applications. The KSM subdomain includes knowledge of connections between mathematical items, such as connections based on simplification, connections based on increased complexity, auxiliary connections and transverse connections. In its turn, KPM includes knowledge about demonstrating, justifying, defining, making deductions and inductions, giving examples and understanding the role of counterexamples. In the context of Number Theory, particularly in the scope of the Euclid's division algorithm theorem, the MTE knowledge includes, for example:

KoT – To know definitions and results that compose the proof of the Euclid's division algorithm theorem, such as the definition of absolute value and the well-ordering principle.

KSM – To establish connections between the Euclid's division algorithm theorem and posterior topics in the Number Theory course, such as linear congruence.

KPM – To know different types of proofs, such as the proof by contradiction that justifies the fact that the remainder is less than the divisor, in proof of the Euclid's division algorithm theorem.

## Context and methods

Our investigation had a qualitative approach. In particular, we adopted the instrumental case study (Stake, 2006) as the research method, looking for information about the subject's knowledge that can be included in the theory about the MTE knowledge. In order to answer the research question, we discuss a classroom episode of a Number Theory course for secondary PMTs, where the MTE aims to present Euclid's division algorithm theorem as well as its proof. The participant Andre, a pseudonym, has Graduation, Master degree and PhD in Mathematics. Since the Master, his research interests lie in Algebra and Geometry. Andre has been teaching at the mentioned university for five years, where he teaches for students of different undergraduate courses, such as Mathematics, Physics and Chemistry. In the period which his classes were observed, Andre was teaching the Number Theory course to undergraduate students in mathematics for the second time in his academic career.

The case study of Andre is part of a larger research study which aims to understand what are the knowledge of MTEs, in particular the ones that teach Number Theory to prospective secondary school mathematics teachers. The results reported in this paper are exclusively based on this participant.

The aforesaid Number Theory course is a 15 week-long course, which is offered once in each semester as a common discipline for prospective teachers and bachelors of mathematics. Furthermore, the PMTs, are oriented to take these classes in the 6th semester of their undergraduate. The course

includes standard contents of a first course in Number Theory, such as divisibility, prime numbers, linear congruence, Diophantine equations and primitive roots.

The data collection occurred in the period between March and July of 2018, in a Brazilian university, comprising class recordings and field notes from the researcher. The classes of this Number Theory course were observed and recorded. Starting from the transcript of the recording of the subject's classes, we divided each class into episodes and chose the episode in which Andre demonstrates Euclid's Division Algorithm Theorem to present and discuss the knowledge revealed by the MTE in this episode, using the MTSK categories.

## Analysis and discussion

### The class episode and its discussion

Andre started the topic of divisibility at the end of the previous class, when he presented the definition and some basic properties of divisibility. The episode that we analyze here is part of a class, which the teacher educator started defining prime numbers. Thereafter he proved the existence part of the Fundamental Theorem of Arithmetic<sup>1</sup>. In the sequence, he proved that there are infinite prime numbers, and he defined Greatest Common Factor<sup>2</sup> as well as he proved some properties<sup>3</sup>. Then, in the episode that follows, the MTE introduces and proves Euclid's Division Algorithm Theorem (EDAT): Considering  $a \in \mathbb{Z}$  and  $b \in \mathbb{Z}_+^*$ , there are unique integers  $r$  and  $q$  such that  $a = bq + r$ , where  $0 \leq r < b$ .

The episode begins with Andre enunciating the EDAT (Figure 1) and drawing the attention of the students to the connections between this result and linear congruence, which will be introduced later in the course. Andre also notes that the proof of the EDAT must be done in two parts: existence and uniqueness. Considering the limited number of pages allowed in this paper, we approach in our analysis the existence proof only. His proof starts considering the set  $S$  of all possible non-negative remainders of the division of  $a$  by  $b$  (Figure 2). Naturally, the first step is to prove that  $S$  is not empty, thereunto Andre discusses with the students to find an integer  $x$  such that the expression  $a - bx$  is non-negative. The conversation continues for some time and the students do not find this particular  $x$ . One of the students apologizes for his incorrect answer and Andre discusses the importance of the students asking questions as well as the need for observing the details of the enunciation of the theorem. Thereafter, Andre provides the sought  $x$  (Figure 3). Since  $S$  is a non-empty set of non-negative integers, thus  $S$  has a minimal element. He denotes this minimum by  $r$  and in the sequence he proves that this element satisfies the theorem conditions (Figure 4). The existence of  $r$  implies the existence of  $q$ .

Andre: Let's see the night star! The Euclid's Division Algorithm Theorem. Then we consider two integers  $a$  and  $b$ . Actually, I'm going to get  $b$  as positive so I do not

<sup>1</sup> Any integer greater than 1 can be written as a finite product of prime numbers.

<sup>2</sup> The Greatest Common Factor of two integer numbers is the largest positive integer number that divides each one of these integers.

<sup>3</sup> Such as "If  $d = \gcd(a, b) \Rightarrow \gcd\left(\frac{a}{d}, \frac{b}{d}\right) = 1$ ".

have problems. Then there exist, and are unique, integers  $q$  and  $r$  such that  $a$  is equal to  $b$  times  $q$ , plus  $r$ , with  $r$  being positive, but strictly smaller than  $b$ . Ok?

**EUCLID'S DIVISION ALGORITHM**

Let  $a, b \in \mathbb{Z}$ , with  $b > 0$ , so EXIST and are UNIQUE  $q, r \in \mathbb{Z}$  such that  $a = b \cdot q + r$  with  $0 \leq r < b$ .

**Figure 1: Euclid's division algorithm theorem written on the blackboard**

The choice  $b > 0$  in the enunciation of the EDAT means that Andre is enunciating a particular version of that result. In the general version, the only condition is that  $b$  to be a non-zero integer. Probably, Andre regards this option to save time, since the proof considering  $b \neq 0$  is divided into more cases. This is an observation that is not mentioned by Andre to the students. He knows how to prove the EDAT (KoT) and he considers  $b > 0$  in order to save time in this class.

Andre: So, in a few classes, which I'm not sure exactly when it is going to be, the division algorithm will be a direct consequence of the congruencies when we study the arithmetic modulo  $n$ . But in this moment we will prove (the EDAT) with the tools that we have.

In the above transcript, Andre establishes a connection between the EDAT and the linear congruence, which is a later topic in the course (KSM). He also establishes a simplification connection in the moment that he states that the EDAT can be seen as a consequence of the modular arithmetic (KSM), and it seems that he attempts to promote this connection in the students.

Andre: It is saying there [pointing to the content in the Figure 1] that my proof must to be written in two parts. Firstly, I must to prove that they exist ( $q$  and  $r$ ) and then I must to prove that they are unique. In this point, we should have understood that the most difficult part (of the proof) is the existence. Regarding the uniqueness, let us suppose that there exist two and we will see that they are the same. Actually, there is no secret about how to prove the uniqueness, but we will begin by demonstrating the existence. OK.

When he states that the proof should be done in two parts (existence and uniqueness), Andre demonstrates knowledge about proof techniques (KPM), and about how to demonstrate the existence and uniqueness of  $q$  and  $r$  (KPM).

Andre: First part. I will consider this set (Figure 2). I take all the sets (integers) of the form  $a - xb$ , where  $a$  and  $b$  are the numbers that I gave at the beginning,  $x$  is an integer and  $a - xb$  is non-negative. OK? I am getting this subset of integers.

Proof. Existence

To consider  $S = \{a - xb \mid x \in \mathbb{Z} \text{ e } a - xb \geq 0\}$

**Figure 2: Set  $S$  written on the blackboard**

In this part, it is possible to identify a heuristic strategy to this particular topic: the choice of an appropriate set  $S$  of natural numbers to approach a property of that set (KPM), namely, the existence of a minimum element in the set.

Andre: I would like to prove that it ( $S$ ) is not empty. Because it is not just a subset of integers. It is a subset of non-negative integers. This is one of my hypothesis, that these integers are non-negative. We know that a non-empty subset of this  $\mathbb{Z}_{\geq 0}$  always admits a minimum. I will play with this. Firstly, I have to prove that it is not empty. To prove that it is not empty, it is enough to show an element in there. Am I right? What element will I get?

To prove that the set  $S$  is non-empty, Andre notes that it is a subset of non-negative integers and thus  $S$  admits a minimal element (KoT). Then, he remembers the fact of all set composed by non-negative integers has a minimum, that is, he refers to the well-ordering principle, which demonstrates that he knows this result (KoT). When he observes that to demonstrate  $S \neq \emptyset$  is necessary just to exhibit one of its elements, Andre gives the way to verify if a set is non-empty (KoT).

Andre: No, that is okay. Do not apologize. Do not apologize, this question allows us (to see) the details, that every detail that is written is important. It is not  $a$  and it is not  $x = 0$ . What is the number that we know that is positive? It is  $b$ . So to get around this, I would put the minus in  $a$  to obtain a positive sum. The only problem is that I do not know if the  $a$  is positive or negative. [...] So I get minus the absolute value of  $a$ . So I have no problem. Because I have the absolute value of  $a$ , I will get  $a$  plus the absolute value of  $a$  multiplied by  $b$ . The  $b$ , yes, it is strictly positive from this one here (initial condition of the theorem). So, this means that there are at least one. Then this value is greater than or equal to zero.

$x = - a $	$\Rightarrow$	$S \neq \emptyset$	admits minimum
$a +  a b \geq 0$			I call it $r \geq 0$

**Figure 3: Proof that  $S$  is non-empty written on the blackboard**

When Andre discusses the importance of the student questions, he exposes his beliefs about the need to perceive and to consider all the conditions of the enunciation theorem. In addition, he demonstrates to understand that this is an aspect to be developed together with his students.

Andre: Then  $S$  is not empty. If  $S$  non-empty is a subset of it ( $\mathbb{Z}_{\geq 0}$ ),  $S$  admits a minimal element. If there is a minimal element, I must to call it of something. I call it by  $r$ . Then let us see if this  $r$  is exactly what I want. OK! First property. The  $r$  which I already know is greater than or equal to zero. Since  $r$  is an element of this form, the minimum of this set (refers to the set  $S$ ), all elements that lie in that set are non-negative, in particular  $r$  is also non-negative. [...] What is the set that I considered? I chose exactly all the integers on the type  $a - xb$  equal to an integer. This means that I am considering all relations such that  $a$  is equal to  $x$  times  $b$  plus one integer. Then, this set  $S$  is chosen exactly to satisfy this relationship here. Am I right? So, I am defining the remainders, I am defining the smallest of the remainders and I want to see that the smallest of the remainders fits here [he refers to  $a = bq + r$ , in the theorem].

After calling  $r$  the minimal element of the set  $S$ , Andre tries to demonstrate that this  $r$  is in the conditions of the theorem. Thus, after showing that if  $r$  is an element of the set  $S$  then  $r \geq 0$  (KoT), Andre intends to prove the fact that the remainder is less than  $b$ , revealing his knowledge of different types of proofs (KPM), such as the proof by contradiction.

I want to prove  $r < b$ .

By contradiction, I will assume that  $r \geq b$ . Then,  $0 \leq r - b = a - bq - b = a - (q + 1)b$ .

I name  $q = x$  such that  $a - bq = r$

$\Rightarrow r - b \in S$

$r - b < r$ .

**Figure 4: Proof that  $r$  is strictly less than  $b$  written on the blackboard**

Andre: It means that this integer here is on the type  $a$  minus one integer times  $b$ . And the integers of the type  $a$  minus another integer times  $b$  are, from definition, the elements of  $S$ . Because also ... they are non-negative. This implies that  $r$  minus  $b$  is an element in  $S$ , because it is an element that is exactly written in the form that the elements of  $S$  were defined and it is non-negative. It satisfies both the conditions, then it is an element within  $S$ . Being an element of  $S$ , and being strictly small than  $r$ , there is a contradiction. Why? Because by definition,  $r$  is the minimum. So there can not exist another element strictly small than  $r$  within the set  $S$ . To come in a contradiction means that the hypothesis that I started all this is absurd. Then, it is impossible  $r$  to be greater than  $b$ , this implies that  $r$  must to be strictly small than  $b$ . Thereat, we finish the existence proof. Why? Because I prove that there are those integers  $q$  and  $r$  that satisfy what I want. I wondered two numbers  $q$  and  $r$  such that  $a$  is equal to  $b$  times  $q$ , plus  $r$ .

This kind of proof by contradiction used by Andre (KPM) is recurrent in algebra. When the thesis is contested, a conflict arises in relation to the minimality of an element.

### Some final comments

In this paper, we analyzed the mathematical knowledge of a mathematician, who teaches for PMTs. The Mathematics Teachers' Specialized Knowledge applies to the analysis of this MTE's knowledge because Andre is teaching mathematics to PMTs. In order to characterize the knowledge of this MTE from the demonstration of Euclid's division algorithm theorem, we find evidence of knowledge of topics, knowledge of the structure of mathematics and knowledge of practices in mathematics. However, this knowledge of the MTE about Euclid's Division Algorithm Theorem is different from the expected knowledge of PMTs and MTs in the same topic, considering that they will not teach this theorem.

The focus is not to evaluate or to prescribe which should be the knowledge of MTEs. Our interest is to investigate which is the existing knowledge in MTEs who participates in our case study, considering the particular Brazilian teacher education context and the role of mathematicians in this context. In this sense, our findings can aid in the elaboration of a model for the specialized knowledge

of MTE, as proposed by Contreras et al. (2017), and may also contribute to the investigations into the knowledge of the MTEs. Furthermore, we propose to investigate indications of what are the fundamental knowledges of these MTEs.

# Emergent model for teachers' conceptions of argumentation for mathematics teaching

Michal Ayalon & Samaher Naama

University of Haifa, Israel

[mayalon@edu.haifa.ac.il](mailto:mayalon@edu.haifa.ac.il) [samaher.yassin@gmail.com](mailto:samaher.yassin@gmail.com)

*In recent years, there has been a growing appreciation of the importance of incorporating argumentation into the mathematics classroom. Whereas considerable research has been done on argumentation, little has specifically focused on teachers' conceptions. This paper presents an exploratory study as part of ongoing research into teachers' conceptions of argumentation for teaching mathematics. Drawing on the literature on argumentation and empirical data, we propose an emergent model, presented as a 5-by-2 construct featuring five types of conceptions across two dimensions: structural and dialogic. This paper illustrates the emergent model at this initial stage of the research using an individual case study of a teacher. The overall aim of the research is to theorize a model that can be used to analyze and characterize teachers' conceptions of argumentation for teaching mathematics.*

*Keywords: argumentation; teachers' conceptions; mathematics teaching*

## Introduction

In recent years, there has been a growing appreciation of the importance of incorporating argumentation into the mathematics classroom. Existing research suggests that participation in argumentation activities that require the student to explore, confront, and evaluate alternative positions, voice support or objections, and justify different ideas and hypotheses, promotes meaningful understanding and deep thinking (Asterhan & Schwarz, 2016). This view is reflected in recent educational reform documents all over the world, and in Israel in particular, that underscore argumentation as one of the important goals for students. However, argumentation in the mathematics classroom is not yet commonplace (e.g., Bieda, 2010). Recently, there has been considerable research dedicated to argumentation; however, little of that work has specifically focused on teachers' conceptions of argumentation (Ayalon & Hershkowitz, 2018; Staples, 2014). Considering the fact that teachers' conceptions impact the way in which this key practice is implemented in the classroom, there is a strong need to learn what characterizes them. This paper addresses this need. It presents an exploratory study as part of ongoing research into teachers' conceptions of argumentation for teaching mathematics. Drawing on the literature on argumentation and empirical data, we propose an emergent model, presented as a 5-by-2 framework comprising five categories of conceptions of argumentation for teaching mathematics across two dimensions: structural and dialogic. This paper illustrates the emergent model at this initial stage of the research.

## Theoretical Background

### Argumentation

There are diverse definitions of argumentation in the education literature. A commonly accepted definition is that of van Eemeren and Grootendorst (2004) who argue that argumentation is “a verbal, social, and rational activity aimed at convincing a reasonable critic of the acceptability of a standpoint

by putting forward a constellation of propositions justifying or refuting the proposition expressed in the standpoint” (p. 1). According to this definition, argumentation entails generating claims, providing evidence to support the claims, and evaluating the evidence to assess their validity. It posits argumentation in a social context and, if incorporated in classroom discourse, affords a venue for the articulation and critical evaluation of alternative ideas, eventually supporting collaborative knowledge construction (Asterhan & Schwarz, 2016). Argumentation that “balances between critical reasoning and collaborative knowledge construction” (Asterhan & Schwartz, 2016, p. 167) is considered to be productive for learning (Felton, Garcia-Mila, & Gilabert, 2009).

Following these descriptions, the present work considered argumentation as having two important meanings – structural and dialogic (McNeill et al., 2016). The structural meaning of argumentation focuses on the aspect of discourse in which a claim, presented as an idea, conclusion, hypothesis, solution etc., is supported by an appropriate justification which, in our case, represents the types of justifications that are valued within the mathematics community. The dialogic meaning regards argumentation as the interactions between individuals when they attempt to generate and critique each other’s ideas. This meaning aligns with the common view of mathematics as a social enterprise whereby mathematicians are part of a community with established norms of argumentation for advancing mathematical knowledge.

### **Teaching for argumentation**

Mathematics teaching that encourages argumentation provides students with opportunities to take an active part in both structural and dialogic meanings – to construct arguments, share, consider others’ ideas and critically evaluate their validity (Ball & Bass, 2003). Such teaching requires the teacher to make sense of students’ ideas and interactions, identify and evaluate the strengths and weaknesses, promote adherence to standard disciplinary criteria for determining the truth of a claim, encourage students to elaborate their thinking, and lead them to listen to each other, critique and question ideas (Nathan & Knuth, 2003). It entails the teacher’s drawing on various resources, such as the mathematics involved, student thinking, socio-cultural background, affect, and curriculum-related aspects (Ayalon & Even, 2016; Ayalon & Hershkowitz, 2018; Staples, 2014). As noted above, argumentation in the mathematics classroom is rare (e.g., Bieda, 2010), which suggests that teaching for argumentation is perhaps challenging. Whereas research on argumentation is rapidly growing, little research specifically focuses on teachers’ conceptions in the context of argumentation.

This study draws on existing research to propose a preliminary working definition for mathematics teachers’ conceptions of argumentation for mathematics teaching, with the intention of further developing this definition as a research goal. The use of ‘conceptions’ refers to both knowledge and beliefs, according to Thompson (1992), who described teachers’ conceptions of the nature of mathematics as their combined knowledge and beliefs pertaining to the discipline of mathematics. Following this definition, the present study focuses on teachers’ conceptions of argumentation in mathematics teaching, under the assumption that in order to develop teachers’ instructional practices for argumentation, we need to better understand their conceptions. In particular, we focus on teachers’ conceptions as they relate to both the structural and dialogic aspects of argumentation.

## Methodology

The data for the overall research were collected through observations of lessons and semi-structured interviews which preceded and followed the lesson observations. For this paper, we focused on data obtained from the first part of the interviews conducted prior to the lesson observations, in which the teachers were asked to express their views on argumentation for teaching mathematics and to provide examples of argumentation, as manifested in their own teaching.

### Research participants

Eight middle-school mathematics teachers, each having more than five years of teaching experience, participated in this study. The decision to focus on this particular school population stemmed from the emphasis placed on argumentation in the middle-school curriculum in Israel.

### Data collection

The data used for this paper consisted of individual, semi-structured interviews with the teachers. The interview lasted approximately one hour. During the interviews, the teachers were presented with a written quote from the national mathematics curriculum that reflects the importance ascribed to students' involvement in argumentation activity in the mathematics classroom. According to this quote, one main goal of the curriculum is that students will engage in justifying their claims, communicate them to others, and critique their own and their peers' arguments. The teachers were asked: (1) What do you think about this quote? Do you agree or disagree? Why? (2) What strategies, if any, do you use in your classroom to achieve this goal? (3) What have you found supports or hinders you in achieving your goals? The teachers were urged to provide detailed responses as well as instances from their own classroom. The interviews were audio-recorded and subsequently transcribed.

### Data analysis

We combined directed content analysis and inductive content analysis (Patton, 2002). Directed content analysis included a classification of teachers' statements about argumentation in mathematics teaching into one of the two aspects of argumentation: structural or dialogic. The structural aspect dimension included discourse pertaining to elements of arguments, such as claims and justifications and what counts as an appropriate justification in class. The dialogic aspect dimension included discourse associated with students' interactions when generating and critiquing arguments. We then used inductive content analysis for devising categories for the two dimensions. During this phase of analysis, we first identified initial categories based on some of the data collected for a particular teacher. We then refined and expanded the initial categories based on more data collected for the same teacher. Finally, the devised categories were refined by the analysis of data collected for all the participating teachers. This process resulted in five categories of teachers' conceptions of argumentation: (1) what is argumentation; (2) teaching strategies for argumentation; (3) mathematical task characteristics; (4) student characteristics; and (5) socio-cultural characteristics. We ultimately received a 5-by-2 framework featuring these five categories for each of the two dimensions: structural and dialogic.

In this paper, we provide examples that illustrate the way in which several of the framework's different components were devised based on the teachers' discourse about argumentation in teaching. The

examples of categories are taken from an interview with one teacher named Adam (pseudonym), as we found his interview rife with illustrations for various categories. Note that each category was identified in other teachers' interviews as well. Naturally, one citation may refer to more than one aspect of argumentation.

## Findings

Adam is a middle-school teacher (grades 7-9) with 25 years of experience in teaching mathematics. He serves as the mathematics teaching coordinator and is considered by his colleagues to be a leading teacher in his school. When asked for his opinion of the quote taken from the curriculum with regard to the importance of engaging students in argumentation, he replied:

The things said in the quote are very important in the learning of mathematics. This [argumentation] helps to promote students' understanding of the material; the teacher can understand, identify and emphasize the thought process of each student who raises claims in class and justifies his or her answer [1-1] ... Also, critiquing others' arguments helps students to develop their mathematical thinking [1-2].

This initial response from Adam implies *what argumentation means* to him. His response relates both to the structural aspects of argumentation and to its dialogic aspects. He mentions claims and justifications (structural, 1-1), alongside critical assessment of one another's arguments (dialogic, 1-2). According to Adam, this activity allows the teacher to learn about students' thought processes, and helps to develop students' mathematical understanding. When asked how he uses argumentation in his classes, he replied:

In my classes, I always use argumentation activities. The students raise ideas, explain, and bring justifications [2-1]. Different solutions for the same problem arise, and a fruitful dialogue develops in which the students explain their solutions, try to convince others, and find mistakes in others' solutions, and critique each other [2-2]. The students listen to each other and give criticism politely and respectfully [2-3]. This atmosphere encourages students to participate in math classes, so that the student feels like a central part of the lesson [2-4]. Also, a student who correctly justifies her/his solutions will feel greater self-confidence [2-5].

Adam's answer informs us more of *what argumentation means* to him, both from a structural perspective (2-1) and a dialogic perspective (2-2, 2-3). This answer expands on his previous response by relating, also, to persuading others of the correctness of one's views, and to assessment that is not only critical, but also respectful (2-3). There is mention here of *class norms* of respectful critical dialogue (2-2, 2-3). He also mentions *students' emotional characteristics* – student engagement and the student being in the “center” – that are connected to the student's participation in dialogue (dialogic, 2-4) and to self-confidence stemming from justification of a solution (structural, 2-5). When he was asked to give more details regarding the way in which he encourages argumentation activities in his class, Adam said:

In general, I try to give the students open, multiple-solution tasks [3-1], and give students space to express themselves and to present their solutions and examine them together with the rest of the class, and reach agreements together [3-2]. For instance, tasks involving word problems, or problems that involve finding generalizations – there are students who manage to come up with various hypotheses and solutions, some correct and some not, and there are students who struggle

[with the challenge] [3-3]. What's important is that when we work with these tasks in my class, it always turns into a mathematical discussion [3-4] which the students enjoy [3-5], and in which students listen to each other's solutions and explanations and critique them, try to challenge their arguments and also to defend arguments [3-6]. When I give them problems to solve individually, my sense is that the students feel like it's a competition, who will find a solution first and give a correct justification [3-7] - after all, I don't accept answers without a clear, written explanation and mathematical justification [3-8] - and who will present their solution to the class [3-9] ... I mean "competition" in a positive sense.

In Adam's answer, he notes the *characteristics of mathematical tasks* that encourage argumentation in class. Open, multiple-solution tasks serve Adam's purposes when it comes to the dialogic activity he mentioned earlier [3-1]. Here, Adam also discusses *students' skills* in coming up with hypotheses and various methods of solving (3-3). Two additional characteristics of the dialogic aspect of argumentation, which Adam did not mention earlier, come up in the context of working with these types of tasks: one relates to students working towards consensus (3-2); the other relates to defending one's arguments (3-6). This response also makes note of the *socio-cultural norms* that pertain to argumentation activity, in Adam's mention of mathematical dialogue: "when working with these tasks in my class, it *always* turns into a mathematical discussion" (3-4), and in the expectation in his class for a justification of the claims (structural, 3-9). He also mentions the norm of writing arguments clearly (3-8). Adam previously mentioned students' engagement in argumentation activities; here, he adds a competitive but friendly, good-spirited atmosphere between the students, challenging who will solve the problem first and present the solution, with its justification, to the whole class (3-9). He also mentions enjoyment (3-5).

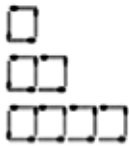

Adam was then asked to give an example of a hypothetical implementation of an argumentation activity in his class. He chose to talk about employing the known "match train" task, which includes an examination of concrete cases involving small numbers (1, 2, and 3 wagons) and then the formation of an algebraic expression. Figure 1 presents part of a script Adam wrote down for an imaginary dialogue in his class focused on finding the number of matches needed for any number of squares.

When discussing his script, Adam emphasized: "I took into account ways in which students' thinking about building generalizations might be incorrect, such as employing empirical methods or using invalid proportional reasoning" [4-1]. He also referred to his approach of "prompting as many arguments as possible" [4-2] as well as "bringing students' ideas to the class for judgment" [4-3], while "emphasizing important ideas given by students, such as the use of counterexample" [4-4]. In addition, Adam said: "I would use various strategies for providing students with scaffolding in generating arguments [4-5]. For example, by using real matches to help students develop a sense of the situation [4-6], suggesting counterexamples to use in refuting students' claims [4-7] ... and using a table of values to support students' efforts to reach a generalization and to identify invalid claims, such as the one suggested by student #3" [4-8].

Adam's concrete example of implementation of a task provides us with more ideas about the way he conceives argumentation: First, in terms of the structural aspect, with claims and justifications requested in class and distinguishing between accepted and unexpected justifications (4-1). Secondly, in terms of the dialogic aspect, his approach here is very similar to the one he raised with regard to argumentation in his earlier responses (4-2, 4-3). In this response, we can also see Adam referring to

*student characteristics* related to common ways of thinking (4-1), along with a reference to *teaching strategies* associated with promoting argumentation, such as prompting students' dialogue (4-2, 4-3), explicating important mathematical argumentation ideas in class (4-4), and providing students with scaffolding through the use of various examples (4-7), representations (4-8) and tools (4-6).

Let's make "trains" from matches.

S1: I will continue counting.  
 S2: It is not an efficient method.  
 Teacher: Do you agree? If we would like to build a train with 1,000 wagons, will you count the number of matches?  
 Students: no, it is too hard.  
 Teacher: So what will we do?  
 S3: We will multiply the number of matches by four.  
 Teacher: Students, what do you think about it?  
 S4: I think it is not okay. If we have for example two squares we will need 7 matches and not 8.  
 Teacher: Very good argument. We have here a counterexample for the claim that the number of matches is the number of squares multiplied by four.  
 S5: For each additional wagon we need more three matches.  
 Teacher: What do you think class?  
 Students: yes yes  
 Teacher: Let's draw on the board... Follow me and think about the generalization...

**Fig. 1** A part of the script Adam wrote for an imaginary dialogue in his class

Overall, the above statements from Adam's interview illustrate the way in which several of the different components of the framework were devised. Figure 2 presents the emergent framework for teachers' conceptions on argumentation for mathematics teaching. Several of the categories were identified in Adam's statements as presented in this paper, and therefore appear in the model, accompanied by their indexes in brackets. Other categories were not illustrated in this paper; however, they will be further elaborated upon in the conference presentation.

Mathematics teachers' conceptions of argumentation		
	Structural aspects	Dialogic aspects
What is argumentation?	<ul style="list-style-type: none"> <li>• Elements of argumentation: claims and justifications (1-1, 2-1, 4-1)</li> <li>• Types of justifications valued (4-1)</li> </ul>	<ul style="list-style-type: none"> <li>• Students raising different point of view (2-2, 3-2, 4-2)</li> <li>• Students listening critically to each other's arguments (1-2, 2-2, 4-3)</li> <li>• Students defending their ideas (3-6)</li> <li>• Students attempting to convince others of their opinion (2-2)</li> <li>• Students listening to each other respectfully (2-3)</li> <li>• Students working towards consensus (3-2)</li> </ul>

<b>Teaching strategies</b>	<ul style="list-style-type: none"> <li>• Encouraging and scaffolding students' justifications (e.g., through questioning, using concrete examples and tools) (4-5, 4-6, 4-7, 4-8)</li> <li>• Encouraging self-evaluation of claims</li> <li>• Providing criteria for justification</li> <li>• Explicating important mathematical argumentation ideas (4-4)</li> <li>• Requiring written justifications (3-8)</li> </ul>	<ul style="list-style-type: none"> <li>• Encouraging students to present different points of view (4-2)</li> <li>• Encouraging students to respond critically to each other's arguments (4-3)</li> <li>• Giving value to students collaborating on, generating and critiquing arguments</li> </ul>

**Fig. 2** Emergent model for teachers' conceptions of argumentation in teaching mathematics

## Conclusion

This paper presented an exploratory study as part of ongoing research into teachers' conceptions of argumentation in the teaching of mathematics. It proposed an emergent 5-by-2 framework comprising five categories of conceptions of argumentation for teaching mathematics across two dimensions: structural and dialogic. The study opened with a presentation of the theoretical distinctions related to argumentation, focusing on structural and dialogic aspects as the main dimensions of argumentation (McNeill et al., 2016). The empirical investigation of the teachers' discourse on argumentation in their teaching resulted in five categories of teachers' conceptions of argumentation: (1) what is argumentation, (2) teaching strategies for argumentation, (3) mathematical task characteristics, (4) student characteristics, and (5) socio-cultural characteristics. These categories reflect the complex process of establishing argumentation in the mathematics classroom and the roles that teachers need to fill in order to facilitate argumentation (Ayalon & Even, 2016; Ayalon & Hershkowitz, 2018; Mueller, Yankelewitz, & Maher, 2014; Yackel, 2002), and adhere to notions of productive argumentation that promotes learning (Asterhan & Schwarz, 2016).

This is the beginning of learning about mathematics teachers' conceptions of argumentation in the mathematics classroom. We intend to continue our research, basing the work on the categories

developed in this paper. First, the model will be applied to characterize each participating teacher's conceptions. Second, since the research literature shows that teachers' declarative conceptions can be different from those realized in their actual teaching (e.g., Lev-Zamir & Leikin, 2013), we intend to use the model for analyzing the teachers' lessons, and for ascertaining the relationships between teachers' declarative conceptions and their conceptions 'in-action' with special attention devoted to argumentation. The analysis will also search for new categories, in order to refine the model to be used to analyze and characterize teachers' conceptions of argumentation in the teaching of mathematics.

*The study attempted to investigate the ways a prospective teacher, Elif, responded to contingent moments in her teaching practice. In addition, her perceptions regarding changes in the nature of the tasks based on the students' unanticipated thinking after the teaching were examined. Elif attended to a two-hour class of teaching seminar in which categorizations of mathematical tasks were presented. Then, during her enrollment in teaching practicum course, she taught a lesson on algebra by considering the categorization of the tasks. The lesson plan, her video record of teaching, semi-structured pre and post interviews were analyzed based on contingent trigger categories and kinds of teachers' responses to them and tasks during the phase of selecting, enacting and revising were analyzed based on its cognitive demand. Results showed that the contingent moments lead her to reanalyze the content and implementation of the designed tasks for further teaching.*

## Introduction

A mathematical task (i.e. a problem or a set of problems) is “a classroom activity, the purpose of which is to focus students' attention on a particular mathematical idea” (Stein, Grover, & Henningsen, 1996, p. 460). The teacher's pedagogical knowledge in planning lessons has a crucial role in the way mathematical tasks are selected and implemented (Stein, Grover & Henningsen, 1996). Thus, designing tasks based on students' understanding and identifying students' ways of thinking during task implementation as parts of teachers' knowledge are important abilities for effective teaching (Fernande, Llinares and Valls, 2010). Hence, as Chapman (2013) stated, during practice teachings, focus be placed on pedagogical knowledge regarding the nature of task.

In the context of task implementation, eliciting students' ways of thinking has become an important skill for teachers during practice teachings. Rowland and Zazkis (2013) concluded that “a teacher's responses to problematic contingent moments that arise in teaching mathematics are fundamentally dependent on their mathematical knowledge, which prompts and guides pedagogical implementation” (p. 151). It is a fact that due to the nature of the learning environment, which is dynamic and complex, teachers as well as novice teachers encounter many challenges in responding to student needs (Foster, 2014). Hence, teachers should be well prepared for such potential contingent situations and moments for the following teaching practices (Rowland, Thwaites, Jared 2015). Thus, the present study aimed to reveal the novice teacher's knowledge regarding the contingencies so that mathematics teacher educators can have a better understanding of novice teachers' pedagogical knowledge (Liston, 2015). Hence, the study initially attempted to examine how a preservice teacher responded to these contingent moments.

Not only declining or maintaining the cognitive demand level, but also transforming tasks with lower cognitive demands into high-level tasks are closely linked to students' ways of thinking and teachers' decisions at contingent moments. At a more detailed glance, teachers' decisions regarding the nature of a task and sequences of tasks are shaped by students' opinions and their ways of thinking at the moment that is related to active facet of contingent knowledge. Moreover, proactive aspect (Hurst, 2017) of it includes teachers' planning of task design where they seek to address students' misconceptions. Hence, eliciting students' ways of thinking and unexpected responses might ensure effective task implementation and design. In this respect, it is believed that experiencing 'Contingency' instances may provide novice teachers with opportunities to improve their pedagogical knowledge (Rowland, Thwaites & Jared 2015) by transforming tasks into high-level tasks or maintain tasks' cognitive demand. Hence, the second aim of the study was to explicate how these contingent moments guide teachers in thinking about the nature of the tasks implemented. This is important since research needs to identify how the opportunity of contingent moments and knowledge in features of the level of the tasks support teachers' ways of altering tasks in following teaching practices. Thus, the research questions of the present study were stated as follows: (1) How does a novice mathematics teacher respond to contingent moments during her teaching of algebra? (2) How do contingent moments help the preservice teacher to reconsider the nature of the task for further teaching?

### **Theoretical Framework- Knowledge Quartet Model (KQ)**

An empirical framework called as Knowledge Quartet developed by Rowland, Huckstep and Thwaites (2005) has been used to assess and develop both pre-service and in-service mathematics teachers' mathematical knowledge during planning and teaching. It comprises four main units; namely, foundations, transformation, connection and contingency. The last component of the knowledge quartet, *contingency*, is described as 'the "opposite" [their emphasis] of planning – to situations that are not planned and that have the potential to take a teacher outside of their planned route through the lesson' (Rowland and Zazkis, 2013, p. 139). Contingency is concerned with a teacher's ability to make convincing, meaningful responses to unanticipated student answers, questions and statements. "Responding moves", similar to *contingency*, are regarded as key moments in organizing a lesson (Brown & Wragg, 1993). Based on the model, contingent moments are associated with the codes of "responding to students' ideas; deviation from agenda; teacher insight; (un)availability of resources" (Rowland, Turner & Thwaites p. 4). Therefore, in this study, we first identified contingent moments in the video recording of the pre-service teacher's instruction and then analyzed whether or not the teacher attended to those moments, and how she reconsidered the nature of the tasks based on those instances.

Within the context of the mathematical tasks, the Mathematics Tasks Framework characterizes three phases through which tasks pass: first, as they are in the curricular materials; next, as tasks are set up by teachers; and last, as they are applied by students in the classroom (Stein, Grover and Henningsen, 1996). All these are believed to have an important impact on students' learning process. The cognitive demand of mathematical tasks emphasized in the second phase of the framework refers to "the cognitive processes students are required to use in accomplishing [tasks]" (Doyle, 1988, p. 170). It is classified into four categories, which are memorization, procedure without connection, procedures with connection

and doing mathematics (Stein et al., 2000). Tasks with a low cognitive demand (memorization and procedure without connection) require students to memorize facts, rules and procedures without relational and conceptual understanding and do not lead students to engage in high-level mathematical thinking, such as problem solving, reasoning, connection and critical thinking (Stein & Lane, 1996). On the other hand, mathematical tasks with a high level of demand include multiple entry points rather than a single answer. In other words, high level tasks entail explorations of mathematical ideas by thinking critically and reasoning.

Although researchers emphasized that the high-level tasks are key to acquiring mathematical ideas (Stein, Grover, & Henningsen, 1996), tasks themselves, even high-level ones, may not result in high level understanding. At that point, the role of the teacher during the preparation and implementation of mathematical tasks have emerged as a crucial aspect in teaching mathematics conceptually (Doyle, 1988). Indeed, teachers should be responsible for changing the cognitive demand of tasks during classroom implementations (Smith, Grover & Henningsen, 1996). Hence, teacher knowledge could be regarded as one of the important factors impacting teachers' way of altering task features to meet student needs.

## **Methods**

### **Context and Participants**

The case study research methodology is used to respond to “how” or “why” questions in detail (Yin, 2013). Since the main aim of the study was to analyze and reflect on complex classroom practices, the responses to the research questions of the study were sought by utilizing the single case study methodology. In a project, six novice teachers were selected based on their willingness to participate in the study and on their high-level of achievement in the teaching method courses. The participants were provided with a (two-hour) seminar on the Smith and Stein's categorizations of mathematical tasks. The seminar was held to familiarize them with each level of the cognitive demand of the tasks. It was believed that this familiarity would enable them to critically analyze the features of the tasks with respect to how students think and present mathematical opinions. Subsequent to the seminar, they were expected to prepare a lesson plan including tasks with a low or high level of cognitive demand. Elif, a novice mathematics teacher, volunteered to teach a class; therefore, Elif's lesson was selected for the present case study.

The pre-service elementary mathematics teacher, Elif, was in her fourth year at a public university in Turkey. Thus, Elif had completed Teaching Mathematics Method courses and Practice Teaching I course aiming at providing an opportunity to observe teachers' the way of teaching and student learning. In addition, she was experiencing the teaching for the course of Practice Teaching II (practicum). She planned lessons to meet the requirement of Practice Teaching II (practicum) and we focused on one of her lessons.

### **Data Collection and Analysis**

The lesson plan, video recordings of her lesson and the audio-record of the semi-structured pre- and post-interviews were used as data sources. The pre-interview lasted 50 to 70 minutes in a one-on-one setting

to determine her perceptions regarding the nature of the tasks selected for the lesson and her opinions regarding unexpected ways of student thinking related to the tasks. After her lesson, she was asked to observe the video of her teaching by using the classification features of cognitive demand tasks as a guide. Finally, we performed a semi-structured post-interview to gain information regarding her views on the way she responded to contingencies and redesigning the task. Sample questions from the post-interview are as follows: “How would you deal with that response?” The tasks as data in the processes of planning, acting and revision were analyzed using the cognitive demand levels in the mathematics task analysis guide (Stein et al. 2000). In addition, the lesson episodes including the implementation phase of the first and second tasks were transcribed and then analyzed based on the contingent trigger categories of Rowland et al. (2015) and different kinds of teachers’ responses to them.

### Overview of Elif’s lesson

Elif taught algebra for 7<sup>th</sup> grades. The learning outcome of the lesson required learners to be able to describe how two variables having linear relationship with each other vary by using table, graphic and equations. There were 22 students in the class, 12 boys and 10 girls. They were seated at tables in front of the board and Elif stood at the board and walked around the seats for some time. The lesson started with a task at the level of ‘memorization’. More specifically questions: “what is the meaning of linear relationship?”. Then Elif continued with the second task which was related to the relationship between two variables varying together designed at the level of ‘procedures without connection’ provided below.

Interpret the changes in volume of the beaker and time.

Figure 1: The Second Task

### Findings

Contingent moments emerged during enactment of the first task and Elif’s responses to the moments provided as follow:

#### Linearity: Speed, Time and Position

After Elif presented the first task to the class, three or more students defined the linearity between two variables and then two of students mentioned speed and time. She accepted the responses and got students to think of the relations among those variables, namely time, speed and distance, as in the following conversation:

Elif: Yes, speed increases as time increases, right? Or is speed constant?

Student 1: Speed can change; for instance, the speed can be 61 km/h during half of the distance. Then, the car can go at 59 km/h during the other half of the distance. Then, the speed will be 60 km/h and [hence] constant.

Elif: Do you think that speed is constant as time increases, or speed increases as time increases. Which one?

Student 1: Overall, the speed did not change.

However, some responded by saying “Constant”.

Elif: Now consider that time increases, and speed is constant. Only one variable is changes. Yes? So, what does linear relationship mean?

Then she drew a graph of time versus speed (speed is constant) and explained that speed had one value as time increased. Then she asked a question “Is this a linear relationship?” by pointing to the graph. One student responded by saying, “it [the value for y-axis] might be distance.” Then she drew the graph of time versus distance when speed is constant, and she continued to say:

Elif: If we go back to the speed example, should the speed increase in time? How does speed change? Is it constant, increases constantly or how?

Student 2: It should be [increasing] at certain intervals. 60,120,180...

Student 3: Certain ratios

Elif: Yes, another example?

Student 1: [For instance] the pupil read 10 pages of a book on the first day, and on the second day the pupil read 20 pages of the book?

Elif: [By interrupting the student’s speech] If I said there is a linear relationship, it should be increased by certain ratios or number. [By pointing to the second speed versus time graph] Do you understand now why I cannot say that there is a linear relationship?

This contingent moment related to confusion in the concept of constant rate of change arose based on students’ responses to the first question and students’ spontaneous responses during the discussion. The response of Students 1 led Elif to hold a discussion on the linearity of variables in the context of time and distance. During the post-interview based on the first task, Elif stated that she had not expected such an example as time and speed instead of time and distance; hence, she was confused.

Elif channeled students towards considering the one possible correct example that as time increased, distance also increased in the condition when speed was constant. Thus, this might indicate that she acknowledged the opinion of Student 1 regarding the ‘linear relationship between the average speed (speaking of two constant speeds) and time’, but it was ignored, perhaps because Elif did not understand the student’s idea and its relationship with linearity or she was challenged in elaborating the misconception. During the discussion, despite Elif’s directions, some students responded to the question by saying that the relationship between the time and speed was linear. She did not attend to those responses either, and she stated in the post-interview that her focus was solely placed on receiving distance versus time as a correct answer from the students. In this regard, it could be inferred that Elif focused on receiving the same answer that was on her own mind and was not open to any other alternative response.

## Linearity: Graphs

The second contingency and Elif's response to it was as follows:

Student 1: [The line in] the graph must pass through the origin. Right?

Elif: No, it is wrong, in our examples there can be a starting point.

Student 1: How?

This unanticipated situation was related to the student's tendency to create a graph with a line passing through the origin for linearity. The teacher addressed the student's unexpected opinion by correcting it. However, the opinion was not discussed by using any representations. She presented the reasons for her action during the post-interview by saying she did not know how to combine the situation with their graphs, and thus, judged the idea as being unworthy for discussion in the class. The changes in the first task recommended by Elif are presented under the next heading.

## Perceptions on Modifying the Task

Two contingent moments and Elif's reactions to those moments have been described above. During the post-interview, Elif suggested changes in the properties of the task, in its sequence, and the time allocated for the task, as can be observed in the following conversation:

Interviewer: If you had the chance to apply these tasks, how would you deal with that response?

Elif: The task: "Consider that a bus arrives at each station at each station at exactly the same time duration and the distance between each station is the same. Explain the relationship among the variables (distance, time and speed) in this situation". Then "If my speed or distance is not zero at the beginning, could we speak of similar relationships among the determined variables? Justify your examples by drawing graphs [of the quantities]".

As can be understood from the above conversation, the teacher had to ask follow-up questions to get students to consider the situation. Moreover, she had to focus on representation of the variables graphically. Moreover, Elif underlined the fact that the first and the second tasks, which were at the level of 'memorizations' and 'procedures without connection', respectively, could be merged, and there was no need to have students do the second task since the concepts of time, speed and distance were great an opportunity for discussion. By integrating the contingent moments and the properties of tasks with a high cognitive demand level, the teacher wanted to redesign the task requiring a higher level of cognitive effort and students to use representations. With the assistance of the guide, she critiqued her tasks based on whether the revised version was coherent with respect to the properties of the tasks with a high level of cognitive demand and different from the properties of the ones with a low level of cognitive demand. For instance, she believed that she expected students to become aware of the meaning of the linear relationship in the context by leading them to use appropriate representations instead of giving them an algorithm or memorized facts (the definition of linear relationship). Thus, the task was coded as one with a higher-level demand.

## Discussion

The present study yielded the emergence of two contingent moments associated with *trigger type 1: responding to students' ideas*, proposed by Rowland et al. (2015). The moments were related to students' incorrect examples for linearity that stemmed from their misinterpretation of the degree of change and students' tendency to sketch graphs of variables having linear relationships with a line passing through the origin. During the pre-interview, Elif did not mention these students' possible opinions since she believed that low level tasks required limited cognitive demand and were solved by means of utilizing procedures, and she expected the students to give the definition of linear relationships as the correct answer. As the students presented different ideas related to linearity during the implementation of the task, the teacher was not able to effectively monitor and reflect different student ideas. Hence it could be stated that she had a perception that cognitive demand of a selected task did not change during the enactment of the task.

The findings related to the teacher's response to these unanticipated moments revealed that Elif became engaged in some of the students' unexpected answers, but she directed students to think only of the time versus distance example. In addition, during the classroom discussion, Elif did not attend to students' ideas; however, focusing on these ideas could have resulted in students' conceptual understanding of the mathematical idea (linearity). Combining this finding with the claim that the nature of teaching in real settings is dynamic and complex, we concluded that as a novice teacher, she was incapable in handling these moments occurring in the classroom (Foster, Wake & Swan, 2014) and could not make use of the opportunity of the unanticipated instances. For this reason, it could be maintained that she might have an answer-oriented approach that teachers rely on short recall questions and leading questions to guide students to the solely correct answers (Moyer & Milewicz, 2002) although she tried to increase the cognitive demand of the task by drawing the graphs. It could be claimed that her mathematics knowledge for teaching, a crucial factor for task implementation (Stein, et al, 2000), was weak since she could not give meaning to mathematical procedures (e.g. Charalambolous, 2010).

Although Elif was not able to orchestrate the discussion and she lacked in responding to unanticipated moments occurring during her teaching, she emphasized a need to change the nature and structure of the task addressing the second research question. In other words, these moments presented an opportunity for her to become aware of the different ways of student thinking that is concerned with proactive facet of contingent knowledge. Hence, it could be deduced that Elif benefitted from her experience (Rowland, Thwaites, Jared 2015). Moreover, the guide for task classifications was beneficial for redesigning the task for further teaching. Besides, the paper particularly provided insight into the fact that contingent moments triggered preservice teachers towards improving their low-level tasks and reconsider the sequences of the tasks, and this may, in turn, enhance their knowledge of mathematical tasks. In the light of the study, it could be claimed that more exposure to contingency moments through video clips by knowing the classifications of the mathematics tasks within the scope of the teaching practice courses can prepare pre-service teachers to actual classroom environments. In conclusion, the study contributed to the literature with information regarding the impact of contingent moments on the implementation of low-level tasks. However, analyzing data of merely two low level tasks and basing the study on the

reflections of one pre-service teacher could be regarded as the limitations for the study. Hence, further studies are needed to portray the relationship between unanticipated student responses and the ways that pre-service teachers achieve high cognitively level tasks.

# Using the Knowledge Quartet to analyse interviews with teachers manipulating dynamic geometry software

Nicola Bretscher

UCL Institute of Education, London, UK; [n.bretscher@ucl.ac.uk](mailto:n.bretscher@ucl.ac.uk)

*This paper reports the use of the Knowledge Quartet as a tool for analysing mathematical knowledge in teaching arising in interviews with four secondary mathematics teachers based around a pre-configured GeoGebra file involving circle theorems. This research was part of larger doctoral study, where the Knowledge Quartet was chosen as a means of providing a fine-grained analysis focusing on mathematical knowledge in teaching. The sub-codes of the Knowledge Quartet were originally grounded in classroom observation and have been rarely exemplified through situations involving teachers use of technology. A tension is identified in applying the Knowledge Quartet to an interview situation involving technology centring around the sub-code 'adherence to textbook', with wider implications for how the framework is applied to situations involving teachers' use of (technological) tools.*

**Keywords:** Knowledge Quartet, teacher knowledge, technology.

## Introduction

Using digital technologies, such as the dynamic software package GeoGebra, can place significant demands on teachers' mathematical knowledge (Laborde, 2001) and hence provide opportunities for making such knowledge visible and available for exploration. The research reported in this paper forms part of a larger doctoral study investigating mathematical knowledge in teaching using technology. The Knowledge Quartet (Rowland et al., 2005) is a widely used and influential framework for analysing mathematical knowledge in teaching, (see previous TWG20). The framework is composed of four supra-categories Foundation, Transformation, Connection and Contingency, generated by grouping 18 sub-codes representing prototypical classroom situations where mathematical knowledge for teaching is called upon, derived from analysis of classroom observations. The strengths of the Knowledge Quartet, in terms of this study, lie in the framework's focus on mathematical knowledge for teaching and the grounding of its codes in classroom observation, thereby maintaining strong face and content validity. For these reasons, the Knowledge Quartet was chosen as a means of providing a fine-grained analysis focusing on mathematical knowledge in teaching, as opposed to technology-focused frameworks such as the Technology Pedagogy and Content Knowledge (TPACK) framework (Mishra & Koehler, 2009). In addition, research on the importance of variation to structure sense-making (Marton & Booth, 1997; Watson & Mason, 2006) suggests the code *choice and use of examples* (Transformation) may be advantageous as a tool for analysing mathematical knowledge for teaching using technology in the context of the semi-structured GeoGebra interviews, since dynamic variation is central to such software (Leung & Lee, 2013).

The sub-codes of the Knowledge Quartet have rarely been exemplified through situations involving teachers use of technology. One such instance of a situation involving teachers' use of technology resulted in the addition of a new sub-code *responding to the (un)availability of tools and resources*

to the Contingency category of the Knowledge Quartet (Rowland et al., 2015). Hence extending the use of the Knowledge Quartet to analyse situations beyond its original evidence-base may provoke further refinement of the framework. This paper seeks to address the following research question:

What tensions are exposed in using the Knowledge Quartet as a tool for analysing the mathematical knowledge in teaching arising in interviews based on a GeoGebra file involving circle theorems?

This paper also relates to a broader concern in TWG20 in CERME11 (e.g. Montes et al. (2019, February); Codes et al. (2019, February)) of investigating how tasks, in this case manipulating a GeoGebra file on circle theorems, can be used to explore, support and develop mathematics teachers' knowledge and what the implications for teacher education may be. The next section provides the theoretical background underpinning the study, by first setting out an overarching perspective of teachers' knowledge being distributed (Hutchins, 1995) e.g. across tools and then describing the Knowledge Quartet in more detail. In the following sections, analysis of interview data reveals a tension in applying the Knowledge Quartet, centring around the sub-code *adherence to textbook*, with wider implications for how the framework is applied to situations involving teachers' use of (technological) tools.

## Background

Hutchins (1995) argues that conceptualising cognition as distributed assumes that cognition is not only a property of an individual person, but also occurs through human interaction with artefacts and other humans. In particular, he argues that cognition partially resides in tools – taken to mean any artefact appropriated for use by humans – since they incorporate in their construction the results of past cognitive efforts. Hutchins' (1995) view of distributed cognition provides a means of investigating how individual teachers' knowledge is involved in a participatory relationship with technology. In this study, the terms readerly and writerly response (Bowe, Ball, & Gold, 1992, drawing on the work of Barthes) are introduced to indicate how and to what extent knowledge is distributed (Hutchins, 1995) across teacher and technology. A readerly response indicates an uncritical acceptance by the teacher of a (technological) tool for mathematics teaching. By contrast, a writerly response entails recognition that the design of such a tool is open to critique and potential modification. Departing from their original meaning, that writerly texts invite the reader to participate in meaning-making and are therefore in a sense superior to readerly texts that make no such demands, the use of these terms in this study takes a less normative view. Instead, a readerly/writerly response indicates the role of individual teachers' knowledge in interacting with technology to produce mathematical knowledge made available in the classroom – or more pertinently, in the case of this study, in the interview. A readerly response suggests that the mathematical knowledge made available through this interaction is more dependent, i.e. more distributed, upon the technology, whereas a writerly response indicates that it is less so.

For the purposes of this study, the Knowledge Quartet provides a means of focusing on and analysing individual teachers' own knowledge in relation to using technology to teach mathematics i.e. within the participatory relationship with technology. The Knowledge Quartet emerged from research aimed at developing an empirically-based conceptual framework to guide lesson review discussions between teacher-mentor and student-teacher in the practicum placement of the Postgraduate

Certificate in Education course in the UK (Rowland et al., 2005). The purpose of developing such a framework was to focus these discussions on the mathematical content of the lesson under review. The Knowledge Quartet was initially developed from 24 lesson observations of student teachers, training to teach at primary level. These observations generated 18 codes relating to the student teachers' classroom actions that appeared significant in the sense that they were informed by the trainee's mathematical knowledge for teaching. The codes were then grouped into four super-ordinate categories, named Foundation, Transformation, Connection and Contingency. The foundation category consists of propositional knowledge of mathematical concepts and the relationships between them and of significant research findings regarding the teaching and learning of mathematics (Rowland et al., 2005). The second category of transformation refers to knowledge-in-action, concerning the ways that teachers make what they know accessible to learners: this category focuses in particular on their choice and use of representations and examples (Rowland et al., 2005). Connection also refers to knowledge-in-action, regarding the manner in which the teacher makes connections between different concepts, representations and procedures; and decisions about sequencing e.g. of topics. Contingency concerns the teacher's ability to 'think on one's feet', to provide an appropriate response to unanticipated pupil contributions, and also notable 'in-flight' teacher insights (Thwaites, Jared, & Rowland, 2011). While there are clearly no pupils to provoke contingencies in an interview context, technology can be a source of disruption to teachers' mathematical knowledge (Laborde, 2001). Indeed, in this study, contingent moments did arise through teachers' use of the GeoGebra file, however these are not the focus of this paper. The Knowledge Quartet has subsequently been examined in classrooms at secondary level (Thwaites et al., 2011) and in classrooms outside the UK, specifically in Ireland and Cyprus (Turner & Rowland, 2011), resulting in the addition of new codes and alteration of some of the original codes. Although Rowland et al (2005, p. 260) make use of an acquisition metaphor, implying individualist assumptions about knowledge by describing their foundation category as being about "knowledge possessed", Turner and Rowland (2011, footnote on p. 200) suggest that "this 'fount' of knowledge can also be envisaged and accommodated within more distributed accounts of knowledge resources". Hence the framework may be compatible with an account of teachers' knowledge as distributed e.g. across (technological) tools.

## Methodology

Four teachers were selected from a group of English mathematics teachers who took part in a survey of secondary school mathematics teachers' use of ICT (n=183) and who further agreed to be contacted as case study teachers (Bretscher, 2011; 2014). The four case study teachers, Robert, Michael, Edward and Anne, were chosen along two dimensions of variation likely to be associated with mathematical knowledge for teaching using technology, based on their responses to survey items. Firstly, the case study teachers were chosen to be two of the most student-centred (Robert, Anne) and two of the most teacher-centred (Michael, Edward) in their approach to mathematics teaching in general (not limited to ICT use) of those who volunteered. Secondly, two teachers were chosen to be from schools with a high level of support for ICT (Robert, Michael) and two with a low level of ICT support (Anne, Michael). In addition, the four case study teachers had described themselves as being confident with ICT. As technology enthusiasts, the case study teachers were likely to display mathematical

knowledge for teaching using technology; the variation in case selection aimed to highlight such knowledge – making it more ‘visible’.

Semi-structured interviews based around a GeoGebra file on circle theorems provided a common situation across which the case study teachers’ use of technology for teaching mathematics could be contrasted. The case study teachers were prompted to show and discuss how they would use a diagram presented in the GeoGebra file (see Figure 1) to demonstrate the angle at the centre theorem to their pupils. Circle theorems were chosen since it is a topic, in the English mathematics curriculum, which is commonly identified with the use of dynamic geometry software (Ruthven et al., 2008). It was therefore reasonable to assume that the case study teachers would be familiar with technological resources similar to the diagrams presented in the GeoGebra file and might even have previously used such resources in their own teaching. Thus they would be likely to have some mathematical knowledge for teaching circle theorems using the GeoGebra file, even if they were unfamiliar with the particular software. In addition, the topic of circle theorems is at the apex of geometry in the compulsory English mathematics curriculum, since it is typically where proof is introduced. Hence it provided a potentially challenging context even for experienced teachers who were both mathematically and technologically confident.

The GeoGebra file comprised three diagrams, all initially arranged in an ‘arrowhead’ configuration, relating to the circle theorem stating that angle at the centre of the circle, subtended by an arc, is double the angle at the circumference subtended by the same arc. The GeoGebra file also incorporated some text, setting the task of manipulating the diagrams in the pedagogical context of planning how to introduce pupils to this circle theorem based on a demonstration using these diagrams. In this paper, the analysis presented below focuses on the teachers’ discussion of the first diagram (D1) only which was designed to be similar to resources found on a web-search. Thus the case study teachers were likely to have at least some familiarity with a dynamic diagram like D1 and possibly have even used something similar in their own lessons.

Figure 1 Diagram 1 (D1) in the GeoGebra interview file on circle theorems

Before opening the GeoGebra file on circle theorems, the case study teachers were asked to practise ‘thinking-aloud’ whilst manipulating a GeoGebra file contrasting two constructions of a square. The semi-structuring of the interview allowed the author some flexibility to respond to events during the interview, whilst maintaining an overall structure that would allow for and facilitate comparison. The GeoGebra interviews generally took place in a mathematics classroom at the case study teacher’s school that was not being used for teaching at that time. The author’s laptop with mouse attached was

arranged on a desk so that both the author and the case study teacher could comfortably see the screen and use the mouse to manipulate D1, enabling collaboration on the task. Both the visual and audio aspects of the GeoGebra interviews were recorded on the author's laptop.

## Results and analysis

### Adhering to the starting configuration

Robert was the only case study teacher to consider modifying the starting configuration of D1 to suit his own pedagogical requirements. He suggested he might alter D1 so that the initial numerical example displayed when opening the GeoGebra file would be an almost implausibly 'nice' pair of numbers, setting the angle at the circumference to 60 degrees and the angle at the centre to 120 degrees as an example.

Robert: I'd probably I'd have it so when it [D1] came up I'd probably have it set up with I guess fairly nice numbers [drags D1 so angle CBD=60; CAD= 120] that they should be able to spot quite easily and I'd probably ask them what the relationship is. And then before dragging this point I'd probably you know I'd probably have it set up so that maybe it looks a bit well this is a kind of this is a nice symmetrical, that's horizontal, they almost look vertical you know. And so I'd probably ask them well what happens if I move this over here? Is it going to get bigger? Is it going to get smaller?

Interviewer, I: Can you show me?

Robert: So I probably would be, if this was an interactive whiteboard I'd be hovering over this and not actually touching it and saying I'm going to drag this this way. What's going to happen? And I'd probably try to lead them into, I probably wouldn't give them the option of it staying the same. I'd probably ask them is it going to get bigger or going to get smaller? To I guess when they see that it does stay the same to provide a bit of conflict there. And then I'd drag it and we'd drag it all the way around here and show that it never changes. [Rob-GGb-int, 13.6.2012]

His intention was to set up a situation that appeared 'too good to be true' so that pupils would assume no relationship was likely to exist and would therefore sustain cognitive conflict when the angle at the circumference remained invariant under drag, hopefully making the result more memorable. The other three case study teachers uncritically accepted the starting configuration, questioning neither the numerical example nor the geometric configuration. For example, Edward explained how he would begin using the diagram, without making reference to the starting position:

Edward: What I'd start with is look, just move B between C and D but don't cross it and move D just so it doesn't go further round than CD being a diameter. [Ed-GGb- int, 20.6.2012]

The geometric nature of the starting configuration, in particular, is important since it provides an implicit pedagogic structuring. For example, opening the GeoGebra file so that D1 initially displays an 'arrowhead' configuration implies a choice and use of examples and a decision about sequencing that alternative configurations will occur as a consequence of the arrowhead configuration, potentially

reinforcing the impression of the arrowhead as the standard configuration of the angle at the centre theorem. An alternative would be to open the GeoGebra file so that D1 initially displays the convex quadrilateral configuration as a means of challenging this apparent orthodoxy. In addition, the starting configuration tends to impose decisions about sequencing, since some configurations are more difficult to obtain depending on whether they require dragging point B, C or D only or a combination of these points.

The case study teachers' adherence to or modification of the starting configuration appears to coincide with the meaning of the code *adherence to textbook*, in the Foundation category of the Knowledge Quartet, in the sense that it describes a situation involving mathematical knowledge for teaching where a teacher decides either to adhere to or to modify the pedagogic structuring of mathematics by a teaching resource. The teacher's decision, implicit or explicit, regarding the pedagogic structure of the teaching resource provides an indicator of foundational knowledge. An implicit (i.e. uncritical) adherence to the pedagogic structure of the teaching resource implies a negative reading of the code. Thus Anne, Edward and Michael's uncritical acceptance of the starting configuration suggests they lack foundational knowledge that the starting configuration of D1 might be (usefully or otherwise) critiqued in terms of the pedagogic structuring it provides. Hence they make a readerly response to D1 (Bowe et al., 1992). Nevertheless, a readerly response might apparently result in a positive choice and use of examples say, if the pedagogic structuring of the resource was sound. Thus, confusingly, a readerly response could also be interpreted as a positive example of the code adherence to textbook.

A writerly response (Bowe et al., 1992) to D1 would entail a recognition that the starting configuration of D1 might be critiqued in terms of the pedagogic structuring it provides, resulting in an explicit decision either to adhere to or to modify the pedagogic structuring of the teaching resource. This suggests a positive reading of the code *adherence to textbook*. Indeed, an explicit decision to adhere to the pedagogic structuring of the teaching resource would be a positive example of the code *adherence to textbook* if the pedagogic structuring of the resource were sound. On the other hand, such a decision could also be interpreted as a negative example of the code if the pedagogic structuring turned out to be flawed in some way. An explicit decision to modify the pedagogic structuring of the teaching resource which resulted in improvement, would again indicate a positive example of *adherence to textbook* – this latter is also dealt with by the new code *use of instructional materials* under the Transformation category introduced by Petrou and Goulding (2011). However, Robert's decision to modify the starting configuration could be interpreted as a deterioration in the pedagogic quality of the initial choice of example: it is geometrically too close to being symmetric and the numbers are exceptional. Thus Robert's modification could be interpreted both as a positive and negative instance of the code *adherence to textbook* under Foundation and a negative example of *use of instructional materials*. This analysis is rather cumbersome and symptomatic of the Knowledge Quartet's relative lack of focus on knowledge in relation to teaching resources in general.

Finally, there is a slight discordancy in using this code to describe the case study teachers' adherence to or modification of the starting configuration, since the code specifically refers to a textbook and not a digital resource such as the GeoGebra file on circle theorems. The specificity of the *adherence to textbook* code derives from the non-digital technology context in which it was grounded. The discordancy may be ameliorated by a minor alteration to the code, so that it refers to a more generic

teaching resource as in *use of instructional materials* (Transformation) or *responding to the (un)availability of tools and resources* (Contingency).

## Discussion

The analysis presented in the previous section shows that the Knowledge Quartet remained a useful tool for focusing analysis on mathematical knowledge despite the shift away from the classroom context in which the framework was originally developed and grounded. This finding is not entirely surprising since although the classroom is a particularly important context, it is not the only context in which teachers are likely to employ their mathematical knowledge for teaching.

In addition, the analysis of the GeoGebra interview data suggested some minor modifications to the Knowledge Quartet, in relation to technology context, that might prove useful when re-applied back to the original classroom setting or to other settings where teachers employ their mathematical knowledge for teaching. The cumbersome analysis of situations involving the code adherence to textbook is symptomatic of the Knowledge Quartet's lack of focus on knowledge in relation to (digital) technology. The difficulty with this code is that it categorises situations involving the application of foundational knowledge both in perceiving the technology as something requiring a pedagogic critique and in terms of the quality of the critique applied to the teaching resource. The former relates to the teachers' foundational knowledge in adopting a readerly or writerly approach to the resource (Bowe et al., 1992). The latter is also dealt with under the Transformation category, specifically the code use of instructional materials, which additionally reflects back onto the teachers' foundational knowledge indicated by the quality of the pedagogic critique applied to transform the resource for the purpose of teaching. There is no easy way to ameliorate this difficulty within the Knowledge Quartet, however, adherence to textbook could be modified to reflect a broader range of teaching resources rather than privileging this paper-based technology. Furthermore, as a result of new codes added by a range of researchers, the codes of the Knowledge Quartet use an impromptu variety of terms to refer to teaching resources including textbook, instructional materials, tools and resources. The variety of terms is not intended to make any productive distinctions, as far as I am aware, thus it might simplify and improve the coherence of the Knowledge Quartet to settle on a particular term or group of terms to refer to teaching technologies. Finally, the analysis above provides an exemplification of the Knowledge Quartet in relation to digital technologies, albeit not in a classroom context. This exemplification might be useful in helping teachers to use the Knowledge Quartet as a tool for professional development in relation to their use of technology, as described in Turner and Rowland (2011).

# An analysis of the nature of the knowledge disseminated by a mathematics teacher training policy: The PROFMAT case

Marlova Estela Caldato<sup>1</sup> and Miguel Ribeiro<sup>2</sup>

<sup>1</sup> Federal Technological University of Paraná – UTFPR, Brazil; [maracaldatto@yahoo.com](mailto:maracaldatto@yahoo.com)

<sup>2</sup> State University of Campinas – UNICAMP, Brazil; [cmribas78@gmail.com](mailto:cmribas78@gmail.com)

*This paper discusses the nature of the knowledge disseminated by the Brazilian public policy PROFMAT for training teachers on natural numbers, based on the analysis of one of the textbooks that outline the formative activities developed in this program. This discussion was structured and developed from a conceptual and analytical model of the mathematical knowledge of teachers-Mathematics Teacher's Specialized Knowledge (MTSK). The analyses and discussions developed suggest that this public policy favors only part of the knowledge taken by the literature as essential for the practice of the mathematics teacher in the school.*

*Keywords: Mathematics teacher's specialized knowledge, PROFMAT, public policy.*

## Introduction

Educational policies are configured as sources pertinent to the investigative processes that seek to identify the specificities of the teacher's knowledge (Stylianides & Ball, 2004), since they demonstrate the response produced by the government bodies to an issue that permeates the educational discussions related with what teachers need to know in order to teach mathematics adequately (Ball, Lubienski, & Mewborn, 2001).

Thus, the object of discussion of this article is a Master's Program in Mathematics (PROFMAT), aimed at the continuous training of mathematics teachers (lower and upper secondary), developed in all Brazilian states and financed by the country's government – assuming the character of Public Policy. According to the official documents, such a Program aims to provide in-depth and relevant mathematical training for teaching in Basic Education, seeking to give teachers a certified qualification for the mathematics teacher profession (Bsm, 2017).

The role played by the mathematical knowledge of teachers to improve the quality of learning opportunities justifies, at least in part, the growing focus of research on teachers' mathematical knowledge (Stylianides & Stylianides, 2014). This knowledge has been widely studied and, from different points of view, diverse conceptualizations of teacher knowledge have emerged (e.g., Knowledge Quartet - Rowland & Turner, 2007, MKT - Ball, Thames & Phelps, 2008; COACTIV – Kleickmann et al., 2015; MfT-Stylianides & Stylianides, 2014; MTSK-Carrillo et al., 2018). In this text, we focus on the Mathematics Teacher's Specialized Knowledge - MTSK conceptualization (Carrillo et al., 2018) as the analytical model of this type of knowledge. Thus, we will support the MTSK to discuss teacher training developed within the scope of PROFMAT, seeking to answer the following question: what knowledge about Natural Numbers and their teaching are presented (and not presented) in the textbook that guides a part of the training developed in PROFMAT?

## Theoretical framework

The MTSK is an analytical model that assumes that the professional practice of the math teacher requires a set of specific knowledge strictly related to the teaching of mathematics. This includes the meanings, properties and definitions of particular topics, means that favor the construction of the understanding of the subject, connections between mathematical items, knowledge of mathematics teaching and characteristics associated with learning mathematics, among others (Carrillo et al., 2018). In this sense, the MTSK model (Figure 1) considers three subdomains in Mathematical Knowledge (MK) and three in Pedagogical Content Knowledge (PCK). In this way, MK is subdivided into: Knowledge of Topics (KoT), Knowledge of the Structure of Mathematics (KSM) and Knowledge of the Practice of Mathematics (KPM), while PCK is subdivided into: Knowledge of Mathematics Teaching (KMT), Knowledge of Features of Learning Mathematics (KFLM) and Knowledge of Mathematics Learning Standards (KMLS).

**Figure 1: Sub-domains of the MTSK**  
(Carrillo et al., 2018)

The KoT includes phenomenological aspects, meanings of specific concepts and examples that characterize specific aspects of the topic addressed, aside from contemplating the disciplinary content of the mathematics addressed by textbooks and other materials of a pedagogical nature. KSM refers to the understanding that the knowledge of teachers, besides including concepts as isolated elements, must integrate them into a system of connections, which allows the teacher to understand certain advanced concepts from an elementary perspective and develop certain concepts from an advanced perspective.

KPM covers aspects related to mathematical thinking, such as knowledge of the different ways of defining, arguing or proving in mathematics, as well as knowledge of mathematical syntax. The teaching action involves the knowledge of how this teaching can and should be developed, so the KMT contemplates knowledge as knowing different teaching strategies that allow the teacher to foster the development of procedural and conceptual mathematical capacities. In the same way, this

subdomain predicts that the teacher needs to know examples that awaken the intuition in the student about some concepts, as well as resources that allow the teacher to induce his students to learn, through manipulation, certain mathematical concepts. Knowing how students learn mathematical content is knowledge that every teacher should possess. Thus, KFLM encompasses the knowledge of the characteristics of the process of understanding the different contents by the students, the errors, difficulties and obstacles associated with each concept and the language used by students in relation to the concept worked in the classroom. The KMLS refers especially to the teacher's knowledge of the curriculum adopted by the institution in all stages / levels of education. This knowledge can be complemented with information present in the productions originating from research in the area of mathematics education, with information provided by experienced teachers about the expected learning in each stage (For further deepening and detailing the subdomains see Carrillo *et al.* 2013, Flores-Medrano *et al.*, 2016 , Carrillo *et al.* 2017).

### **The context of the study: The PROFMAT**

PROFMAT is a teacher training program promoted by the Brazilian Federal Government and developed in partnership with 96 higher education institutions (universities and colleges) that train teachers of mathematics (lower and upper secondary), organized in the format of professional **masters**. This program has a length of 2 years and is basically composed of a list of 9 subjects, each with a 120-hour workload. Of these, 7 of them are considered as mandatory and titled "Real Numbers and Functions", "Discrete Mathematics", "Arithmetic", "Geometry", "Problem Solving", "Calculus Fundamentals" and "Analytical Geometry". The "elective" disciplines can be chosen by students from the following list: Topics of Mathematics History; Topics of Number Theory; Introduction to Linear Algebra; Differential and Integral Calculus Topics; Mathematics and Actuality I; Mathematical Modeling; Algebraic Polynomials and Equations; Spatial Geometry; Topics of Mathematics; Probability and Statistics; Educational Evaluation; Numerical Calculation; Mathematics and Actuality II. The final course work refers to the production, by the academic under the guidance of a university professor, of a product/work that can be presented in different formats (dissertation, literature review, article, patent, applications, teaching and instructional materials , media programs) and that addresses topics relevant to the Mathematics curriculum of Basic Education and promotes the impact on didactic practices in the classroom.

These disciplines are based on the collection of textbooks entitled "PROFMAT Collection", whose elaboration is the responsibility of mathematicians, and each discipline is based on a textbook from the collection, which is adopted by all 96 institutions where PROFMAT is developed.

Here we focus on analyzing and discussing one of the elements that make up the teacher training process developed in the scope of PROFMAT from the analytical model MTSK. However, the analyzes presented here are part of a project that has analyzed a multiplicity of elements of the PROFMAT: policy texts, textbooks that guide the training activities; class episodes; and PROFMAT academic productions (answers to questionnaires, works, etc.).

In this analysis, we classify all the contents that compose the textbooks (definitions, axioms, theorems and demonstrations, properties, activities, exercises, explanations, etc.), from the subdomains of the MTSK framework, with the objective of identifying the presence and absence of knowledge related

to the teacher's practice in mathematics teaching, as proposed by Carrillo and contributors (Carrillo *et al.*, 2013, Flores-Medrano *et al.*, 2016, Carrillo *et al.*, 2017, Carrillo *et al.*, 2018).

It is highlighted in this scenario that, through the following discussion presented, we will seek to note indications of the nature of the knowledge disseminated by PROFMAT, since the knowledge produced from a textbook depends on the manipulation that is made of this didactic material, particularly, the manipulation developed by the teacher who uses it.

Due to limitations of space, we focus here on two chapters of one of the textbooks used in PROFMAT called "real numbers and functions" (which describes the work developed in the mandatory subject that has the same name). We chose to analyze this textbook because it guides the teaching activities of one of the four compulsory subjects developed during the course of the PROFMAT, besides addressing mathematical themes that permeate themes also common to the school curriculum, such as numerical sets and functions (NCTM, 2000). In this analysis, we will focus on "Natural Numbers" and for the analysis, we use MTSK as a theoretical lens as a way of discussing the nature and focus of such a course. With this, in the sequence, we will present some representative examples of the analyzes that we developed.

## **Analysis and discussion**

The textbook "Real Numbers and Functions" (Lima, 2013) is structured from the following sequence of themes (chapters): Sets; Natural Numbers; Cardinal Numbers; Real Numbers; Related Functions; Quadratic Functions; Polynomial Functions; Exponential and Logarithmic Functions; Trigonometric Functions. This organization is justified by the author, who states "Mathematics deals primarily with numbers and space. Therefore, the sets most frequently found in Mathematics are numerical sets, geometric figures (which are sets of points) and the sets that derive from them, such as the function sets, those of matrices" (Lima, 2013, pp. 02). This structure presents opportunities for the development of MK, in particular KSM, by teachers in training, since it favors the (potential) development of connections between the numerical sets and functions that establish relations between subsets of  $\mathbb{R}$ .

The chapter "Natural Numbers" is initiated by the author with a description of the meaning of the term "numbers" as being "abstract entities, developed by man as models that allow to count and measure, therefore to evaluate the different quantities of a magnitude" (Lima, 2013, pp. 22). "Mathematical definition" is described as "a convention consisting of using a name, or a brief sentence, to designate an object or property, the description of which would normally require the use of a longer sentence" (Lima, 2013, pp. 23), axiom and primitive concept. These descriptions can be associated with MTSK by means of KPM, as it returns to the fundamentals associated with mathematical proceedings.

The author also presents a description of the axiomatic method and in relating it to the school argues that "[...] it is not appropriate to present Mathematics in an axiomatic form. But it is necessary for the teacher to know it can be organized in the manner outlined above" (Lima, 2013, pp. 23). As this fragment shows, the author argues that it is necessary for the teacher to know that mathematics can be organized in the axiomatic form (KPM), but it does not elucidate, for example, why it is necessary

for the teacher to know this form of mathematical exposition (KoT), nor "how" (KMT) and "when" (KMLS) this method would aid in the teaching of mathematics.

Lima (2013, pp. 26) links natural numbers to historical aspects (potential indications of KPM) by saying that "Slowly, to the measure that it has become civilized, mankind has taken over this abstract model of counting (one, two, three, four, ...) which are the natural numbers". The author also argues that, currently, the set of natural numbers can be described as "concise" and "precise" by Peano's theory, which states that " $N$  is a set, whose elements are called natural numbers. The essence of the characterization of  $N$  lies in the word "successor" (if  $n, n' \in N$ , then  $n'$  is the successor of  $n$  means that  $n'$  comes soon after  $n$ , there being no other natural numbers between  $n$  and  $n'$ ), which is considered a primitive concept because it is not explicitly defined. The author then mentions that "everything" about natural numbers "can be demonstrated" from Peano Axioms<sup>1</sup>.

According to Lima (2013, pp. 27), "an ingenious process, called a decimal number system, allows us to represent all natural numbers with the help of the symbols 0, 1, 2, 3, 4, 5, 6, 7, 8 and 9. In addition, the first natural numbers have names: the successor of number one is called two, the successor of two is called three, etc." This presentation of decimal numbering systems can be linked to KoT (knowing the set) on the one hand, and on the other, to KPM (knowing the role of the successor and the associated mathematical structure – e.g., continuity, density). Meanwhile, the author avoided discussing, for example, the different aspects of the mathematical knowledge underlying the construction and use of the decimal system (KoT), such as the notion of grouping, the language involved in the reading of numbers and the idea of positional value (KoT; KPM). In this case, it is important to highlight the lost opportunity for elaborating some discussions on, for example, the resources and examples in and for teaching such topic (KMT), concerning the students' difficulties (KMLM) and the content of the official documents (KMLS).

Lima (2013, pp. 27) then argues that the set  $N = \{1, 2, 3, \dots\}$  is a "sequence of abstract objects that are, in principle, empty of meaning" and that "each of these objects has only one place determined in this sequence". Since "Every number has a (single) successor and, with the exception of 1, it also has a single predecessor. Viewed in this way, we can say that natural numbers are ordinal numbers: 1 is the first, 2 is the second, etc.". In this fragment, Lima presents a powerful scenario for an exploratory work of KoT (when discussing the definition of natural numbers); however, although the author recognizes that the objects of the sequence of natural numbers are abstract and are in principle empty of meaning, he does not discuss, for example, what the teacher's work could be in addressing this content in the school environment (PCK), in addition to the symbol of "..." being placed in the representation of the set of natural numbers, but without making any comment about the meaning of this symbol (KoT and KPM). Lima also does not present indicatives of "how" (KMT) and "when" (KMLS) Peano axioms could be addressed in math classes at school.

---

<sup>1</sup> I) Every natural number has a single successor; II) Different natural numbers have different successors; III) There is a single natural number, called one and represented by the symbol 1, which is not a successor to any other; IV)  $X$  is a set of natural numbers (that is,  $X \subset N$ ). If  $1 \in X$  and if, in addition, the successor of every element of  $X$  still belongs to  $X$ , then  $X = N$ .

The author also defines the "fundamental" operations among natural numbers, and the addition of numbers  $n, p \in \mathbb{N}$  corresponds with the sum " $n + p$ " and multiplication associates the product " $np$ " (Lima, 2013). It also re-elaborates them in such a way as to present the sum " $n + p$ " as "the natural number that is obtained from applying  $n$   $p$  times following the operation of taking the successor", so that " $n + 1$  is the successor of  $n$ ,  $n + 2$  is the successor of the successor of  $n$ , etc." (Lima, 2013, pp. 29) and presents, as an example, the addition of  $2 + 2 = 4$ , where " $4$  is the successor of the successor of  $2$ ". For the product and defined as  $n.1 = n$  and, when  $p \neq 1$ , " $np$  is the sum of  $p$  plots equal to  $n$ ". In this context, it is argued that "until we know how to use natural numbers to make counts, there is no point in speaking in ' $p$  times' and ' $p$  plots'. Therefore, fundamental operations must be defined by induction" (Lima, 2013, pp. 29). In the following, Lima defines Addition and Multiplication by induction (KPM - from a level of knowing how to perform). However, the operations are not linked to the practices of mathematics teachers, which could have been done by discussing how these operations are approached in the school curriculum (KMLS), what kind of resources - and their intentionality - could be used to explore such operations with students (KMT) in order to understand what they do and why; and the students learning processes linked to understanding multiplication mainly as a solely repeated additions (KFLM).

In addition, the author constructs the set of natural numbers and only two of their operations (addition and multiplication), omitting the definition of the operations of subtraction and division between natural numbers (KoT), which are also used by teachers in school. The author also does not link the definitions of addition and multiplication (and consequently of subtraction and division) to the algorithms commonly used by school materials (KMLS) and used in calculating these operations (KoT). Another relevant observation refers to the non-linking of this work with one of the main practices of the Mathematics teacher, to give meaning to the operations among the natural ones through problem situations and problem history (KMT).

In addressing the Natural Numbers, Lima (2013) presents the order relationship between natural numbers in terms of addition ("Given  $m, n \in \mathbb{N}$ , it is said that  $m$  is less than  $n$ , and we write  $m < n$  to mean that there is some  $p \in \mathbb{N}$  in which  $n = m + p$  ") and presents the properties of Transitivity, Trichotomy, Monotonicity of Addition and Multiplication, and Good Ordination. This fragment highlights the potential of the work in the development of KoT and KPM. However, the author does not present any indication of discussions regarding PCK subdomains.

In the thread of the work the author presents and demonstrates properties of  $\mathbb{N}$ : Associative property of Addition, Commutative property of Addition, Distributive property, Commutative property of Multiplication, Cancellation Law for Addition, Transitive Order Relationship, Trichotomy, Monotonicity, Cancellation Law for Inequalities and the Principle of Good Ordination. Lima argues that the adoption of this approach was because it expresses "[...] some basic facts about natural numbers, which are used very often, most of the time without us stopping to ask how to prove them." He argues further that the "[...] objective is to show how such facts result from Peano axioms. There is no creative reasoning or elaborate methods to prove them. In all demonstrations, the central role is played by the Induction Axiom" (Lima, 2013, pp. 31).

This approach of N properties again highlights the potential of the material in relation to the development of KoT and KPM. However, at no point in the work does the author present any discussion that may be associated with the development of PCK. For example the author does not discuss, whether these demonstrations are accessible to students of basic education, whether they need to be adapted (KMT) to become accessible to school students (KFLM) and in which years it is possible to use them (KMLS).

## Final comments

The developed analyses of a textbook that guides the formative practice in a discipline of PROFMAT show indications of the nature of the knowledge disseminated through this public policy of continuous training of teachers that aims to impact the quality of the learning of Brazilian students. Thus, based on the MTSK, it was found that elements of MK are considerably favored, particularly those associated with properties and definitions (KoT) and mathematical practice (KPM), such as the forms of validation and demonstration and the use of formal language. On the other hand, this material presents very few indications of the presence of knowledge related to the PCK, such as those related to the characteristics of the teaching (KMT) and learning (KFLM) of Natural Numbers and how this content is included in the school curriculum (KMLS).

The results presented provide us with indications that this public policy favors only part of the knowledge taken by the literature (Carrillo *et al.*, 2013; Flores-Medrano *et al.*, 2016; Carrillo *et al.*, 2017; Scheiner *et al.*, 2017; Carrillo *et al.*, 2018) as essential for the practice of the mathematics teacher in school. With this, it is possible to affirm that PROFMAT will not be able to fully achieve the objectives it proposes, which is to change the mathematical education of the country qualitatively and quantitatively, especially if we consider that the work developed in this program follows rigid evaluation standards that are guided by the textbooks (see Caldatto, 2015, Caldatto, Pavanello & Fiorentini, 2016).

# Prospective primary teachers' knowledge about the mathematical practice of defining

Myriam Codes<sup>1</sup>, Nuria Climent<sup>1</sup> and Isabel Oliveros<sup>1</sup>

<sup>1</sup> University of Huelva, Huelva, Spain

[myriam.codes@ddi.uhu.es](mailto:myriam.codes@ddi.uhu.es), [climent@uhu.es](mailto:climent@uhu.es), [isabeloliverosescobar@gmail.com](mailto:isabeloliverosescobar@gmail.com)

*This study concerns the knowledge of two prospective primary teachers about the mathematical practice of defining. Starting with their analysis of a video recording of a primary lesson on constructing a definition of a polygon, the trainees discussed what it means to define in mathematics. Through analysis of the content of this discussion, we identified what they considered to be the nature of this practice and the features they felt a good definition should embody. The findings demonstrate that students tend to consider demonstrations as the touchstone of mathematical practice, and that they do not consider the use of examples as a valid element of formal mathematics. At the same time, they recognize that definitions must meet the criteria of hierarchy and minimality but see no need for the criteria of existence and arbitrariness.*

*Keywords: Teachers' knowledge, mathematical practice, defining, student teacher.*

## Introduction

Defining is a common practice in mathematics classes at all levels but is something not always dealt with in all its facets: establishing the necessary and sufficient conditions of a concept, preferably the minimum necessary, using only previously defined concepts without utilising the word assigned to the concept in the definition itself (Zazkis & Leikin, 2008).

What is more, definitions can be arbitrary, in the sense that concepts can be defined in different ways according to the particular aspect one wishes to foreground. This arbitrariness can disconcert students (Vinner, 1991), and it is the teacher's job to manage such uncomfortable facts of mathematical life and decide when his or her students are ready to meet them.

Involving students in the process of defining promotes the construction of knowledge (Edwards & Ward, 2008; Leikin, Berman & Zaslavsky, 1998; Villiers, 1988). Regardless of whether the teacher decides to tackle certain aspects of defining (such as their arbitrariness) with their students at a particular moment, if he or she wants them to generate definitions for themselves rather than memorise given definitions, they will necessarily have to learn how to define in mathematics. Hence, achieving a certain depth of understanding regarding the meaning of the practice of defining, the characteristics of a good definition and the role it plays in mathematics learning enables the teacher to base their classroom practice on sound foundations. In this respect, Zazkis and Leikin (2008) regard teachers' conceptions of the notion of defining as a fundamental requirement for successful teaching.

In this paper, we describe two prospective primary teachers' knowledge about the notion of defining in mathematics, based on their discussion of a video. This understanding forms a part of their knowledge of practices in mathematics, as we explain in the theoretical framework below.

## Theoretical framework

Defining, like demonstrating or arguing, is one of the basic elements of the work of mathematics. We can say, then, that these elements form a part of mathematics practice, in the sense that they allow us to do mathematics. Knowledge of practices in mathematics supposes knowledge of the syntax of mathematics consistent with Schwab (1978). A teacher's knowledge of practices in mathematics (henceforth KPM), together with their knowledge of topics and the structure of mathematics constitute the mathematical knowledge which in the *Mathematics Teacher's Specialised Knowledge* model (MTSK) is considered necessary for teaching the subject (Carrillo-Yañez et al., 2018). In addition to mathematical knowledge, the model takes account of the domains of pedagogical content knowledge and beliefs about mathematics and mathematics teaching and learning. However, in this study, we deal with neither prospective teachers' beliefs nor pedagogical content knowledge.

Understanding the notion of defining involves recognition of the role that definitions play in mathematics and the characteristics they embody, or at least it is desirable for them to embody (Zaslavsky & Shir, 2005). Zaslavsky & Shir (2005) suggest the following features as characteristic of a good definition:

... a mathematical definition must be *noncontradicting* (i.e., all conditions of a definition should coexist) and *unambiguous* (i.e., its meaning should be uniquely interpreted). In addition, there are some features of a mathematical definition that are imperative only when applicable: A mathematical definition must be *invariant* under change of representation; and it should also be *hierarchical*, that is, it should be based on basic or previously defined concepts, in a *noncircular* manner. (Zaslavsky & Shir 2005, p. 319)

Van Dormolen and Zaslavsky (2003) offer logically necessary criteria for a good definition, among others, the criterion of hierarchy (it should be described as a special case of a previously determined more general concept). In contrast to Zaslavsky and Shir (2005), the former regard hierarchy as a necessary characteristic. In addition to this feature, they include the criteria of existence (there must be proof of the existence of at least one instance of the new concept), equivalence (where more than one definition exists, they must be demonstrated to be equivalent), and axiomatization (it should fit into a deductive system such that when one reaches the point where the criterion of hierarchy can no longer be applied, we can resort to axioms or postulates).

There are other features for which there is a lack of agreement as to whether they are necessary or not. Foremost among these is the criterion of minimality.

A definition is considered minimal if it is economical, with no superfluous unnecessary conditions or information. That is, a minimal definition should consist only of information that is strictly necessary for identifying the defined concept. (Zaslavsky & Shir, 2005, p. 320)

A study by Leikin and Winicki-Landman (2000) involving secondary teachers highlights the rigour of a definition, although from a pedagogic point of view, other features are underlined, such as the definition being intuitive, being written clearly enough for the students to grasp with ease, combining what they already know with what they need to know, being appropriate for solving problems and

enabling generalisations to be made. Relaxing the rigour with which one applies the criterion of minimality tends to be motivated by pedagogical considerations.

There have been various studies into teachers' and prospective teachers' notions of what constitutes a mathematical definition. These have found, among other things, that prospective teachers do not always know the difference between a theorem and a definition (Leikin & Zazkis, 2010) and are sometimes unaware of the arbitrariness of definitions in geometry (Linchevsky, Vinner & Karsenty, 1992).

Escudero, Gavilán and Sánchez-Matamoros (2014), in their study about prospective primary teachers, describes various ways in which they understand what a mathematical definition is and tracks the changes in this understanding. From this progression, from naming to giving a list, from naming to giving a list of minimal features, and from giving a list of features to equivalent definitions, the authors infer the assimilation of some of the criteria of mathematical definitions discussed above. In particular, the recognition of minimality and equivalence is indicative of a more advanced understanding of what constitutes a mathematical definition. Elsewhere, Sánchez and García (2014), again with prospective primary teachers, find potential points of conflict between criteria associated with mathematical definitions (understood within the study as mathematical norms) and sociomathematical norms. For example, minimality comes into conflict with the sociomathematical norm which requires students to explain themselves as fully as possible in response to a classroom task, or that they should make use of all the data and properties in a figure. Conflicting requirements such as these could account for the difficulty which students experience with some of the mathematical attributes.

## **Data collection and analysis**

In Spain, the initial education for teachers on Primary Education corresponds to a four-year degree. Then they can obtain a general teaching graduate or specific on sports, music, foreign language or special education. At the University of Huelva, for each year, a compulsory Mathematic subject is planned. These subjects deal with content knowledge and pedagogical content knowledge about problem solving (first year), numbers and arithmetics (second year), statistics and measurements (third year) or geometry (fourth year). In these subjects, some concepts are reviewed in depth with regards to the Knowledge of Practices in Mathematics, like heuristics to solve Mathematical problems, proofs, types of proofs, and language and notation role.

This study takes the form of a one-on-one teaching experiment (Cobb & Gravemeijer, 2008) in which three prospective primary teachers trialled activities ultimately intended for use with a group of primary trainees on the subject Mathematics Education: Geometry. The participants' selection was intentional because of their particular disposition towards reflection on mathematics teaching and learning, and their sound knowledge of mathematics. We make use of only two participants' data in this paper; they will be called Ismael and Ramón. At the time of the study, they both were in the third year of their degree, so they have not taken the subject on Geometry. The purpose behind the choice of these particular students was to measure the development potential of the activities in a favourable environment.

Here we focus on the first part of the teaching experiment, in which the prospective teachers individually watched and analysed a video recording of an actual primary lesson. After writing their individual impressions, which they handed in to the teacher educators, the group came together to discuss the lesson, with one of the educators/researchers in the role of moderator.

The video analysed by the trainees featured a year 5 primary group (11 years old), in which their teacher introduced the topic of defining polygons by showing the pupils a bag with polygons and non-polygons shaped cards. The lesson was conducted as a whole-class activity, with pupils going up to the board one by one to take a figure from the bag and place it in one of two groups (they could create two groups, without being given any previous criteria). The teacher expected the pupils to apply the criteria “is a polygon”. The classification task formed the basis of the follow-up activity in which the class constructed a definition of polygon together. This video has been chosen as it exhibits the mathematical practice of defining and it allows us to show teacher’s knowledge about this practice. One of the objectives of this activity (the analysis of the Primary education class), is that future teachers must do a reflection about what is a definition within a mathematical context and which characteristics a mathematical definition could have.

The research question we are intending to respond to, is which knowledge about the mathematical practice of defining both prospective primary teachers (henceforth PPTs) show.

Data to solve the research question come from the individual analysis document of the PPTs and the transcription of the oral discussion (audio recorded). The units we will show belong to the discussion transcription. In this discussion and also for everything concerning to knowledge about the practice of defining, the main objective of the researcher and moderator is, for the first instance, to make the PPTs to glimpse their ideas. During the individual PPTs analysis, some comments came up concerning to characteristics of the definition built in the Primary lesson (e.g. “they have repeated elements”). The most frequent questions to the PPTs (during the discussion of their individual analysis) focused on their interpretation of the definition practice. Consequently, the responses showed which characteristics the PPTs linked to a mathematical definition.

The group discussion of the video was itself audio-recorded and subsequently transcribed. Below we analyse the transcript in terms of the elements discussed in the theoretical framework, essentially the features of a good mathematical definition. Therefore, we made a content analysis in which we selected those fragments in which PPTs considered the mathematical practice of defining developed in the Primary lesson and they related the features associated to a mathematics definition. We connected these fragments to the characteristics of a mathematics definition from the theoretical framework. This analysis is first undertaken by each researcher individually and afterwards jointly agreed. This process let us build our common explanation from our observation.

### **Knowledge of the mathematical practice of defining**

One of the aspects which two of the prospective teachers focus on in their analysis is mathematical definitions, and in particular the role of examples in constructing a definition:

Educator:      What do you think is the aim of the first task?

- Ismael: ...what he's looking for is the definition, what's happening is that he's starting from examples so that they see the differences between what it [a polygon] is and what it isn't.
- Educator: What do you think about the fact that he starts from examples to get there, to get them to construct the definition of a polygon?
- Ismael: As an item of mathematics, it is not mathematically correct to construct a definition from examples. [...] Maybe it's good in terms of getting the pupils to understand, but not in terms of mathematics.
- Ramón: Is it more correct or less correct in mathematical terms? Yeah, starting from examples could be less correct, but for primary children it's an introduction. And besides, in our lessons when we do demonstrations what do we do first? Try a few numbers to see and then afterwards do the demonstration well.

Ismael appeals to the argument of *rigour* which features in the literature in contradistinction to pedagogical considerations (Leikin & Winicki-Landman, 2000; Zazkis & Leikin, 2008). In his view, the use of examples does not meet the standards of rigour demanded by mathematics, but justifies their use for the pedagogical advantage they afford in making a mathematical concept accessible to the primary pupils. Ramón concurs, criticising the use of examples to construct a definition. Both prospective teachers settle on demonstrations as a prototypical practice of formal mathematics, and, aware that in formal mathematics it is not considered valid to perform a demonstration via examples, they extrapolate the proscription to definitions. The use of examples is not intrinsic to formal mathematics. It can serve to make a mathematical object accessible, such as the rubric in demonstrations, but it is not a rigorous procedure.

Both the prospective primary teachers (henceforth PPTs) seem to dispense with the *criterion of existence* for definitions, whereby examples serve as proof of the existence of at least one mathematical object fulfilling the definition.

However, at another point in the debate, Ramón appraise the use of examples to define a mathematical concept, in reference to the examples given by the cardboard cut-out figures:

- Ramón: If the pupils are given a figure with edges, how are they going to know what is inside and what is outside?

The PPTs insist that a new mathematical concept should be generated on the basis of differentiating the properties of pre-existing concepts (*the criterion of hierarchy*), while also making a contrast with properties the concepts do not have. In other words, it is not sufficient to present images (examples) which illustrate the properties of a concept, rather it is necessary to include images which illustrate these very properties by their absence. In this way, a deeper understanding is achieved of the concept being defined. This appraisal might also be associated by the PPTs with the pedagogical advantages it affords more than with mathematical practice itself.

The *criterion of arbitrariness* does not seem to be considered by the prospective teachers, who, it would seem, believe that mathematical concepts can have only one formal definition. Accordingly,

in the following turn, Ramón gets impressed by how the definition built in the primary school classroom is so exact (to which he believes is the unique right definition):

Ramón: [...] the idea of the activity is that they do the classifying, as if polygons had never been classified before and they were doing it for the first time, so that they realise that the classification system they come up with is similar to the actual one. [...] It surprised me how well they managed it, coming up with a definition from examples, that primary children can make such identical definition simply from examples.

On the other hand, the prospective teachers do recognize the *criterion of minimality* as a desirable attribute of a mathematical definition, when they come to consider the wording of the definition the class finally agree on (a polygon is *a flat shape, it has angles, it has vertices, it has straight sides and no curves; all the sides are joined at the end*):

Ramón: It made me laugh when they put in the definition “it has straight sides and no curves,” it’s the same thing.

Educator: Would you have cut that out?

Ramón: At the end of the recording, one pupil says that not having any curved lines is the same as having all the sides straight, and it wasn’t necessary to say both things.

Ismael: I think that if that’s the first time they’ve done this and the children have reached that conclusion, then it’s fine, even if it’s redundant. I’d leave it like that, and then next time we did the topic I’d suggest we cut out that bit. You work on it a bit so it looks a bit more like the definition we have.

## Discussion and conclusions

The prospective teachers involved in this study seem to identify formal mathematics practices with the practice of demonstrating. Their touchstone in this regard is mathematical rigour, which exerts its influence over the practice of defining. In particular, the use of examples falls short of the demands of rigour, and can be justified only on pedagogical grounds or as a means of making a mathematical object more accessible before defining it formally. They recognise that a mathematical definition should meet the criteria of hierarchy and minimality, whilst they do not see the need for the criteria of existence or arbitrariness. This lack of recognition of the criterion of arbitrariness mirrors the results of other studies (Linchevsky, Vinner & Karsenty, 1992). The prospective teachers also tend to regard the practice of defining as supplying a list of minimal features, a result consistent with the findings in Escudero, Gavilán and Sánchez-Matamoros (2014).

In the course of the PPTs’ debate about the essential features of a good definition, they frequently consider pedagogical criteria over mathematical considerations about a good definition. This posture is consistent with the professional profile of primary teacher and coincides with practices observed at other levels of education (Leikin & Winicki-Landman, 2000; Zazkis & Leikin, 2008).

These findings are particularly relevant to the context of developing teaching strategies for training prospective teachers in terms of their knowledge of practices in mathematics, specifically in this instance the nature of definitions. In particular, with respect to the initial training provided for

prospective primary teachers at the university in which the study was carried out, there is cause for rethinking the role given to demonstrations, as their pre-eminence on the syllabus vis-à-vis other practices seems to be leading students to regard it as the touchstone of mathematical practices.

At the same time, before their initial training, the prospective teachers have little knowledge of formal mathematics as the mathematical knowledge they know is with regards to scholar mathematics. Taking the opportunity presented by their training to approach the nature of different mathematical practices should enable them to develop a more advanced view of what constitutes mathematics, building a bridge between school and advanced mathematics (issue that is also addressed in Crisan, 2019, February). The transition, however, from knowledge based on intuitions to that based on formal definitions and their features is not without its challenges (Bampili, Zachariades & Sakonidis, 2017).

In this paper, we have focused our analysis on the knowledge of two prospective primary teachers about the mathematical practice of defining, although data also reveal their conceptions about mathematics and about teaching and learning. The video recording was used as a starting point to reflect on the mathematical practice of defining and to validate this practice inside school mathematics. It might be considered the relationship between the selected video and the knowledge that prospective primary teachers have shown, for example, the fact that the polygon definition was built from polygon and non-polygon examples in the context of a primary school classroom. For future work, we will investigate on these issues. Also, we will consider extending this study to prospective kindergarten teacher and secondary teacher, in order to design task to strengthen their knowledge about the mathematical practice of defining.

# Empowering teachers conceptually and pedagogically through supporting them in seeing connections between school mathematics and relevant advanced mathematics knowledge

Cosette Crisan

UCL Institute of Education, University College London, UK; [c.crisan@ucl.ac.uk](mailto:c.crisan@ucl.ac.uk)

*Since ‘advanced mathematics knowledge’ (AMK) was first conceptualized by Zaskis and Leikin (2009), researchers have striven to determine whether teachers’ ability to identify explicit connections between AMK and the mathematics taught in school is a rare gift of only a few teachers or whether specific prompting is needed to develop this ability in teachers. In this paper we provide empirical evidence showing that those teachers who attended a CPD designed to support them to ‘see’ and make explicit such connections, have increased their awareness of the implications for the teaching and learning of school mathematics topics in ways that allow for creating a solid foundation for development of further, more advanced ideas in the school mathematics curriculum. We thus propose that any mathematics teacher, irrespective of their academic background, could benefit from professional development opportunities where explicit guidance is provided in terms of the relevant AMK and how it informs school mathematics teaching and learning.*

*Keywords: Advanced mathematics knowledge, mathematics knowledge for teaching, specialized knowledge, continuous professional development (CPD).*

## Introduction

There is agreement amongst researchers all over the world that teachers need to have both subject knowledge of mathematics per se, and mathematical knowledge for teaching in order to teach effectively. There is also agreement that teachers must know in detail the school mathematics they are expected to teach and a bit more, beyond the level they are assigned to teach. But ‘how much more?’ and ‘More of what?’

This body of *more* mathematics knowledge acquired through studying mathematics beyond school level is referred to in literature as ‘academic mathematics’ or ‘advanced mathematics’. Moreira and David (2008) refer to academic mathematics as that large part of the mathematics that a ‘major’ of mathematics is required to learn and which consists of that “scientific body of knowledge as produced and organized by the professional mathematicians” (p. 24). Similarly (and somehow a more influential terminology) is Advanced Mathematical Knowledge (AMK) put forward in 2009 by Zaskis and Leikin and defined as “*systematic formal mathematical knowledge beyond secondary mathematics curriculum, likely acquired during undergraduate studies*” (p.2368).

However, what and in which ways this body of knowledge of ‘AMK’ or ‘academic mathematics’ is necessary or useful to functioning effectively as a teacher of mathematics at school level is still under much debate, as there is little agreement amongst researchers worldwide about how completing these courses influences future teachers’ instruction (Zaskis & Leikin, 2010) or improves their students’ subsequent achievement in the subject (Darling-Hammond, 2000).

## **The Research Question**

This paper thus reports on a study which was aimed at investigating if and in what ways (re)engagement with relevant AMK related to a school mathematics topic, functions in particular, empowers teachers conceptually and pedagogically.

## **Theoretical Influences – brief overviews**

### **Teachers' knowledge for teaching**

The study of teachers' knowledge of subject matter and its relationship to the quality of classroom instruction has grown substantially since Lee Shulman launched a call for researching teachers' different components of a professional knowledge base for teaching (Shulman, 1986). While there is no agreement amongst the mathematics education community about the relationship between these components, research flourished in an effort to conceptualize mathematics teachers' professional knowledge base for teaching.

One of such effort which builds on and refines Shulman's (1986) initial categorization of types of knowledge of a teacher of any subject, namely subject matter knowledge and pedagogical content knowledge, and which has proven to be very to be influential is the mathematics specific framework advanced by Ball, Thames and Phelps (2008). Their Mathematical Knowledge for Teaching (MKT) framework lays the foundation for a practice-based theory for mathematical knowledge for teaching. The authors divided Shulman's second category of Pedagogical Content Knowledge (PCK) into two other sub-domains, Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT), while Shulman's third category of Curricular Knowledge (CK) was also relocated under PCK as Knowledge of Content and Curriculum.

Similarly, Shulman's category of Subject Matter Knowledge was divided into three sub-domains: Common Content Knowledge (CCK), Specialized Content Knowledge (SCK), and Horizon Content Knowledge (HCK). Recently, a few other researchers (e.g., Zaskis & Leikin 2010, Even 2011) proposed positioning advanced mathematical knowledge (AMK) as an important aspect of MKT and in the following we will briefly review these categories and how they complement each other.

### **Common Content Knowledge (CCK) and Specialized Content Knowledge (SCK)**

CCK is knowledge used in the work of teaching, but also used in ways that correspond with how it is used in settings other than teaching. SCK encompasses knowledge of mathematics needed by teachers, but not necessarily used by others, such as knowledge of a particular mathematical model or representation useful for teaching a certain concept.

Development of such SCK usually starts in teacher education programmes. Indeed, teachers acquire SCK through learning about how to use number lines, hot-air balloons or any other representations and metaphors that would enable them to teach about operations with negative numbers. For instance, while an engineer knows that the product of two negative numbers is a positive number, s/he does not need to know or give a mathematical reason for why this rule works or be able to provide a conceptually-sound explanation for the 'minus and minus make plus' metaphor. This kind of

knowledge and reasoning should be an intrinsic part of a teacher's everyday classroom teaching, knowledge of the mathematics underlying rules, approaches, representations. However, far too often the implicit assumption is that prospective teachers already know the mathematics, to include the what and the why. But this is not the case. Many studies (e.g., Tirosh, Fischbein, Graeber, & Wilson, 1999) have revealed that school teachers possess a limited knowledge of mathematics, including the mathematics they teach. The mathematical education they received, both as pupils in school education and in teacher preparation, more often than not did not provide them with appropriate or sufficient opportunities to learn mathematics relationally (Skemp, 1976) and as a result, teachers themselves may know the facts and procedures that they teach but often have little or weak understanding of the conceptual basis underlying those rules and procedures (Ball, 1990).

### **Horizon Content Knowledge**

HCK (horizon content knowledge), the third sub-domain of subject matter knowledge in the MKT framework was tentatively defined by Ball and colleagues as 'an awareness of how mathematical topics are related over the span of mathematics included in the curriculum' (Ball et al., 2008, p. 403). Defined, interpreted and re-interpreted, HCK means different things to different researchers (e.g., Ball & Bass, 2009, Jakobsen et al., 2013); what is common ground amongst these interpretations is that it is knowledge that goes beyond that included in school mathematics curriculum, that influences teaching!

Ball et al. (2008) themselves describe HCK domain of knowledge as "a kind of mathematical 'peripheral vision' needed in teaching, a view of the larger mathematical landscape that teaching requires" (p.1), including "the vision useful in seeing connections to much later mathematical ideas" (p.403). The authors acknowledged that "we do not know how horizon knowledge can be helpfully acquired and developed" (ibid, 2009, p.11)

### **Advanced Mathematics Knowledge**

While engaging with the MKT framework, Zaskis and Mamolo (2011) proposed to view HCK through the notion of viewing elementary (school) mathematics from an advanced standpoint, thus positioning advanced mathematical knowledge (AMK) as an important aspect of MKT. The notion of horizon content knowledge is given by Zaskis and Mamolo in terms of the application of the notion of 'advanced mathematical knowledge', which they define as the "knowledge of the subject matter acquired during undergraduate studies at colleges or universities" (Zaskis & Leikin, 2010 p. 264).

Wasserman (2016), and later Stockon and Wasserman (2017) narrowed down the description of AMK to knowledge outside the typical scope of what a school mathematics teacher would likely teach, in that AMK is relevant, the advanced mathematical ideas are connected to the content of school mathematics, but also that these forms of knowledge of advanced mathematics are in some way productive for the teaching of school mathematics content.

Since Zaskis and Leikin's (2009) first conceptualisation of AMK, the authors also launched a call for further research to determine whether teachers' ability to identify explicit connections between AMK and the mathematics taught in school is a rare gift of only a few teachers or whether specific prompting is needed to bring this ability to surface.

## **The study: the England, UK context**

Rather than relying on individual teachers' gift to identify explicit connections between AMK and the mathematics they are expected to teach, in this paper we propose that teachers of mathematics should be explicitly supported in becoming aware of these connections.

However, unlike other countries where teacher training is undertaken alongside undergraduate mathematics studies, and where such opportunities could be offered to prospective teachers as part of their undergraduate studies (e.g., Wasserman et al., 2017), the UK context is different. The teachers in the UK complete their training in a one-year postgraduate course, meaning that they would have studied advanced mathematics as part of their undergraduate studies not related with teacher education. Thus, for them the study of advanced mathematics had no explicit relation to school mathematics content.

Hence the study presented in this paper is a step forward in response to Zaskis and Leikin's (2009) call, but suited to the UK approach to teacher training, and where such interventions are offered to teachers after they completed their undergraduate studies, either as part of their initial teacher training postgraduate course or as a professional development opportunity after they qualify as teachers.

## **Methodology**

In this paper, I will be reporting on a two-hour CPD workshop designed to support the teaching of specific areas of the school curriculum, namely functions, and aimed at increasing teachers' familiarity with a variety of representations of functions in the school mathematics and their awareness of how these representations interconnect. The CPD workshop was designed and taught by the author of this paper, and the tasks attempted were of both mathematical and pedagogical nature, aimed at developing a deeper conceptual and pedagogical understanding of this topic, in ways suggested by research findings on ways of teaching about functions at various levels of students' education (e.g., Ayalon et al. 2013, Nardi, 2001).

Each workshop was designed to start by posing a school mathematics question or a problem situation that teachers could do but where they may encounter some difficulties in answering it correctly and completely; in order to overcome the difficulties, the teachers will be guided towards recalling/reengaging with some relevant AMK; this will then be followed by a classroom-inspired scenario, of a pedagogical nature, where the teachers will be applying their new learning and become explicitly aware how their new learning supports their teaching.

## **Data sources**

Textual data was collected through field notes that detailed some of the group interactions. Post-session written reflections were solicited and collected at the end of the session. The teachers were asked to comment on the activities in relation to their own learning, their pupils' mathematical learning, and their preparedness of teaching this topic. Written notes about the teachers' comments, questions, written work, were also made down by the myself throughout the workshop.

## The participants

The participants were eight early career teachers of mathematics attending the two-hour CPD workshop. They were practicing mathematics teachers who wanted to refresh their knowledge about functions, given the high profile of this topic in the new re-vamped mathematics curriculum in England, UK. Features of and operations with functions such as: domain, range, inverse and composite functions, which were traditionally studied by older learners (16 to 18 year old learners or even undergraduates) are now to be studied by 14 to 16 year old learners. Hence, all secondary mathematics teachers need to be able to teach this topic. The eight teachers gained their qualified teacher status as a result of studying on a one-year teacher training course. As expected, they studied some mathematics at undergraduate level: six teachers studied for mathematics degrees, one had an engineering background, while one other teacher had an economics background and introduced himself as a non-specialist mathematics teacher. Consent to collect any observational and written notes throughout and after the workshop was sought from all the eight teachers.

## Data Analysis and discussion

The workshop started by posing a school mathematics question or a problem situation that teachers could do but where it was envisaged they may encounter some difficulties in answering it correctly and completely, as suggested by previous research (e.g., Nardi, 2001). The teachers were provided with an activity which required sketching the graph of functions that shared the same rule (one such example being  $f(x) = x^2$ ), but which had different domains of definition. The teachers worked in pairs, and each pair was provided with a different domain for the function. The domains were: the whole set of real numbers, open and closed intervals, and discrete sets of real numbers. At the start of the activity, the teachers were not aware of the functions allocated to the other pairs.

*Teachers' engagement with (partial) representations of a function:* The graphs produced by each pair looked more or less the same; a smooth curve in the shape of a parabola, carefully drawn to look symmetric about the y-axis. When the graphs were shared with the whole group, the teachers became aware of the similarities, but also the differences in their tasks; despite all sharing functions described by the same rule, the domains for each function were different, and so the discussion led naturally to a discussion about what a function was.

*Teachers' re-engagement with the formal definition of a function:* In the discussion, some teachers seemed to recall having studied about the formal definition of a function in their undergraduate studies, while others did not seem to have such a recollection or even an awareness of ever encountering such a definition. In what followed, disparate suggestions from teachers were recalled and put forward such as domains, co-domains, ranges, one-to-one, correspondence, notation conventions, and with some guidance from me, they reached the formal definition of a function of one real variable, which some recognised as having encountered them in their undergraduate mathematics course.

This is evidence of teachers reaching for *more* advanced mathematics knowledge (in this case, the formal definition) related to functions, in the need to complete the task successfully. The 'starter'

activity provided them with the impetus to reach for *more* than the school mathematics they were all too familiar with. Tapping into that knowledge, and once recalled (or newly learned, in the case of two teachers) there was evidence that it supported teachers completing the activity successfully. The teachers revisited the graphs they initially produced and each pair produced different graphs: either a smooth continuous parabola, or a pointwise graph, or a piece-wise graph, depending of the given domain of definition.

Even though a few of the teachers had an awareness of the formal definition of functions and were able to recall some ‘bits’ of it, they commented that “it did not occur to me to relate this activity with the formal definition”, and “that was high level mathematics not much used after the [undergraduate] course”. The teachers seemed to be much more influenced by the current limited description of functions in the school curriculum, where domains and ranges of functions are not explicitly considered until the more advanced years of school level education.

*Pedagogical implications: developing an awareness of building up to the formal definition of a function:* The ‘starter’ activity was then followed with a discussion of how the concept of function develops in the school mathematics curriculum. Representations of functions as they chronologically appear in the school curriculum were discussed: One-to-one or many-to-one mappings, Input/output machines, Relations between particular x-values and y-values; Expressions to calculate the y-values from given x-values, and Graphs. Each time, the teachers were encouraged to relate these representations with their recalled or newly learned AMK about functions. In doing so, the teachers came to realise that each of these representations explains particular aspects/features of the concept without being able to describe it completely! And a realization that overreliance on one representations or lack of connections between such representations gives way to misconceptions when working with functions, just as pointed out by Ayalon, Lerman and Watson (2013).

Indeed, the teachers themselves became explicitly “aware of stages of building up to the definition of a function”. A teacher in particular was able to illustrate this new learning eloquently. She stated that she learned about: “Different representations of functions – I’ve always seen them as disconnected representations, but they complement each other nicely towards understanding functions” and exemplified with how in the lower secondary school curriculum, functions are portrayed as a computational process and are seen as an input-output machine that processes input values into output values. Such representation emphasizes the rule aspect in the definition of functions, seeing thus functions as an instruction to calculate one numerical set from another. This view leads to a perception of graphical representation of functions amongst pupils as points (usually with integer coordinates) plotted on the set of axes, which are then joined up with segments, with no explicit awareness that any other point lying on those segments could be just as good a candidate in the table of values. And in fact, the teacher herself realized that she never discussed or pointed this out in her teaching when plotting graphs.

*Pedagogical empowerment - addressing ambiguities in the treatment of school maths topics:* For the final task of this workshop, the teachers were asked to think about how they introduce and teach pupils of different ages about square roots. Sharing of own experiences immediately led into disputes over the numerical value of the square root of a number: a positive, a negative or a  $\pm$  value. Most teachers defended the  $\pm$  value, and attempted to justify their answers in a variety of ways: “this is

how I was taught myself”, “this is how it is presented in textbooks”, “this is how it appears in marking schemes of examination board”, “This has always been the case.” I then prompted the teachers to think about how this school maths concepts related to their learning about functions gained in the session up to that point and I suggested that perhaps it could help them settle the inconsistency in their answers.

The teachers were indeed able to call upon their recollection of the more advanced knowledge about functions (extended at this point to inverse functions and relationships between domains and ranges) and agreed on the positive answer only, despite feeling uncomfortable about dismantling a long-held belief about a piece of knowledge about square roots, they themselves inherited from their secondary school maths education and unfortunately still perpetuated by current mathematics school textbooks (Crisan, 2014).

## Concluding remarks

The teachers on this CPD course had revisited some of their AMK of functions, which provided them with a better understanding and an awareness of the developmental trajectory in learning about functions. They became aware of how representations in the school curriculum are particular instances of the concept itself, and how teaching towards a complete/full understanding of functions requires teachers to be aware of what each of these representations contribute to the complete understanding of the concept of functions: “Today’s session helped me understand how I could have addressed the [pupils’] errors and how I can clarify things in the future.”, while another teacher shared his learning in the session: “What I have learnt today? About advanced mathematics knowledge and its place in classroom and planning.”.

On a pedagogical level, AMK of functions empowered the teachers to justify why pupils make mistakes, and thus increased their knowledge for teaching this topic in the future.

The task in which the participants were involved in this workshop provided a context in which they recalled AMK related to functions, while in the case of some other teachers, they acquired new AMK (the teachers with an engineering and economics background). The teachers gained conceptually, as the mathematics tasks created some instability in what they knew about functions and their graphical representations, and in order to address the differences in their tasks, the teachers need to engage with *more* advanced mathematics knowledge of functions was brought out into the open.

However, this study has shown that even when teachers possess the AMK, they are not necessarily aware of manifestations of AMK in the school mathematics curriculum, thus they need to be supported in develop such awareness and make it explicit. One cannot simply assume that teachers will make connections without some intervention. This paper proposes that, in the UK context this should be the remit of courses preparing teachers of mathematics (either initial teacher training and/or CPD). All teachers, irrespective of their academic background, should be supported to look at school mathematics from an advanced standpoint and to examine school mathematics topics by engaging with advanced mathematics knowledge, while guidance is provided in terms of what AMK is relevant and how it informs school mathematics.

*Researchers conceptualize mathematical knowledge for teaching in different ways, but a coherent approach to the mathematical education of teachers requires teacher educators' understanding to be robust and shared. At present, we know little about how teacher educators interpret and operationalize this important domain. Our analysis of interview data indicates two sites of divergence in teacher educators' understanding. Some view this knowledge as a resource for the mathematical work of teaching, treating it as distant from actual practice, whereas others view it as a slice of the dynamic and situational work. Also, some view the mathematical work of teaching, and its knowledge demands, as detached from particulars of students and schooling, while others view this work as inseparable from student identities and the larger environments within which instruction occurs, thus integrating regard for equity. Implications are discussed.*

**Keywords:** *Mathematical knowledge for teaching, Teaching, Teacher educators.*

## Introduction

Mathematics educators and researchers agree that the mathematical knowledge teachers need is not simply advanced mathematics — it is specialized, teaching-specific mathematical knowledge. Shulman's (1986) pedagogical content knowledge continues to stimulate the field. Ma's (1999) profound understanding of fundamental mathematics exposed subtle depth in the mathematical demands of teaching. Scholars continue to expand conceptual models (e.g., Ball, Thames, & Phelps, 2008; Carrillo-Yañez et al., 2018; Rowland, Huckstep, & Thwaites, 2005; Thompson, 2015) and measures (e.g., Baumert et al., 2010; Hill, Schilling, & Ball, 2004; Saderholm, Ronau, Brown, & Collins, 2010). Although scholars agree such knowledge is important, different constructs have been proposed, with underdeveloped theoretical grounding, and measures often operationalize a specific construct in different ways (Hoover, Mosvold, Ball, & Lai, 2016).

Awareness that mathematical knowledge for teaching is specialized and teaching-specific creates an imperative for the mathematical education of teachers. Unfortunately, shifting to teaching of mathematical knowledge for teaching is not a simple matter of introducing new content. Understanding the new content is a challenge and teaching it requires different instructional practices with new demands on teacher educators. A number of researchers have begun to investigate these demands. For example, some have used records of practice from teacher education courses or professional development programs to unpack the mathematical demands of such work (e.g., Chick & Beswick, 2018; Superfine & Li, 2014; Zopf, 2010). Others have examined teacher educators' collaborative work, by either drawing from reflections on their practice (Masingila, Olanoff, & Kimani, 2018), or interviewing teacher educators directly (Zazkis & Zazkis, 2011). Each

of these efforts has focused on the connection between mathematical knowledge for teaching and the mathematical demands of teacher education.

While this investment in conceptualizing an analogous specialized knowledge for mathematics teacher education is valuable and timely work, a more basic question is whether teacher educators mean the same thing when referring to mathematical knowledge for teaching. Of course, individual interpretations vary, but meaning needs to be sufficiently shared for communication and programs to be effective. Teacher educators may believe they are each working on mathematical knowledge for teaching in their courses but could in fact be focusing on different issues. Alignment among instructional materials, courses, and instructors is crucial. As Cohen (2011) argues, absent a sufficiently shared notion of the content and aims of education (or in this case teacher education), efforts to assess and improve the quality of teaching will be much more difficult, if not impossible. In our own work with professionals concerned with the mathematical education of teachers, we have found that ambiguity often leads to individuals or groups talking past one another, even as they allegedly invest in the same content. In addition, if teacher educators' understandings of mathematical knowledge for teaching differ, then studies that seek to understand the mathematical demands of mathematically educating teachers could be scrutinizing arguably different aspects of professional practice and ignoring ambiguity that might lead to additional or different results. As the larger community of mathematics teacher educators (including mathematicians, teacher educators, and school-based personnel) learns about mathematical knowledge for teaching and becomes convinced of its importance, mixed understanding looms large.

Despite these implications, we know surprisingly little about teacher educators' conceptualizations of mathematical knowledge for teaching. In this study, we analyze interviews with teacher educators to better understand their thinking, and in so doing, we contribute to the growing literature on the teaching of mathematical knowledge for teaching.

## **Conceptual and contextual background**

Before laying out the particulars of our study, we briefly describe the study context and the perspectives we bring to our analysis. Our team relies on a conception of mathematical knowledge for teaching that understands knowledge to be embedded in teaching and considers specialized content knowledge to be mathematical knowledge unique to the work of teaching (Ball, 2017; Ball et al., 2008). We conceptualize teaching as the management of interactions of instruction in environments (Brousseau, 1997; Cohen, Raudenbush, & Ball, 2003; Jaworski, 1994; Wickman, 2012). In this, we understand attention to equity to be inherent to teaching that is educative and consequently to be inherent in the dynamic mathematical work of teaching. We understand equity in the sense of both “reasonableness and moderation in the exercise of one’s rights, and the disposition to avoid insisting on them too rigorously” as well as “recourse to general principles of justice (the *naturalis æquitas* of Roman jurists) to correct or supplement the provisions of the law” (Equity, 2018). For this study, we are interested in the many different ways that equity might be considered in teaching and the mathematical dimensions and demands of this work.

As a means of building capacity among teacher educators concerning specialized content knowledge, our team has run a series of workshops that bring together different professional

communities with the purpose of collectively creating tasks for teachers that address specialized content knowledge. Workshops are organized around a cycle of constructing, discussing, and reviewing tasks. Whereas some of our previous projects have focused on developing multiple-choice items for assessment or measurement purposes, we have adopted a more inclusive interpretation of task type in the present workshops with the intention of using task development as a tool for building understanding and instructional materials.

In the first year of the project, four workshops were held. Each consisted of roughly 30 to 50 participants. Some participated in more than one workshop, but over 150 professionals participated in at least one. They came from over 25 states of the United States, as well as Brazil, Canada, Norway, Turkey, and Iran. Their professional roles varied. Some were higher education faculty from mathematics departments and schools of education. Some were professional developers, teacher leaders, curriculum specialists, or other school-based personnel. Some were state leaders. All were involved in the mathematical education of teachers. Consistent with discussions above, our framing of specialized content knowledge at the workshop emphasized that the mathematical work of teaching requires coordination of pedagogical and mathematical entailments while simultaneously attending to, and acting against, patterns of marginalization and inequity.

Our aim is to understand how those responsible for the mathematical education of teachers understand mathematical knowledge for teaching and the extent to which they shared a coherent vision of it. The design of our study is to examine differences in understanding among our participants. We acknowledge that our workshop participants constitute a limited sample of professionals engaged in the mathematical education of teachers. They have likely read some of the same research, self-selected to attend our workshop, and listened to our workshop framing of mathematical knowledge for teaching and task development. This suggests that they may hold more similar views than those held in the broader community. We argue that, because we are examining differences among participants, our sample may actually strengthen our claims, revealing patterns that are likely alive and well in the broader professional community.

## **The study**

To investigate teacher educators' understanding of specialized content knowledge, we interviewed 13 teacher educators after the fourth workshop, held in July 2017. These interviewees varied in terms of demographics, number of workshops attended, professional affiliation, perceived fluency with the ideas, etc. Interviews were conducted via video conferencing and recorded. In addition to probing their experiences at the workshops, we asked explicitly about their views of specialized content knowledge, teaching, and equity. To elicit interviewees' understanding of specialized content knowledge, we asked them to comment on a recording of a discussion that occurred at the workshop. The focus of the workshop discussion was a video of teaching where a Black girl named Aniyah is called to the board to show  $\frac{1}{3}$  on the number line (see Ball, 2017 for analysis). The aim of the workshop discussion was to use the classroom video as a seed for developing specialized content knowledge tasks. The aim of viewing the workshop discussion in the interview was to provide a context for expressing understanding of mathematical knowledge for teaching.

After the interviews were completed, a larger team of seven researchers processed the data, created collective summaries of the interviews, and decided on four cases to highlight in this paper. The four chosen, Paula, Alyssa, Ranesh, and Daniele (names are pseudonyms), provided a spectrum of different roles and of different perspectives visible in the 13 interviews (Table 1). The larger team also piloted preliminary frames and coding schemes and developed an approach using the instructional triangle to categorize components of the mathematical work of teaching evident in participants' responses. The first two authors then created detailed characterizations (individually, then jointly reconciling differences) and identified common patterns. It should be noted that our goal here is not to say something about the effects of the workshop but rather to unpack how participants understand the construct.

## Results and discussion

Our preliminary analysis of interview data revealed two divergences in teacher educators' understanding of specialized content knowledge. The first relates to the nature of such knowledge and its connection to the mathematical work of teaching. The second relates to the relationship between such knowledge and regard for equity, in particular regard for the development of students' identities and the larger environments in which instruction occurs.

<i>Interviewee (Role)</i>	<i>Nature of knowledge</i>	<i>Regard for equity</i>
Paula (Math education faculty)	Static, stable, prerequisite resource	Not integrated
Alyssa (K-12 school-based)	Dynamic, situational slice of work	Integrated
Ranesh (Math faculty)	Dynamic, situational slice of work	Partly integrated
Daniele (Math education faculty)	Partly dynamic	Not integrated

**Table 1: Summary of interviewees**

### Nature of knowledge

The first site of divergence lies in how teacher educators understand the nature of specialized content knowledge. For example, Paula often collapsed real-time decision making with particular students and particular settings with the kind of work that one might do outside the classroom, independent of those students and settings. Although she insisted that teachers need to be able to see what each student knows and understands, at times, her focus was squarely on knowledge that is *required for teaching*. In particular, when Paula spoke about her attempts to assess such knowledge, she referred to it as something teachers “need to know” in order to be an effective teacher, rather than speaking about specialized content knowledge as something present in (and arising from) particular demands in teaching. It seems as though, for Paula, having particular knowledge outside the classroom ensures success inside the classroom. This kind of conceptualization of the mathematical work of teaching is consistent with a didactical or instructional triangle that ignores certain bidirectional interactions between the vertices. Thus, students, environments, and content often did not seem to affect the kinds of mathematical work that Paula envisioned for the teacher.

Several other participants drew clear lines between knowledge and knowledge-in-use but viewed both as essential to teaching well. For example, while Alyssa contended that “teachers need broad knowledge of content” as well as “a really specific knowledge of mathematics” in order to “see what kids are doing, to see how kids are accessing problems”, she distinguished this knowledge from that which is embedded in the mathematical work of teaching. For her, the mathematical work was “what [teachers] are doing with that knowledge, and what they’re doing with the data they are gathering in the moment...like how they are facilitating a classroom environment with that understanding.” She also referred to how “content knowledge empowers [teachers] to make ... strategic real-time decisions with the information they have.” Similarly, Ranesh also considered specialized content knowledge to be related to, but distinct from, the mathematical work of teaching. In his interview, he spoke about how the mathematical work of teaching was about “knowing *what* to do, and *how* you would do that in the classroom.” In his view: “SCK is the noun, and the mathematical work as a teacher ... that would be the verb.” In their interviews, Ranesh and Alyssa each seemed to pay more attention to the dynamic interactions present in instruction and this focus seemed to help them make a distinction between knowledge and knowledge-in-use. From their perspective, specialized content knowledge is necessary, but not sufficient for successful execution of the mathematical work.

Our analytic framing of teaching as management of interactions among teachers, students, content, and environments suggests that teacher educators’ views of mathematical knowledge for teaching differ in sophistication. In particular, Paula’s view of it as static, stable, prerequisite knowledge overlooks certain interactional pairings central to teaching. In contrast, Alyssa’s and Ranesh’s view of it as a dynamic, situational slice of work reflects their fuller understanding and skill in thinking about the full range of interactions central to teaching.

### **Mathematical knowledge for teaching and integration of student identities and environments**

A second site of divergence is the extent of integration of equity concerns, in particular student identities and environmental factors, into mathematical knowledge for teaching. Alyssa, for example, when shown specific instances of teaching, referenced the larger environments in which instruction occurs and how the mathematical work in those moments is shaped by such considerations. For instance, when commenting on the record of practice referenced in our interview, Alyssa highlighted how the teacher calls upon “a student like Dante” at a particularly crucial moment in a class discussion about naming fractions on the number line. In the video, several other students had each put forward correct pieces of the final answer (one solution drew attention to the need for equal partitioning of the whole, while another correctly identified the whole as the unit interval from zero to one) but each student had a different incorrect answer on the board. Dante also did not have the correct answer in his notebook, but when he is called on, he attempts to articulate his thinking and goes on to ask a question about how the previously presented solutions relate to each other. Alyssa described this moment as an act of empowerment for Dante (a Black student in the classroom video being discussed in the workshop video) and declared that the teaching move allows Dante to be a “bearer of mathematical knowledge”, a position not typically offered to students “like him” (perhaps referencing how non-standard responses of Black boys are often interpreted). She also asserted that calling on Dante at this moment does more than just

empower a particular student, it also disrupts systemic patterns of injustice and racism. Alyssa explicitly connected this idea to the mathematical work of teaching, maintaining that, “part of the work of teaching is knowing your students and knowing how to strategically call on students at set times.” Even though it is apparent that Dante is “a student who understands quickly and is good at synthesizing other people’s thoughts”, she believes many teachers would not choose to call on him in that moment, especially since he does not have the correct answer. However, Alyssa contended that the teacher in the video intentionally “*creates* the situation where a student like Dante could then say, ‘what is the connection?’” and she saw this mathematical and pedagogical work as intertwined with issues of equity. Through her comments, we see concerns for each of the components of the instructional triangle — mathematics, teachers, students, and environments — as well as their interactions. Her regard for equity in relation to the mathematical work of teaching is coincident with her mutual consideration of the intertwined interactions of teaching.

By contrast, in her interview, Daniele seemed to acknowledge the general possibility that student identity and patterns of systemic inequity can interact in ways that shape the mathematical trajectory of a class, but admitted that she does not think much about equity in her own work. When asked about the video of the workshop discussion, Daniele remained focused on mathematical content and failed to consider comments about how Dante’s race/ethnicity shapes the kind of mathematical work the teacher must do in that moment.

Daniele never mentioned Dante’s identity as a Black boy as something that might relate to the mathematical work of teaching. Instead, Daniele suggested that calling on Dante was a way of including other students in the class discussion and gaining access to their thinking. She explained the teacher’s choice to call on Dante in the following way:

We think about the students that are maybe up in front talking, but that’s not the whole class. That’s only two students in the class and it’s a large class. And so, what are the other students doing and thinking about? And we think about the behavior issue, and that stands in the forefront, but if we really actually listen to kids that have behavior issues potentially ... then we can think about well what is Dante saying and how is *he* thinking about this task?

Viewed in this light, the teacher might have called on any particular student at that moment rather than Dante specifically. For Daniele, the only things about Dante that seem to be relevant for the work of teaching are his particular classroom behaviors and the mathematical concerns he raises. Daniele’s comments are fundamentally about the content of Dante’s questions rather than Dante as an individual or about the environments that shape both his identity and the work of teaching. Daniele seemed to be articulating that issues of equity are not embedded in the work of teaching, but are an optional add-on — something that is not central. This conceptualization of the mathematical work of teaching, is consistent with an instructional triangle would have little or no interaction with particulars of the environment.

Again, our analytic framing of teaching as management of interactions among teachers, students, content, and environments suggests that teacher educators’ integration of concerns for student identities and environmental factors with mathematical knowledge for teaching differ in sophistication. In particular, Daniele’s disregard for student identities and environmental factors in

her consideration of mathematical issues contrasts with Alyssa's nuanced consideration of their import for the mathematics at hand.

## Conclusions

As the instructional triangle emphasizes dynamic interactions among teachers, students, content, and environments, it seems natural that such a framing would draw out the absence or presence of dynamic interactions. But it is clear that certain interactions are more uniformly understood than others (at least within our data). None of the teacher educators we interviewed could be characterized as not attending to the dynamic interaction between teacher and mathematical content. This is significant given observed divergences. The two primary divergences we found thus say something important about the ways in which teacher educators understand mathematical knowledge for teaching. They suggest sites where a shared conceptualization breaks down or areas where there is considerable variation in understanding. These may be fundamentally different conceptualizations, built on different foundations, or they may be developmental issues related to their understanding of teaching. Regardless, we suggest that appreciating differences in these conceptualizations and being able to name and talk about constituents of teacher educators' understandings are useful building blocks for the field.

*Extant research on the teachers' knowledge includes limited studies focusing on teachers at university level. In this work, based on the Mathematics Teacher's Specialised Knowledge (MTSK) model and through an instrumental case study, knowledge of a lecturer in a real analysis course for prospective mathematics teachers is analyzed. We exemplified lecturer knowledge in different subdomains of the MTSK model. These results contribute to the understanding and characterization of the components of mathematics teacher's specialised knowledge at the university level.*

*Keywords: lecturer knowledge, specialised knowledge, university level, real analysis, real numbers.*

### Introduction

The mathematics education research focusing on the teachers' knowledge has traditionally been conducted at the elementary and secondary level. However, the study of mathematics lecturer's knowledge has recently emerged as a line of research that seeks to understand this knowledge, its development, and how it is reflected in university teaching practices (Biza, Giraldo, Hochmuth, Khakbaz, & Rasmussen, 2016). Among the scarce account of research about mathematics lecturer's knowledge, the work of Breen, Meehan, O'Shea, and Rowland (2018) is a first approximation of teaching at the university level using Knowledge Quartet model (Rowland, Huckstep, & Thwaites, 2005). In addition, the studies conducted by Vasco, Climent, Escudero-Avila, and Flores-Medrano (2015) and Vasco and Climent (2017) highlight the utility of the Mathematics Teacher's Specialised Knowledge model (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013) and its corresponding analytical categories for understanding mathematics lecturers' knowledge. Other research in the same line, indicate that it is important to obtain empirical evidence pertaining to the components of specialised mathematics lecturer's knowledge (Delgado-Rebolledo & Zakaryan, 2018) and deepening the understanding of these components in situations other than lecturers' classroom practices (Vasco & Climent, 2018).

Taking into account this background, we propose the following research question: Which knowledge, according to the Mathematics Teacher's Specialised Knowledge model, arises in the teaching practice of a mathematics lecturer? Teaching practice is considered in a broad sense, including lesson planning, liaising with colleagues, giving lessons, and taking time to reflect on them afterwards (Carrillo et al., 2018). In this sense, with the aim of answering the research question, we have studied one mathematics lecturer teaching a real analysis course in a mathematics teachers' training program, and reflecting on his performance. In this paper, we present examples of the different subdomains of this lecturer's specialised knowledge. We do not consider his characteristics as a mathematics teacher educator. A discussion about mathematics teacher educator's knowledge is exposed in the paper of Almeida, Ribeiro and Fiorentini (in this volume).

## Theoretical Framework

In the Mathematics Teacher's Specialised Knowledge (MTSK) model, two domains of teacher knowledge are distinguished, Mathematical Knowledge (MK) and Pedagogical Content Knowledge (PCK). The model also considers teacher's beliefs about mathematics and about mathematics teaching and learning (Carrillo et al., 2018).

MK refers to teacher knowledge of mathematics within the educational context, considering some of its characteristics as a scientific discipline. MK includes the Knowledge of Topics (KoT), Knowledge of the Structure of Mathematics (KSM) and Knowledge of Practices in Mathematics (KPM) subdomains. KoT contains knowledge about definitions, properties and their foundations, procedures, registers of representation, phenomenology, and applications (e.g., knowledge of the field properties of rational numbers; knowledge of definitions of real numbers). KSM encompasses knowledge of connections among mathematical items: connections associated with an increase in complexity or with simplification, and inter-conceptual connections (e.g., knowledge of relationships between infinity and the Archimedean property of the real numbers). KPM comprises knowledge about demonstrating, justifying, defining, making deductions and inductions, giving examples, and understanding the role of counterexamples (e.g., knowledge of how to prove the density property of the rational numbers in real numbers).

On the other hand, PCK is a specific type of knowledge of pedagogy in which the mathematical content determines the teaching and learning that takes place. PCK includes the Knowledge of Mathematics Teaching (KMT), Knowledge of Features of Learning Mathematics (KFLM), and Knowledge of Mathematics Learning Standards (KMLS) subdomains. KMT includes knowledge of theories of mathematics teaching, teaching resources, and strategies, techniques, tasks, and examples (e.g., knowledge of particularities of a real analysis textbook that makes it more convenient than others for use in a course, or use of analogy to illustrate the features of the existential quantifier). KFLM comprises the knowledge of theories of mathematical learning, strengths and weaknesses associated with learning, ways in which students interact with mathematical content, and emotional aspects of learning mathematics (e.g., awareness of analysis being more difficult for students than calculus; knowledge of difficulties students encounter when working with real numbers). Finally, KMLS contains the knowledge of sequencing of topics, expected learning outcomes, and the expected level of conceptual or procedural development (e.g., the sequencing of the completeness theorem topics, characterization of the greatest element, and the Archimedean property of the real numbers).

## Methodological aspects

In this research, based on an interpretive paradigm and a qualitative methodology, an instrumental case study (Stake, 1995) was conducted. The case pertains to a lecturer and mathematics researcher that was developing a real analysis course. Real analysis is a second-year course in a mathematics teachers' training program in a Chilean university. In the first two years, the students take calculus, algebra, and geometry courses, whereas, from the third year, the courses focus on teaching practices, general pedagogy, and didactics of mathematics (numerical systems, functions, geometry, and statistics).

The lecturer, who will be called Diego, has more than 20 years of teaching experience at the university level and this is the sixth time in recent years that he has developed the real analysis course. Diego's classes are of 90-minute duration, and each was videotaped, transcribed, and organized in class episodes according to Diego's tacit or explicit goals. For example, we consider a *class episode* the period since Diego begins until he finishes presenting a definition. In each episode, Diego's interventions that show knowledge according to the MTSK model (a knowledge that could be classified in an analytical category of some subdomain of the model) are chosen as *analysis units*. The analysis units that allow us to affirm the presence of a teacher knowledge were named *evidence*. Others, where we suspected the existence of teacher knowledge, but additional information was needed in order to confirm or refute this suspicion, were denoted as *indication*. An indication provided a reason to investigate in more detail the lecturer's knowledge. Hence, the differentiation between evidence and indication (Moriel-Junior & Carrillo, 2014) is considered with the aim to refine our interpretations and deepen the understanding of the subdomains of lecturer's knowledge.

The data obtained through video recordings was complemented with a semi-structured interview that was divided in two sessions for a total duration of three hours. The interview was audio-recorded and subsequently transcribed, reproducing Diego's speech with the highest fidelity possible. A template of questions was constructed to prompt Diego to think about some of his expressions and performances during the classes. For example, in one of Diego's classes, he referred to a YouTube video as a complementary material. Thus, in the interview, we asked Diego why he used that video and what was its intended objective. In addition, some questions were formulated with the intention to examine indications of knowledge and to explore the subdomains of specialised knowledge that has not been present in class episodes. Video clips of the classes were shown to stimulate Diego's recollection, because the interview was conducted once the course was completed. Transcriptions of the interview were analyzed in a similar manner to classes, considering each response to a particular question as an analysis unit.

## Results

In this section, we exemplify with evidence the subdomains of Diego's specialised knowledge during a class session on real numbers. Diego starts this class by enunciating some concepts and properties studied in the previous class, such as the least-upper bound property and the Archimedean property of real numbers. Next, he uses these elements with the aim to construct, together with the students, the density of the rational and irrational numbers in the real numbers proof.

### Diego's mathematical knowledge

As a part of his KoT, Diego knows axioms for the real numbers, constructions of this numerical system (e.g., Cauchy sequences or Dedekind cuts), definition of real numbers as a complete ordered field, and properties of real numbers. For example, Diego *knows the Archimedean property of the real numbers* (KoT) because he enunciates the property ( $\forall x, y \in \mathbb{R}, x > 0, \exists n \in \mathbb{N}$  such that  $nx > y$ ) and comments on that in the following way:

Diego: And, this property, which was not specified by Archimedes, but Euclid, is equivalent to saying that, for all small natural number  $\varepsilon$ , there exists a natural number  $n$  such that  $1/n \leq \varepsilon$ .

Later, Diego writes on the blackboard the following proposition: Let  $a_n < b_n$ , and  $I_n = [a_n, b_n]$ , if  $I_n$  is a set of closed and bounded intervals, there exists  $x \in \mathbb{R}$ , such that  $a_n < x < b_n$ ,  $\forall n \geq 1$ . Next, he makes a comment regarding this statement.

Diego: This proposition indicates that, every time that I intercept closed and bounded intervals, that are nested... I forgot to say that they have to be nested, if not, it is not true. If the intervals are not nested, then the intersection is empty. For example, if you take the  $[0,1]$  interval and later the  $[10,12]$  interval, in the intersection you will have nothing because they are not nested. Then, to say that they are nested, I add to the proposition [writes on the blackboard,  $\forall I_n \supset I_{n+1}$ ]

Diego *knows the nested intervals property* (KoT), and deepening his discussion on the property, he emphasizes that the intervals must be nested in order to have an intersection that is not empty. Also, he understands how this sufficient condition gives sense to the implication expressed in the property. This *knowledge of use of formal language* as a way of communicating the mathematical idea expressed in the nested intervals property, belongs to the KPM subdomain.

On the other hand, starting from an indication of Diego's knowledge about the importance of the density of  $\mathbb{Q}$  in  $\mathbb{R}$  property, in the interview, when we asked Diego about the meaning of this property, he responded as follows:

Diego: The density is everywhere, because you cannot do anything if you do not have a dense and numerable set. The fact that the rational numbers are dense in the real numbers is very important, because you can take any real number and approximate it by a rational number. The real numbers have a cardinality greater than aleph 0, so you cannot count using them...Then, in this process of approximation, the rational numbers are important because, in practice, our calculations are limited to rational numbers.

In this excerpt, Diego demonstrates his *knowledge of a connection to items within the same topic* (KoT) because he points out that properties of  $\mathbb{Q}$  such as its density in  $\mathbb{R}$  and its numerability are essential to work approximation and calculation processes with real numbers. When the lecturer said, "*in practice, our calculations are limited to rational numbers*", he referred to the processes mentioned above, which are also important in applications of mathematics, such as in modelling or numerically solving differential equations. In this sense, Diego's knowledge of uses and applications of properties of  $\mathbb{Q}$  is identified as a part of his KoT subdomain.

Likewise, Diego refers to the density property of the rational and irrational numbers in real numbers. Given an interval  $[a, b] \in \mathbb{R}$ , it holds  $\mathbb{Q} \cap [a, b] \neq \emptyset$  and  $\mathbb{R}/\mathbb{Q} \cap [a, b] \neq \emptyset$ . Diego particularizes the proposition for the case of an interval with  $a = 0$  and  $\varepsilon = (b - a)/2$ . Using the Archimedean property, he establishes the following lemma: Given  $\varepsilon > 0$ , and  $n, m \in \mathbb{N}$ , the interval  $(0, \varepsilon)$  contains a rational number  $1/n$  and an irrational number  $\sqrt{2}/m$ . Hence, Diego shows his *knowledge of establishing preliminary results to facilitate the development of the density of rational numbers in real numbers proof*. This knowledge of a way of proceeding in mathematics is a part of Diego's KPM. Moreover, Diego considers the case of a positive rational number  $a$ , extending his previous

arguments, and demonstrates his knowledge of *process of particularization and generalization of a proposition* about real numbers (KPM) as a way of proceeding in mathematics.

Continuing with the development of the density of the irrational numbers in real numbers proof, the lecturer expresses:

Diego: Using the previous lemma, there exists a number  $z$ , real and not rational number, such that  $z$  is between  $0$  and  $\varepsilon$ . Then, if I add  $a$  to this inequality, I have [writes on the blackboard  $a < a + z < a + \varepsilon < b$ ].  $a$  is a rational number and  $z$  is an irrational number, then, where is  $a + z$ ? . . . If I can argument that  $a + z$  is not in  $\mathbb{Q}$ , then I can find an irrational number in  $[a, b]$ . Why is  $a + z$  not in  $\mathbb{Q}$ ? Because, if  $a + z$  was a rational number and I add another rational number, I will have to obtain a rational, because the rational numbers are a field. So, when I add two rational numbers, the answer is a rational number. Then, what can I add to  $a + z$ , conveniently, to get a contradiction?

Student:  $-a$

Diego: Ok, if I add  $-a$  to the inequality, the addition  $-a + a + z$  is equal to  $z$ . That should be a rational, but I know that this is not true, so  $a + z$  cannot be a rational number. Ok, I win.

In this episode, lecturer's knowledge of ways of validating in mathematics is identified. Diego demonstrates his knowledge of *how proofs by contradiction method are done* (KPM). The lecturer understands the logic underpinning this method of proof because he exposes what should be assumed ( $a + z$  is in  $\mathbb{Q}$ ), how a contradiction is constructed (adding  $-a$  conveniently considering properties of the rational numbers) and what must be concluded ( $a + z$  is not in  $\mathbb{Q}$ ).

### Diego's pedagogical content knowledge

Regarding Diego's PCK, in the class, Diego referred to the textbooks that he uses to develop the course. Later, in the interview, Diego elaborated on the reasons behind this literature selection.

Diego: In the real analysis course, I use the Spanish edition of a famous textbook; the original edition is in Portuguese, but in Spanish, it has two editions, detailed and summarized. I do not use the detailed version because that textbook has a lot of information. Instead, I use the summarized edition that provides the most essential parts and, if I am lacking something, then I complement it with other textbooks.

In the exposed fragment, we observe that Diego not only knows both editions of the analysis textbook (detailed and summarized), he also knows the specific characteristics of each one, which allows him to select the textbook that makes it more convenient to develop the real analysis course. This knowledge of the *teaching resource* belongs to Diego's KMT subdomain.

Likewise, Diego exposes the reasons behind the use of YouTube videos as a complementary material to the classes.

Diego: I like these videos because they are produced by the author of the textbook that we use in the course. The teacher worked in a prestigious university in Brazil and these

videos are from a course intended for postgraduate students. The course duration is two months. I present the course [the same content] in a semester, with more time and I share the videos with the students, although the videos are in Portuguese and the language could be a problem.

Diego highlights the advantages of YouTube videos (they are created by the textbooks' author and he can develop the content in more detail). However, Diego knows that this digital resource has the limitation of language that is unfamiliar for some students. In this sense, Diego shows his knowledge of the advantages and limitations associated with the videos as a *digital teaching resource*. This knowledge is included in Diego's KMT subdomain.

On the other hand, an indication of Diego's knowledge was confirmed in the interview when Diego talked about students' understanding of the real numbers.

Diego: The trouble with real numbers is the least-upper bound property, a historical difficulty that comes from Greeks. To humanity, it took more than 2000 years to comprehend the continuum . . . and maybe more, because I say until Newton, but actually, the formulation comes from Weierstrass. Then, this difficulty, this epistemological obstacle, inevitably emerges when you talk about real numbers.

Diego knows *students' weaknesses pertaining to the understanding of real numbers* (KFLM). He explains this issue considering historically intrinsic difficulties in conceptualizing real numbers due to the presence of the continuum as an epistemological obstacle.

Linked with the above, Diego comments:

Diego: The other issue is that, in high school, real numbers are reduced to an algorithmic point of view only. I do not claim that this is wrong, but it should not be restricted to only that.

In the previous statement, Diego shows his knowledge of how are taught real numbers in high school. He refers to "*an algorithmic point of view*" highlighting deep level regarding the approach given to real numbers in learning standards in some Chilean high schools. This knowledge of *the expected level of procedural development* belongs to Diego's KMLS subdomain.

## Final remarks

In this research, we have shown some examples of how the mathematics teacher's specialised knowledge could be identified and characterized in the case of a mathematics lecturer. In the pedagogical content knowledge, we exemplified the three subdomains (KMT, KFLM, and KMLS) and in mathematical knowledge we exemplified the KoT and KPM subdomains. Evidence of KSM was not supported by our findings in line with the results reported by Vasco et al. (2015). However, we obtained some indications of knowledge which supply several ideas to deepen in the KSM in the case of mathematics lecturers. Furthermore, descriptors of KPM regarding ways of communicating and ways of validating in mathematics are exposed in this work. Descriptors about ways of proceeding and ways of validating were reported by Delgado-Rebolledo and Zakaryan (2018), although the descriptors' grouping into categories is still under study. Establishing categories of KPM is an important topic of research in the MTSK model, and descriptors obtained in this study focusing

on one mathematics lecturer are a good starting point for investigating components of this subdomain in teachers at other educational levels, given that scarce evidence of KPM has been reported in the research literature (Zakaryan & Sosa, 2019).

Additionally, in some examples, we observed possible relationships among the subdomains of knowledge. For instance, when the lecturer exposes the nested intervals property, his KPM regarding use of formal language allows him to understand this property in his KoT. Also, in the lemma used to develop the density of the irrational numbers in the real numbers proof (KPM), the lecturer relies on his knowledge of the Archimedean property (KoT). In a similar manner, relationships within pedagogical content knowledge domain could be established. For example, the lecturer ascribes students' weaknesses to the epistemological obstacle associated to real numbers, which allows him to understand the procedural approach to this notion in high school. Then, when the lecturer refers to the approach to real numbers adopted in high school (KMLS), he also demonstrates his awareness of students' weaknesses when working with real numbers (KFLM).

Thus far, relationships between disciplinary knowledge and pedagogical content knowledge have been reported in studies of secondary teachers (e.g., Sherin, 2002). We propose that this type of relationships could also be established in the knowledge of mathematics lecturer. These relationships are an opportunity to investigate the development of lecturer's mathematical and pedagogical knowledge.

In line with the above, the identification of the mathematics lecturer's specialised knowledge contributes to understand mathematics lecturers' knowledge and how this knowledge is reflected in their teaching practice (Biza et al., 2016). However, more research is necessary to deepen the understanding of the nature and the components of mathematics lecturer's knowledge. In this sense, we propose to explore the relationships between the different subdomains of mathematics lecturer's knowledge as a topic for further research.

## **The probability subjective view: developing teachers' knowledge to give sense to students' productions**

Rosa Di Bernardo<sup>1</sup>, Maria Mellone<sup>2</sup>, Ciro Minichini<sup>3</sup> and Miguel Ribeiro<sup>1</sup>

<sup>1</sup>State University of Campinas Brazil; rosadibernardo92@gmail.com, cmribas78@gmail.com

*Keywords: Probability, teacher's interpretative knowledge, teacher education.*

In the last years, the importance of probability in the context of teaching mathematics is increasing together with its weight in the International Assessment Project. In particular, the presence of the content of “uncertainty and data” in the PISA framework has motivated the trend toward the relevance of this topic in the mathematics curricula all over the world. The epistemological peculiarities and the difficulties related to teaching and learning probability, is also related with the complexity to catch the differences and, at the same time, the intrinsic coherence between the three different approaches to be considered within such topic. This crucial aspect puts probability in a core position within the topics to be focused on researches in the Mathematics Education field. In particular, the subjectivist approach (de Finetti, 1931), hailing a subjective judgement influenced by a person's information and knowledge, is hardly considered in the international panorama of the school curricula, as stressed by Batanero (2015): “the subjective view, that takes into account one-off decisions, which are frequent in everyday life, and where we cannot apply the frequentist view, is hardly considered in the curriculum” (p. 43). Furthermore, we can recognize in the subjectivist approach to probability a powerful link with the psychological and cognitive attempt to measure the degree of reliability that an event occurs in the form “how much I am minded to bet on it”. Following the perspective pointed out by Batanero (2015), the subjective view of probability could support the teachers in designing meaningful educational contexts in this topic. Indeed, it is well known that teachers' knowledge has a great impact on pupils' knowledge/learning and it is essential to focus on teacher education if we want to improve pupils' learning. To make this possible, it is necessary to think about what kind of tasks in teacher education can be conceptualized and implemented in order to support teachers in developing knowledge about probability that includes also the subjective approach to it. Starting from these premises we present here a task, that is a part of a wider research project that has the goal to conceptualize and to implement tasks for teacher education in the context of probability. With this task we want to address a first research question that is: which kind of difficulties or potentialities do teachers show during the work with this task?

The task was conceptualized including pupils' productions, in order to develop the so called teacher's Interpretative Knowledge (Ribeiro, Mellone, & Jakobsen, 2016). The Interpretative Knowledge allows teachers to give sense to pupils' productions, even if such productions are considered as “non-standard, adequate answers that differ from those teachers would give or expect, or answers that contain errors” (Mellone, Tortora, Jakobsen, & Ribeiro, 2017, p. 2949). In this frame we would like to address a second research question: What kind of interpretative knowledge teachers need to recognize crucial elements to re-design the class work according with pupils' knowledge?

In particular, the task we are referring is conceptualized starting from a practice-based approach, that means to assume that teacher education should be in a direct relationship with practice. One of the ways of achieving this aim is to include pupils' productions to be discussed in the task. In particular, in this case we insert some pupils' productions came from previous research developed by the first and third authors in a fourth grade (Di Bernardo, 2017). During such research, one of the activities

**Figure 1: bar graph from previous research**

developed was to involve pupils in a measuring process of the length of a set of spaghetti out of a commercial box (about 1000 of spaghetti) and representing the outcomes by a bar graph (Figure 1). The subjective approach of probability was faced using a betting game. In fact, after the measuring activity, the pupils were invited to imagine a game in which they had to guess the length of a spaghetti randomly extracted from the box they were took off during the measuring activity. To do that, pupils were divided into two groups: *i*) the group of bookmakers, who had to create “quotas” for each event; *ii*) the group of players, who had to choose their preferred bookmaker and bet on the chosen event. We hypothesized that the pupils can use the previous representation by the bar graph evaluating in a qualitative way the inverse relationship between the frequency of a length with the “quotas” they are available to pay for a betting on this length. Starting from this educational path, we built the task for teacher education. In the first part of the task we asked teachers to create “quotas”, on the base of the bar graph in fig.1. The request was quite open in order to leave teachers free to attribute quotas for the precise measure or in terms of ranges of measures, and to express it in additive or multiplicative way. Therefore, they had to decide “how many times” to pay the player's stake both in case the player bets on a precise measure of the length of the spaghetti and in the case the player bets on a range of measure of the length of spaghetti.

*In didactic literature there are many practical materials to use experiments in mathematics classroom. Even though, experiments seem to be beneficial in mathematics education, little is known about what teachers think concerning this method. In this explorative study we want to examine the teachers’ beliefs about experiments and which relations they see between experiments and mathematics. We asked teachers from various school types in Germany, with an open-ended questionnaire. Our results indicate that most teachers see experiments either as controlled and planful procedure or as “trial and error”. Furthermore, teachers state mainly two relations between experiments and mathematics.*

*Keywords: Experiments, teachers’ beliefs, grounded theory*

## **Introduction**

Despite the fact, that teachers’ beliefs have been of increasing interest in educational research, the lack of a common shared definition or understanding of beliefs is obvious (Pajares, 1992; Philipp, 2007). Most authors locate beliefs within the affective domain but attest beliefs to be more cognitive and stable than attitudes and emotions (McLeod, 1992; Philipp, 2007; Hannula, 2012). We refer to beliefs as “Psychologically held understandings, premises, or propositions about the world that are thought to be true” (Philipp, 2007, p. 259). It has been proven that beliefs influence teachers’ activity (Grigutsch, 1996). Thus, beliefs are the basis for later actions and are part of the teacher's professional knowledge (Kuntze & Reiss, 2005).

However, during the last years the focus of interest has changed from rather global beliefs to domain specific beliefs or beliefs concerning single methods (e.g. Eichler & Schmitz, 2018). One method, that has not been taken into account so far, are experiments or hands-on laboratory activities. Since experiments play an important role in both scientific mathematics and mathematics education, we want to shed light on teachers’ beliefs concerning the nature of experiments and the relations between experiments and mathematics.

## **Experiments**

Experiments play a crucial role in the epistemology of nature science. The experimental testing of hypotheses, which have been derived from theories, can be seen as the core of scientific work in subjects like physics and chemistry. It is, therefore, not surprising that experiments have an outstanding position in science education as well. For example, in physics lessons experiments and laboratory work fill about 30% of the time spent in class (Tesch & Duit, 2004). Before illustrating the role of experiments in mathematics we will give a brief overview of the discussion about the question what exactly an experiment is.

## Characteristics of Experiments

It is rather surprising that there is no common shared definition of experiments. Borba and Villarreal (2005) summarized definitions from several dictionaries concluding that “in an experiment, conditions or factors are manipulated and facts are observed in order to prove or disprove a given hypothesis” (p. 66). They added that besides the testing of hypotheses, experiments can be used to “discover something unknown [...] or to provide examples of a known truth” (p.66). Ganter and Barzel (2012) stress that experiments form a cyclical process, starting with a concrete hypothesis, the planning of an experiment and followed by the performing of the experiment itself and analysing the results – which themselves can lead to a following cycle. It should not remain unmentioned that in every day sense – and even in some dictionaries – every hands-on activity or laboratory work is considered to be an experiment, even if the process is not controlled and follows rather the principles of “trial and error” (Borba & Villarreal, 2005).

## Experiments and (the Learning of) Mathematics

Even if it is not often mentioned or recognized: experiments and empirical observations play an important role in mathematics and the learning of the same. Polya (1945) described that:

“mathematics has two faces; it is the rigorous science of Euclid but it is also something else. Mathematics presented in the Euclidean way appears as a systematic, deductive science; but mathematics in the making appears as an experimental, inductive science. Both aspects are as old as the science of mathematics itself” (p. vii).

Experiments are part of the proving process in the sense that they help to identify structures and they give ideas how to proof theorems (Kortenkamp, 2014). A (young) subdomain of mathematics that uses (mainly) computer-supported experiments and simulations for this purpose is called experimental mathematics (Borwein et al., 2004). Besides the role experiments play in the proving process, mathematics and experiments meet each other in the experimental processes as it is performed in nature science, too. Quantitative experiments cannot be analyzed without mathematics – the data derived from an experiment undergoes a mathematical modeling process. Henning (2013) postulates that one of the most important functions of mathematics lies in supporting the understanding of our world.

The role of experiments in the mathematics classroom is closely connected to the relations between experiments and mathematics in scientific settings. In the existing literature we identified three learning situations related to experiments in mathematics:

- *Proving processes:* Regardless that proving is less present in school than in scientific mathematics, experimental work plays the same role in the proving process in school. Experiments can help to find a rule that could be proved and the ideas for the proof itself (Kortenkamp, 2014). “Experimental proofs” are part of the proving process of secondary students at school (Brunner, 2014).
- *Modeling:* Modeling is a key competence in mathematics lessons (Blum & Niss, 1991). But since modeling activities can be performed with “real” data derived from experiments as well as with data found in textbooks, the question arises whether the implementation of

experiments can enrich the modeling process. Following Carreira and Baioa (2018; 2011), experiments can enhance the credibility of modeling tasks and foster students' understanding of the real situation that is modeled and the involved mathematics. The use of "real" data from experiments can also enrich the validation of models and opens teachers' and students' view for the question what characterizes a good model and how one should act upon measurement errors which are inherent of experiments (Carrejo & Marshall, 2007).

- *Learning of new concepts:* Furthermore, experiments can support students' learning of new concepts. Ganter and Barzel (2012) showed that experiments can create a fruitful start for the learning of functional relations and, in particular, the manipulation of a variable during an experiment can help students to distinguish between dependent and independent variable.

Furthermore, experiments can increase students' interest in mathematics and their motivation (Beumann, 2016). As conclusion one might say that experiments can enrich mathematics lessons in various ways and learning situations. However, experiments are neither explicitly mentioned in the German mathematics curriculum, nor do they play a crucial role in teacher education. Thus, teachers' beliefs concerning experiments and the teachers' use of experiments in the classroom is widely unexplored. This contribution is a first step to investigate teachers' beliefs concerning experiments and their connection to mathematics.

## Beliefs and Experiments

Some recent studies addressed the beliefs of teachers in nature sciences concerning the role of experiments in the classroom and the goals obtained by using experiments. Science teachers' reasons to use experiments in their teaching practice include that experiments involve hands-on-activities, increase students' motivation and their conceptual and procedural understanding of nature sciences (Lavonen, 2012). In the special case of mathematics, teachers value the use of hands-on activities in classroom and believe that mathematics lessons should be student-centered (Wang & Cai, 2007) – experiments fall within both: hands-on activities and student-centered methods.

However, to the best of our knowledge there is currently no study (neither in science education nor mathematics education) focusing on teachers' beliefs concerning the nature of experiments and how experiments are connected to mathematics and mathematics learning. For a profitable use of experiments in class, teachers need to have appropriate beliefs about this method itself as well as about the relation to mathematics.

## Research Questions

Since on the one hand experiments can be beneficial for the learning of mathematics, and on the other hand teachers' beliefs affect their classroom practices (Grigutsch, 1996), we want to explore beliefs that teachers hold concerning experiments. This leads to the following questions:

- 1) Which beliefs are held by mathematics teachers concerning the notion experiment?
- 2) Which relations between experiments and mathematics do mathematics teachers see?

## Methods

Since the answers in liker-scale surveys are not easy to interpret when dealing with beliefs (Phillips, 2007) we decided to use open-ended questions within a paper and pencil questionnaire. The questions

where formulated as follows: 1) What do you understand under the notion “Experiment”? Give a brief explanation and typical characteristics. 2) In which way do experiments and mathematics fit together? Which relations between mathematics and experiments do you see?

The questionnaire was handed to 50 in-service teachers who worked at different types of schools in North Rhine Westphalia, Germany (primary school, lower and upper secondary schools). All of them were mathematics teacher and 24 taught another STEM-subject (like chemistry or physics) as well. All teachers participated voluntarily. We choose that variety of participants in order to gain a more global (yet not necessarily generalizable) picture of the teachers’ beliefs. However, not all teachers answered every question in the questionnaire.

The data analysis of this study is based on the “Grounded Theory” by Glaser and Strauss (1998). We constantly compared the data with each other by using open codes. Thus, we identified various beliefs concerning experiments. These beliefs have been discussed and grouped in categories. Given the limited space, we only give an overview of the main categories in this contribution.

## Results

Category	Description	Example	Quantity
<b><i>Procedure</i></b> ( <i>characteristics of the experimental process</i> )			
Experiments as planful and controlled procedure	Experiments are characterized by planful and controlled actions to verify a given hypothesis	“An experiment is an action, that is conducted under fixed circumstances [...] to check a hypothesis or generate one.”	17
Experiments as “trial and error”	Experiments are not planful or controlled. They do not need a hypothesis and are characterized by trying out and attempting different things.	“Try things out – involves that sometimes it goes wrong.”	22
Experiments as autonomous hands-on activity	Every kind of hands-on activity that provides autonomous working is viewed as experiment – regardless if it is planful or just trying.	“To solve a task with hands-on activities and practical solutions.”	10
<b><i>Aim</i></b> ( <i>aims connected to experiments</i> )			
Experiments aiming on (better) understanding	The aim of experiments is to (better) understand previously known things.	“Better understand relations.”	13
Experiments aiming at (new) knowledge	The aim of experiments is to provide new (at least from the viewpoint of the experimenting person) insights and knowledge.	“Experiments are a method to gain new insights.”	16

**Table 1: Beliefs concerning the nature of experiments**

Regarding the nature of experiments, we distinguish beliefs concerning the procedure of experimenting and the aims which are connected to experiments. Most teachers stated that they see experiments as either a controlled and planful action to check a given hypothesis or as uncontrolled trying without guiding hypothesis and plan. However, some teachers wrote that they see every hands-on activity as an experiment as far as it involves autonomous working. Besides these characteristics of the conduction of an experiment, most teachers stated that experiments aim at a certain goal: 16 teachers believe that experiments should lead to new insights and new knowledge – at least this knowledge should be subjectively new for the person that obtains the experiments. Other teachers focus more on the aim to better understand previously gained knowledge (Table 1).

Concerning the relation between mathematics and experiments we could identify two main beliefs (Table 2): 13 teachers stated that experiments are part of the process to generate new mathematical knowledge. Experiments are the inductive starting point of this process. 9 teachers see mathematics as part of the experimental process in other sciences – in this view mathematics is used to describe and model experiments. Two teachers stated no direct connection between mathematics and experiments but listed characteristics that both have in common. 3 teachers wrote that they see no relation between mathematics and experiments. However, despite the fact that we explicitly asked for a connection between experiments and mathematics, many teachers only wrote about the connection of experiments and classroom practices.

Category	Description	Example	Quantity
Experiments as a method in the mathematical process	Experiments are used in the mathematical process to generate new hypothesis that can be proven later.	“Mathematical statements are the result of a long process, obtained with the help of experiments”	13
Mathematics as toolbox in the experimental process	Mathematics is used to describe and evaluate experiments in other sciences and everyday life.	“Experiments and their results can usually be described with mathematics.”	9
Common characteristics of Mathematics and Experiments	Mathematics is not part of the experimental process or vice versa but both have common characteristics.	“Mathematics as well as experiments is based on plans to solve certain problems, the systematic conduction of the plan and the reflection upon the results.”	2

**Table 2: Beliefs concerning the relation between mathematics and experiments**

Like beliefs concerning the nature of mathematics, beliefs about experiments are not disjoint in the sense that teachers can either believe that experiments are planful and controlled or trial and error. The different beliefs can be held in various combinations. We illustrate this fact by describing the beliefs of three teachers more precisely:

Mr. A teaches mathematics and biology at an upper secondary school and wrote that he used experiments in his mathematics lessons before. For him a “clear mandatory setting and procedure” characterizes experiments. But he is aware of the fact that in every day life “experimenting” can be

viewed as less playful and less controlled: “Colloquial, experimenting can be aimless without mandatory setting and determined procedure.” He sees the connection between mathematics and experiments in modeling activities: “Insights from experiments can be mathematically modeled. The mathematical models themselves can be used for further predictions concerning the phenomenon. These predictions can be checked by new experiments. Mathematics and experiments can support each other in this sense.”

Mr. B teaches mathematics and physics at an upper secondary school and used experiments in his mathematics lessons before. For him, experiments follow a very clear and determined procedure: “Experiments consist of the observation of results, the investigation of dependences from single parameter, a defined procedure, and the reflection on the objects and used methods.” In contrast to Mr. A he sees no direct connection between mathematics and experiments but he stresses that the experimental process and the process of creating new mathematical knowledge have some characteristics in common: “Similar to experiments, an appropriate question and the development of ideas, hypothesis and conceptions belong to mathematics. On this basis theories can be developed and later be proven.”

Mrs. C works at an upper secondary school, too, but teaches no nature science and has not used experiments in her lessons so far. Mrs. C’s beliefs concerning the nature of experiments are less sophisticated. For her experimenting means to “try things out.” However, in her opinion experiments are an integral part of mathematical discoveries: “Mathematics is based on experimental work, like searching and finding schemas – that’s how discoveries are made!”

The exemplary comparison of Mr. A and Mr. B reveals, that the teachers’ beliefs concerning the nature of experiments as well as their background (both are teaching a second STEM-subject and used experiments in their lessons before) do not directly determine which connections to mathematics they see. Both teachers stress that experiments follow a defined procedure. However, Mr. A sees a clear connection between experiments and mathematics, while Mr. B does not see this connection. This result was observed amongst many teachers in our sample. Furthermore, we found no effect of STEM-teaching on the teachers’ beliefs concerning the nature or experiments.

## Discussion and Outlook

The teachers’ beliefs concerning the nature of experiments mainly reflect the discussion on a scientific definition of experiments (Borba & Villarreal, 2005) with the two (extreme) poles “experiments as trial and error” and “experiments as controlled procedure”. Given the fact, that modeling plays an important role in modern mathematics education, it is rather surprising that not more teachers saw this connection between mathematics and experiments. Especially since many teachers in our sample taught a nature science as well and, therefore, should be familiar with experiments. In our understanding, every analysis of a quantitative experiment in nature sciences needs mathematical modeling to some degree. However, 25% of the teachers reported that they see experiments as part of the process to gain new mathematical knowledge which is in line with Brunner’s (2014) model of proving processes in school. Furthermore, (computer-supported) mathematical experiments are of growing importance in scientific mathematics which should be reflected in mathematics education as well, according to Kortenkamp et al. (2014).

One limitation for our analysis is that we have no information about the teachers' beliefs concerning the nature of mathematics (mathematical worldview). These beliefs might affect which connections teachers see between experiments and mathematics.

With this pilot study we made a first step to understand teachers' beliefs concerning experiments in mathematics. Our ongoing research will now focus on two facets: 1) The reasons that lie behind teachers' beliefs concerning experiments (e.g. teachers' background and connections between teachers' beliefs concerning the nature of mathematics and their beliefs concerning experiments) and 2) the question whether (and how) mathematics teachers implement experiments in their mathematics lessons. In order to gain deeper insights into the connection of the teachers' beliefs and their use of experiments in mathematics lessons, semi-structured interviews as well as classroom observations will be used.

## **Chinese and Dutch mathematics teachers' beliefs about inquiry-based learning**

Luhuan Huang, Michiel Doorman and Wouter van Joolingen

Utrecht University, Freudenthal Institute for Science and Mathematics, Utrecht, The Netherlands;  
L.huang@uu.nl; m.doorman@uu.nl; W.R.vanJoolingen@uu.nl

*Teachers' beliefs are expected to have impact on the implementation of inquiry-based learning (IBL) in mathematics education. Moreover, Chinese and Dutch teaching cultures in mathematics seem to be very different. This paper presents results from semi-structured interviews with 30 Chinese and 19 Dutch mathematics teachers' beliefs about IBL. Statements were connected to main codes and ranked for each country. Dutch teachers focused on students' taking responsibility in IBL while Chinese teachers put extra emphasis on teacher guidance, they also talked about student discussion and collaboration. Chinese teachers paid attention to the benefits of IBL on mathematical thinking while Dutch teachers to the benefits on mastery and appliance of knowledge. In addition to the lack of time and suitable tasks as difficulties, Chinese teachers also mentioned students' lack of motivation and performance, while Dutch teachers mentioned the demands and openness of IBL.*

*Keywords: Mathematics education, inquiry-based learning, comparative study, teacher belief, lower-secondary education.*

### **Introduction**

As an intentional student-centered pedagogy rooted in the Western teaching culture, inquiry-based learning (IBL) encourages students to take responsibilities in the learning process, to explore by themselves, and to construct knowledge through actively participating in cycles like questioning, hypothesizing, designing, investigating, analyzing and reflecting (Swan, Pead, Doorman, & Mooldijk, 2013).

The understanding and implementing of IBL may be impacted by teaching cultures, while teaching culture of the East Asia is considered remarkably different from that of the West. These two teaching cultures have been identified and compared, which seemed to produce some stereotypes (Leung, 2001). From these stereotypes, the East Asia emphasizes learning content and related skills (Correa, Perry, Sims, Miller, & Fang, 2008; Leung, 2001) and values in-depth knowledge (Norton & Zhang, 2018), while the West emphasizes learning process (Leung, 2001) and values practical knowledge (Norton & Zhang, 2018); the East Asia conducts instruction to the whole class of students, while the West adopts individualized learning and group work (Leung, 2001); the East Asia considers teachers as the center and conducts well-organized directive instruction to deliver knowledge to students (Leung, 2001), while the West considers students as the center and encourages them to construct knowledge actively (Liu & Feng, 2015); the East Asia makes students learn by memorizing and practicing repetitively (Liu & Feng, 2015; Tan, 2015), while the West encourages meaningful learning (Leung, 2001); the East Asia motivates students by external factors such as examinations, while the West motivates students by internal factors such as interests (Leung, 2001).

These stereotypes about teaching cultures in the East Asia and the West also apply to the subject of mathematics. While the conceptualization of IBL in mathematics is less obvious (Artigue & Blomhøj, 2013). A large part of existing research focused on IBL in science, including research on science teachers' beliefs and practices of IBL (Wallace & Kang, 2004), a few of these research also included mathematics teachers (Marshall, Horton, Igo, & Switzer, 2009; Song & Looi, 2012). More attention needs to be paid to IBL specifically in mathematics.

As for the concept of IBL itself, no consensus has been reached about the definition, there exist a variety of interpretations about the IBL way of teaching approach (Furtak, Seidel, Iverson, & Briggs, 2012), especially about the amount of support provided to students, which makes IBL complicated to understand and implement for practitioners. Teachers may not have a complete understanding of IBL (Chin & Lin, 2013), and their beliefs about the detailed content of IBL tend to be diverse (Chan, 2010). In addition, IBL seems not yet a common practice embedded in daily teaching (Dobber, Zwart, Tanis, & Van Oers, 2017). Teachers' beliefs may shape their decisions and practice of implementing IBL (Saad & BouJaoude, 2012; Song & Looi, 2012; Wallace & Kang, 2004). While some studies also found a disconnect (Engeln, Euler, & Maass, 2013; Ramnarain & Hlatwayo, 2018) or a more complicated impact (Chan, 2010) between the beliefs and practice in regard to IBL. A deep understanding of teachers' beliefs towards the "complicated" IBL makes sense and may provide potential for better understanding their practice.

In an investigation into the beliefs and practices of IBL in mathematics, we explored from a students' perspective, and took China and the Netherlands as representing countries of the two teaching cultures (the east Asia and the West). The results showed that Chinese students reported more experience and preference of IBL than Dutch students, which challenge the stereotypes about the two teaching cultures. In this study, a teachers' perspective is to be explored.

The aim of this study is to present and compare Chinese and Dutch mathematics teachers' beliefs about IBL. The research questions are: What kinds of beliefs do lower-secondary mathematics teachers in China and the Netherlands have about inquiry-based learning (IBL)? What are the main similarities and differences on this issue between the two countries?

## **Methods**

### **Participants**

We interviewed 30 teachers from 15 Chinese schools and 19 teachers from 13 Dutch schools, all of them were teaching lower-secondary mathematics. 28 of the Chinese teachers and 9 of the Dutch teachers are female. The average age was 38 for Chinese teachers and 42 for Dutch teachers. As for the average years of teaching, it was 15 for Chinese teachers and 11 for Dutch teachers.

In China, generally a permission from school leaders makes it convenient to enter a school and conduct interviews, while teachers in the Netherlands have more freedom to accept an interview. Therefore in China we mainly contacted school leaders first, also a few local administrations, and some mathematics teachers directly, while in the Netherlands we invited individual teachers and included all teachers with interests. In both countries, participants were contacted mainly through an interpersonal network. Because of the large areas in China, we only collected data at Beijing, where

differences exist between urban and suburban schools, thus we ensured a balanced selection of eight urban schools and seven suburban schools to better represent the situation. In the Netherlands, schools at different areas are quite similar, we included different types of secondary schools<sup>1</sup>.

### **Instruments**

Data was collected through semi-structured interviews, which provided opportunities for teachers to express views and suit the research questions well. Without much presume about the definition or model of IBL, we left it open for teachers about their understanding of IBL.

We constructed an interview outline including general questions such as “what is your understanding of IBL” and two IBL example tasks as context to promote discussion. The tasks were chosen from materials of Primas project<sup>2</sup> and had potential for IBL, while they were not defined as IBL tasks in the interview, participants were asked questions such as “can it be used in an IBL lesson/do both versions represent IBL”.

The interview outline and example tasks were originally in English and translated into Chinese. The outline and tasks were piloted with two Dutch teachers and two Chinese teachers to make sure the questions and guidelines were clear enough and led to information we expected to collect. The pilot interviews also helped to prepare for practical issues that may happen during interviews.

### **Data collection and analysis**

Dutch participants were interviewed from April to June of 2017, and Chinese participants from October to November in the same year. Each participant was interviewed individually for around 40 minutes, the language was English for Dutch teachers and Chinese for Chinese teachers. The participant was asked if recording can be accepted. If not, the interview would not go on. Generally, questions from the interview outline were asked in sequence, and extensive questions related to the topic were also allowed. Similar introduction and guideline were given to each participant.

All the interview recordings were turned into transcripts. The original codes were constructed mainly based on the questions from the interview outline, “teachers’ responsibility” and “students’ responsibility” were derived from literature. All transcripts were imported into Nvivo 11 and divided into sets of fragments. Each fragment represents a single idea. In the process of coding - including individual coding and discussing differences – sub codes with example quotations were developed to create a better understanding of the main codes. The coding scheme (shown in Table 1) was adjusted for several rounds to be better connected to the transcripts<sup>3</sup>.

---

<sup>1</sup> In the Netherlands, students choose after primary school (grade 6) for one of three types of secondary education: pre-vocational secondary education (VMBO), senior general secondary education (HAVO) or pre university education (VWO) (source: <https://www.government.nl/topics/secondary-education>).

<sup>2</sup> The Primas project: Promoting inquiry-based learning (IBL) in mathematics and science education across Europe.

<sup>3</sup> For Chinese data, we analyzed and coded the original transcripts, then we translated statements and important quotations from Chinese into English.

When about half of the interviews had been coded, we introduced an external researcher to the interview outline and the coding scheme, and asked her to randomly choose one Chinese interview and one Dutch interview to code. The Chinese interview was coded together, and next the Dutch interview was coded by herself, resulting in a 69% agreement.

After coding, we arranged fragments with similar views together and extracted representative statements from those groups of fragments. For each statement, we counted how many teachers expressed this view during interviews. Based on the number, we ranked all the statements within each main code and kept the four highest-ranking statements to provide an overview of beliefs that the two groups of teachers have about IBL. If there existed multiple statements at the same ranking, all of them were kept or quitted. We counted and ranked for Chinese teachers and Dutch teachers respectively, then we compared the results between two countries.

## Results

As preliminary results of this study, Table 2 shows 30 Chinese teachers and 19 Dutch teachers' beliefs on three important aspects through the four highest ranking statements within each main code. For example, 12 of the 30 Chinese teachers talked about “students explore and find a way to the problem”.

**Table 2: High-ranking statements of Chinese and Dutch teachers on three aspects**

Main code	CN statements	n	NL statements	n
General Views	• <b>Students explore and find a way to the problem</b>	12	• <b>Students explore and find a way to the problem</b> by themselves	15
	• Students discuss and collaborate with peers	12	• Teachers do not provide explanations before students' exploration	5
	• Teachers guide the IBL process	8	• The problem can be solved in different ways	4
	• <b>Students think during the process</b>	8	• <b>Students think during the process</b>	4
	• Students come to the conclusion	8	• Students do activities to solve the problem	4
Reasons For	• <b>IBL develops mathematical thinking</b>	17	• <b>IBL leads to a better understanding, mastery and appliance of knowledge</b>	8
	• <b>IBL leads to a better understanding, mastery and appliance of knowledge</b>	14	• <b>IBL gives rise to more interests and motivates students</b>	7
	• <b>IBL gives rise to more interests and motivates students</b>	11	• <b>IBL is a way to develop general skills also necessary outside school and in future academic life and professional life</b>	6
	• <b>IBL is a way to develop general skills also necessary outside school and in future academic life and professional life</b>	4	• <b>IBL develops mathematical thinking</b>	4
			• To prepare for examinations	4
Difficulties	• Some students do not think or participate actively	11	• <b>Lack of time to prepare and do IBL sufficiently</b>	12
	• <b>Lack of time to prepare and do IBL sufficiently</b>	10	• IBL asks for a lot from teachers to design and implement it well	10
	• Students may not perform well in IBL tasks	9	• <b>Lack of suitable IBL tasks at hand</b>	8
	• <b>Lack of suitable IBL tasks at hand</b>	7	• Teachers don't want the unpredictable results and insecurity that IBL brings	6

Note: “CN” is the abbreviation of China, and “NL” of the Netherlands. “n” means the number of teachers who expressed this view during interviews. Content in bold were the shared statements for Chinese and Dutch teachers.

### Chinese teachers' beliefs about IBL

As is shown in Table 2, Chinese teachers talked about students' exploring, solving, thinking and getting the conclusion in IBL, they also connected IBL with student discussion and collaboration. In addition, emphasis was put on teacher guidance during the process. As for the reasons to implement IBL, Chinese teachers mainly focused on the benefits of IBL on mathematical thinking, knowledge and motivation, while only a few teachers paid attention to general skills developed from IBL. As for difficulties that teachers encountered in IBL, Chinese teachers pointed out factors related to students including the lack of motivation and performance in IBL, they also talked about factors related to conditions including lack of time and lack of suitable tasks.

### Dutch teachers' beliefs about IBL

As is shown in Table 2, Dutch teachers emphasized students' taking responsibility in IBL. They paid attention to students' exploring, solving, thinking and doing activities (such as drawing and calculating) in IBL, and they made it explicit that students explore by themselves without getting

explanations from teachers about the theory or problem-solving procedures. They also noticed that the problem used in IBL usually provided enough space for students to explore from different approaches. When it comes to the reasons for IBL, Dutch teachers talked about the benefits of IBL on knowledge, motivation, general skills and mathematical thinking, they considered IBL as preparation for examinations as well. As for the difficulties in IBL, Dutch teachers pointed out factors related to conditions including lack of time and lack of suitable tasks, they also included factors related to teachers, namely they were required a lot from IBL, and they expressed dislike about the uncertain and uncontrollable feature of IBL.

### **Comparisons between Chinese and Dutch teachers' beliefs about IBL**

As is shown by statements in bold in Table 2, Chinese and Dutch teachers shared some beliefs about IBL. Teachers in both countries paid attention to students' responsibility in IBL and mentioned students' exploring, solving and thinking. They both took the four benefits of IBL (on knowledge, mathematical thinking, motivations and general skills) as reasons to implement it. Moreover, they listed two common difficulties related to conditions, namely lack of time and lack of suitable tasks.

The differences between Chinese and Dutch teachers' beliefs about IBL are apparent in Table 2. As for the general views of IBL, Dutch teachers mainly emphasized students' responsibility in IBL while Chinese teachers also paid attention to teacher guidance (such as promoting students by questions) during the process. Chinese teachers talked about student discussion and collaboration and the attainment of results in IBL as well. The shared four benefits of IBL rank differently as reasons for IBL that Chinese teachers emphasized mathematics thinking most while Dutch teachers focused on knowledge most. Dutch teachers talked more about general skills, they also mentioned IBL as preparation for examinations. As for the difficulties in IBL, Chinese teachers listed factors related to students about their lack of motivation and performance in IBL, while Dutch teachers mentioned factors related to teachers that they considered IBL as demanding, uncertain and difficult to control.

### **Discussion**

Our findings are based on the samples from convenient sampling. Chinese data was only collected at Beijing with more advantaged educational resources, most Dutch teachers had connections with universities or research institutes, participants may be more active in exploring new teaching approaches. In addition, this study was limited to reported beliefs and lacked observations of actual lessons. Finally, although we tried to ensure a shared understanding of IBL by providing example tasks during interviews, the data might be biased if participants having different interpretations of a term like "inquiry" that originated from science education (Beumann & Geisler, 2019)

Despite the limitations of the study, some findings are in line with stereotypes about teaching cultures in the East Asia and the West. The attention of Chinese teachers on attainment of results, student performance, mastery and appliance of knowledge as well as teacher guidance in IBL match the stereotypes that the East Asia emphasizes learning content (Correa et al., 2008; Leung, 2001) and teachers' role in instruction. The attention of Dutch teachers on students' doing activities, general skills, students' taking responsibility before teacher explanation and student motivation match the stereotypes that the West emphasizes learning process (Leung, 2001) and practical knowledge

(Norton & Zhang, 2018), encourages students' constructing knowledge (Liu & Feng, 2015) and meaningful learning, and values students' internal motivations (Leung, 2001).

However, some findings are not in line with the stereotypes. The attention of Chinese teachers on students' exploring, solving and thinking, on student discussion and collaboration as well as on student motivation do not match the stereotypes that the East Asia conducts teacher-centered directive instruction to deliver knowledge (Leung, 2001), makes students learn by memorizing and practicing repetitively (Liu & Feng, 2015; Tan, 2015), conducts instruction to the whole class with little group work (Leung, 2001) and ignores students' internal motivations. The attention of Dutch teachers on knowledge and preparing students for examinations do not match the stereotypes that the West focuses on learning process more than learning content, and emphasizes students' internal motivations more than external motivations such as examinations (Leung, 2001).

Follow-up study will analyze other topics from the interviews such as IBL activities and IBL outcomes, we will also include the reported IBL practice of Chinese and Dutch teachers to see to what extent the reported practice match their beliefs about IBL, whether the beliefs shape the practice in regard to IBL or there exists a more complicated relation between them as suggested by literature.

### Acknowledgment

This work was supported by scholarship from the China Scholarship Council (CSC) [grant number 201606040155]. The authors thank Prof. Dongjiao Zhang, Dr. Xianglan Zhang as well as colleagues and friends that helped to contact teachers, and participants involved in this study for their contribution.

# Preservice teachers' mathematical knowledge for teaching combinatorial thinking

Veronika Hubeňáková<sup>1</sup> and Ingrid Semanišinová<sup>1</sup>

<sup>1</sup>Pavol Jozef Šafárik University, Faculty of Science, Košice, Slovakia;

[veronika.hubenakova@upjs.sk](mailto:veronika.hubenakova@upjs.sk) [ingrid.semanisinova@upjs.sk](mailto:ingrid.semanisinova@upjs.sk)

*In the paper, we conceptualize Mathematical Knowledge for Teaching as introduced and elaborated by Ball et al. (2008) for the topic of combinatorics using Lockwood (2013) model of combinatorial thinking. We developed test consisting of three combinatorial problems and 6 connected tasks (for each problem) focused on the Common Content Knowledge (CCK), Specialized Content Knowledge (SCK), Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT) to answer our research question: What are the differences in the combinatorial PCK between preservice teachers with regard to their combinatorial CK? We analyse and discuss data collected from 10 preservice teachers concerning one of the combinatorial problems and its connected tasks.*

*Keywords: Preservice teachers, combinatorics, pedagogical content knowledge, content knowledge.*

## Introduction and background

Combinatorial topics form an important part of the Slovak mathematics curriculum at middle and high school levels, as they are thought to provide a rich environment for the development of problem-solving skills (Rosenstein et al., 1997). However, Slovak curriculum documents and textbooks lead students to value formulas more than the ideas. Our aim in teaching preservice teachers (PSTs) is to broaden their knowledge to enable them to scaffold their future students' combinatorial thinking instead of the blind use of formulas. The motivation for our research is to inform our practice by both understanding more deeply how knowledge necessary to teach combinatorics is learnt and scaffolding such learning during the university studies of PSTs.

## Theoretical framework

In this chapter, we are going to frame topic-specific (combinatorial) preservice teacher mathematical knowledge. We build on the theoretical framework of Mathematical Knowledge for Teaching (MKT) as introduced and elaborated by Ball et al. (2008). More specifically, we focused on CCK, SCK, KCS and KCT. We use Lockwood (2013) model of combinatorial thinking to specify combinatorial MKT. We are going to explain the framework using the following combinatorial task (Batanero, 1997): Four children: Anna, Barbara, Cyril and Daniel went to spend the night at their grandparents' house. Their grandparents have two separate bedrooms for them (one downstairs and another upstairs). In how many different ways can the grandparents assign children to bedrooms? For example: Anna, Barbara, Cyril and Daniel will sleep in the room upstairs and nobody will sleep downstairs.

The task can be solved in at least six different ways as depicted at the Figure 1 (see the next page). We can see two different ways how to group them. In the first way, there are three groups: S1-S2, C1-C2, F1-F2. We can see different types of solutions here. The first group, there are *sets of outcomes* (S), collections of the objects being counted. In the second group, *counting process* (C) is clearly elaborated. In the third group, the solution stands on the using of the *formula* (F). The second way for

grouping the solutions is the following: S1-C1-F1 and S2-C2-F2. Each of the group of the solutions can be characterized by the same mathematical idea and they differ by the level of abstraction.

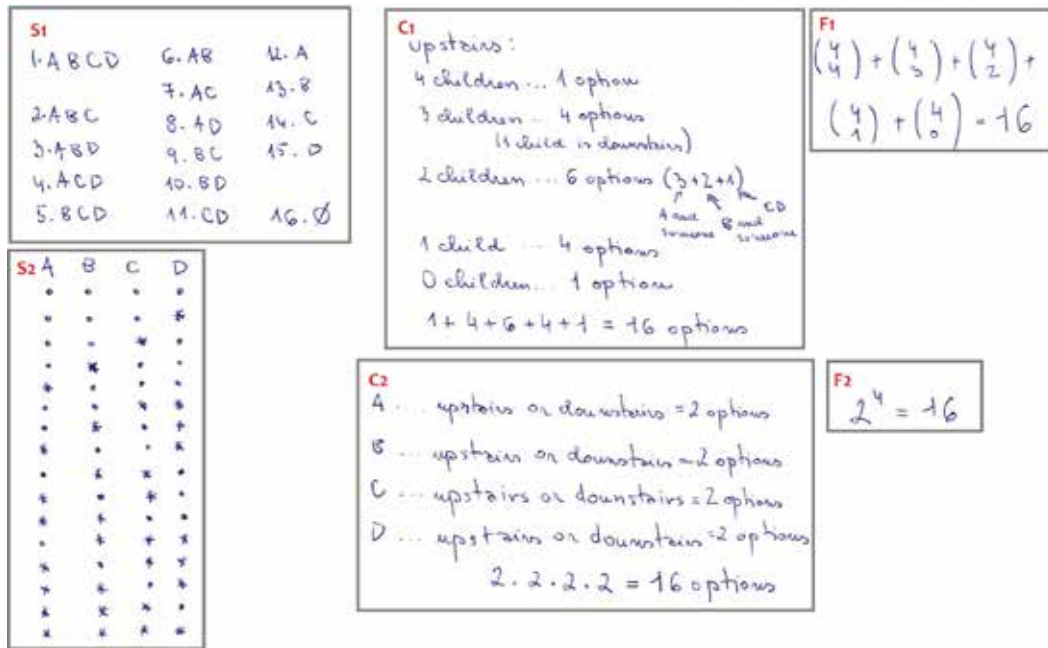

Figure 1: Six different solutions of the combinatorial problem

Lockwood model highlights the importance of developing the relationships between sets of outcomes, counting processes, and formulas/expressions. “For a given counting problem, a student may work with one or more of these components and may explicitly or implicitly coordinate them.” (Lockwood, 2013, p. 253).

Figure 2: Model of combinatorial thinking (adapted from Lockwood, 2013)

Now, we are ready to frame combinatorial MKT. **CCK:** PST can solve a combinatorial problem using one direction in Lockwood model, usually it is  $S \rightarrow C$  or  $C \rightarrow F$  and/or perceive some direction from the proposed correct solution, usually it is  $F \rightarrow C$  and/or  $C \rightarrow S$ . **SCK:** PST can solve a combinatorial problem in at least two different ways and perceives (not necessarily suggests) all directions of the Lockwood model. **KCS:** PST realizes that student solving the problem in the way S1-C1-F1 can have difficulties to understand the solutions S2-C2-F2 and perceives different levels of abstraction. Moreover, PST is familiar with possible student combinatorial misconceptions. **KCT:** PST's response to the student's solution is scaffolding in the sense of the Lockwood model, meaning that it shifts students to the proximal level of abstraction.

## Context and research question

The teacher education at bachelor's level (3 year program) at our university is, concerning MKT, currently focused on advanced mathematics knowledge, with SCK partially addressed. At the master's level (2 year program), the goals are framed mostly in terms of KCS and KCT development. This model is in line with the claim of Depaepe, Verschaffel and Kelchtermans (2013) from their literature review, which says: "Based on studies that use distinct test items to measure CK and PCK it is concluded that both knowledge components are positively correlated and that CK is a necessary, though not sufficient, condition for PCK." (Depaepe, Verschaffel, & Kelchtermans, 2013, p. 21) However, none of the papers these authors reviewed concerned combinatorics. What is more, the profound understanding of specific mathematical content is one of the possible points of focus for the research in teacher knowledge suggested at CERME 9 (Ribeiro et al., 2015). Therefore, we are interested, in accordance with the theoretical underpinnings and the needs of the field, to find the answer to the research question: What are the differences in the combinatorial PCK between PSTs with regard to their combinatorial CK?

## Research Methodology

### Participants

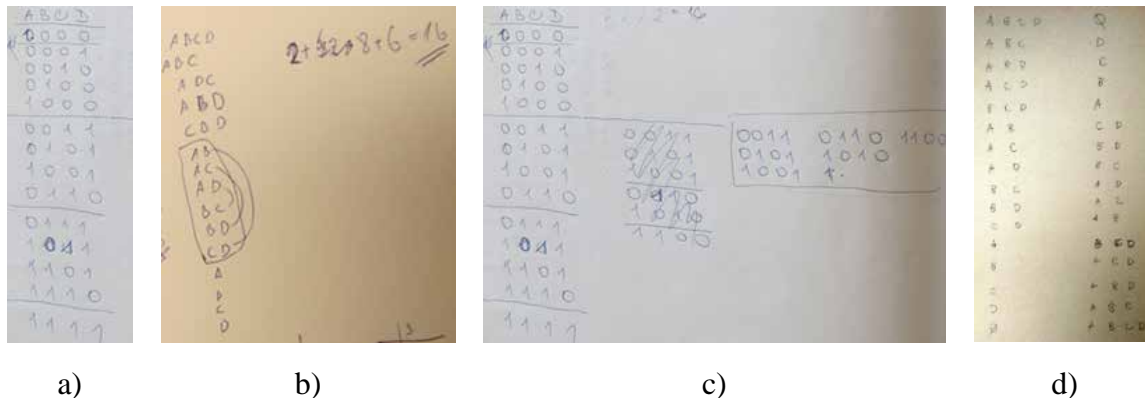

12 PSTs in the academic year 2017/2018 were finishing their master mathematics teaching programme, 10 of them participated in the data collection. They had already passed all mandatory courses, including *Discrete mathematics*, which aimed to develop advanced content knowledge concerning combinatorics, *Methods of mathematics problem solving* where among other things SCK was addressed and *Didactics of mathematics*. Therefore, we chose these participants to gain insight into our current practice of teacher education. However, their PCK could be developed outside of their mandatory courses. Thus, we needed to know whether the PSTs used other options to develop their PCK. Based on the short interviews, we found out that the university courses and mandatory school practices were more or less the only experience with mathematics education for 3 out of the 10 PSTs (*no additional experience*), 3 of them provided regular tutoring and/or lecturing (*narrow additional experience*), 4 out of the 10 PSTs, furthermore, have written diploma thesis in mathematics education (*broad additional experience*).

### Test design and its evaluation

We developed a research tool to capture PSTs' CK and PCK in domain of combinatorics in accordance with our theoretical perspective. As explained by Depaepe, Verschaffel and Kelchtermans (2013), if cognitive perspective to teacher knowledge is taken in account (what is the case here), then test is very relevant tool to measure it. The research tool consisted of three combinatorial problems with six connected tasks each. The first and the third connected task to the combinatorial problem measured the level of CK (Lockwood, 2013). The remaining connected tasks measured PSTs' level of PCK (Ball et al., 2008). All connected tasks were open-ended purposely, to let the PSTs display their CK and PCK without any restrictions or guidance.

All PSTs solved one standard combinatorial problem and one of two, randomly chosen, non-standard combinatorial problems. In the paper, we analyse 10 PSTs' solutions of the already introduced combinatorial problem (Batanero, 1997) and the following connected tasks (time allocated for the task is given in the brackets):

1. Solve the problem in several different ways (at least two). (8')
2. Which of your solutions is mathematically the most valuable? Explain why. (2')
3. There is solution  $2^4$  stated in the textbook. What set of outcomes corresponds with this solution? Write several elements of this set of outcomes. Explain. (5')
4. Imagine, this problem was solved by your students. Write down two examples of students' solutions containing mistakes which are expected by you. Explain them. (10')
5. Imagine, you are a high school teacher and you are solving this problem during the lesson. There are following students' solutions stated in their notebooks (in the Figure 3a and 3b). Explain these solutions and write down, how would you react. (5')
6. Look at the following students' solutions (see Figure 3b, 3c and 3d). Order them according to the level of abstraction (1 – the most abstract solution, 3 – the least abstract solution). Explain. (5')

**Figure 3: Examples of students' solutions for the connected tasks 5 and 6**

The test was firstly verified by 6 PhD students in mathematics (5 of them had already finished their mathematics teaching programme) in order to prescribe the sufficient time for each individual task, to refine formulations, and suggest the coding. Table 1 briefly summarizes the coding. The authors coded PSTs solutions separately, afterwards the coding was compared and few inconsistencies were discussed and resolved. According to CK (see Table 2), we categorized PSTs into three groups. The low CK group included the PSTs who demonstrated neither CCK nor SCK. The medium CK group included the PSTs who demonstrated only CCK. Finally, the high CK group included the PSTs who demonstrated both CCK and SCK.

PCK			
Task	Aim	What PCK components were coded?	
KCS	Task 4	Formulation of misconceptions	Is misconception typical and connected to combinatorics? Is explanation of the misconception focused on student's thinking?
	Task 6	Level of abstraction	Are solutions ordered according to level of abstraction? Are the reasons for ordering well explained?
KCT	Task 5	Response on student's solution	Does PST understand student's solution? Would the response which was suggested by PST scaffold student's learning?

**Table 1: Evaluation of PCK**

CK		
	CCK	SCK
<b>Conditions</b>	Problem solved correctly and/or understanding of the standard correct solution.	Problem solved at least in two different ways and correct mathematical argumentation.
<b>Combinatorial thinking</b>	One direction from Lockwood's model	All directions: $S \rightarrow C$ ; $C \rightarrow F$ ; $C \rightarrow S$ ; $F \rightarrow C$ ; $S \rightarrow F$ ; $F \rightarrow S$

Table 2: Evaluation of CK

## Findings & discussion

First, we describe the distribution of the participants into different categories. Table 3 illustrates that our research sample covered most of the possible categories. Only the category with low CK is not fully covered, however as the assigned combinatorial problem was standard, it is not surprising. Given the distribution into coded categories and subject numbers, we will analyse these data in qualitative and interpretative way.

Content Knowledge \ Additional Experience	None	Narrow	Broad
Low	1	0	0
Medium	1	2	1
High	1	1	3

Table 3: Numbers of PSTs grouped in categories

Second, we take a deeper look into each of the PCK components given in the Table 1. We will provide examples of PSTs responses to explain how they were coded.

### Formulation of possible student misconceptions<sup>1</sup>

#### Example A

Maybe they say: I choose who out of 4 children will be downstairs.  
and they write down (4) out of 4  
But they figure out it is equal 1 and thus it is nonsense.

#### Example B

Children will be in the rooms like this:

1 <sup>st</sup> room	2 <sup>nd</sup> room	
4 children	0 children	} 5 options
3 children	1 child	
2 children	2 children	
1 child	3 children	
0 children	4 children	

Figure 4: Examples of misconceptions

As we can see, in the Example A (Figure 4), PST tried to formulate misconception, however it is artificial and not connected to combinatorial idea. On the other hand, Example B (Figure 4) is very common one, it is called confusing the type of object (e.g. Batanero, 1997), it is clearly connected to combinatorics.

<sup>1</sup> We translated PSTs answers from Slovak language and re-wrote it to preserve the structure used by PSTs.

## Level of abstraction

### *Example C*

“Solution 3 (Figure 3d) seems the least abstract to me, because the student is writing down the set of outcomes from which it is clear what is happening in each of the rooms. It is obvious that he can imagine what is going on in there. Solution 2 (Figure 3c) is the most abstract because the student is grouping those people, however he probably does not really understand what he is doing.”

### *Example D*

“In the solution 3 (Figure 3d), there is clearly written which child is in which room ... students can immediately imagine – from the representation – how the children are split into two rooms. In the solution 1 (Figure 3b), there is some intermediate step from the specific solution to the abstract one, or an attempt to simplify, to shorten process of writing down the set of outcomes. The solution 2 (Figure 3c) – lot of children would be probably lost in such kind of solution. It is logical, however quite symbolic. Unlike the other two solutions, here are rooms assigned to children not children to rooms.”

In both examples, PSTs ordered the solutions in the correct way. The difference is, the PST from the Example C, did not notice different mathematical idea behind the solution 2 compared to solutions 1 and 3. On the other hand, PST from the Example D explains this difference.

## Response on student's solution (depicted in the Figure 2a)

### *Example E*

“I would call 4 volunteers, and I would ask the student with this solution to arrange them in all the possible ways when two of them are in the same room.”

### *Example F*

“I would probably give 50% for understanding and coding. I want the student to realize that the set of outcomes is not the most adequate solution.”

### *Example G*

“I would ask the student to check the set of outcomes whether it is complete. I would praise him for the representation of set of outcomes he came up with.”

Student's solution in the Figure 2a is the set of outcomes connected with the formula  $2^4$ . The activity suggested in the Example E is not related to this formula; therefore, it would probably not be scaffolding. In the Example F, PST would prompt student to use formula, which would not necessarily scaffold the student's combinatorial thinking if the student is not ready to see the relevance of formula to the situation. In the Example G, the PST recognized that she cannot orient the student to the counting process or formula without the student first comprehending how the set of outcomes is generated, thus it was coded as scaffolding response.

Third, we present which of the coded PCK components, were (+) or were not (-) observed in the particular categories of PSTs (see Table 4, the next page). In the Table 4, results of PSTs with medium and high CK are presented, the one PST with low CK demonstrated no PCK.

		None experience		Narrow experience		Broad experience	
		No SCK	SCK	No SCK	SCK	No SCK	SCK
KCS	Misconceptions	+	-	+	-	+	+
	Level of abstraction	-	-	-	+	-	+
KCT	Understanding	+	+	+	+	+	+
	Scaffolding response	-	-	-	-	-	+

**Table 4: PCK components demonstrated / missing in particular PSTs categories**

**Formulation of possible student misconceptions** as part of the KCS was missing only for PSTs with high CK without *broad additional experience*. These PSTs did not have an opportunity to learn from their own mistakes and the lack of experience was not supporting them to learn from mistakes of others. This could be the reason why they were not able to estimate what kind of misconceptions are common.

**Level of abstraction** as part of the KCS was observed only when PSTs had high CK and at least *narrow additional experience*. These differences can possibly be explained by the role of SCK as we defined it in combinatorics. If PSTs perceive all connections between possible solutions as suggested in the Lockwood's model, they are able to understand how abstract particular student's solution is.

**Understanding of the student's solutions** was managed by all PSTs except the one with the low CK. Obviously, the PST with low CK could not distinguish the nature of the error correctly, also she had troubles to reason the correct one. While the error was quite familiar, and the solution was the standard one, the other PSTs were able to explain the student's solution using only CCK, it was not necessary to activate SCK here.

Concerning **scaffolding response**, only the group of PSTs with high PCK and *broad additional experience* was able to provide scaffolding reactions. Moreover, the scaffolding reaction was suggested only if the level of abstraction was perceived and explained clearly.

## Conclusions

Let us return to the research question: What are the differences in the combinatorial PCK between PSTs with regard to their combinatorial CK? On the one hand, PSTs with low or medium CK displayed less PCK. On the other hand, when it comes to formulation of misconceptions, they outperformed those, who had high PCK and *none* or *narrow additional experience*. Thus, the high CK did not automatically meant good combinatorial PCK. It seems that the other necessary condition for combinatorial PCK development was *broad additional experience*. It supported PCK development especially when the PST had high level of CK. This is important, because PST who becomes a novice teacher is expected to learn mostly through their own teaching experience.

Back to our first motivation for the research, the findings will feed back to our research and practice in the following ways: (1) we need to inquire and specify how to develop combinatorial SCK effectively during the bachelor's level programme. (2) We need to identify the key factors of the *additional experience*, which scaffolded PSTs learning and subsequently design the PST education to promote these factors. Therefore, we need to focus on the task construction and design similarly to

PolICASTRO, Mellone, Ribeiro and Fiorentini (2019) and Montes, Climent, Carrillo and Contreras (2019).

Moreover, we will reframe the research with the model of Mathematics Teachers' Specialized Knowledge (Carrillo, et al., 2018) which address the limitations we experienced using MKT model (Ball, et al., 2008). We suggest that such reframing and the subsequent comparison could bring more clarity into mathematical teacher knowledge needed for teaching combinatorics.

*This paper examines how preservice primary teachers perceive mathematical horizon content knowledge for teaching in Malawi. Drawing on the practice-based theory of mathematical knowledge for teaching, the study highlights the importance of mathematical concepts and historical aspects needed for teaching, according to preservice primary teachers, at the beginning of their teaching education. Findings from the two cases revealed that despite differences in their perceptions, similarities also existed. This result provides a starting point for a better understanding of what composes mathematical horizon content knowledge and discusses implications for teacher-education training programs in Malawi.*

*Keywords: Malawian primary teacher education, mathematical horizon content knowledge, preservice teachers' perceptions.*

## Teacher's content knowledge for teaching

Becoming a professional at any workplace demands skills and knowledge to perform specific tasks, make decisions, and attend to what the profession requires. In this sense, becoming a teacher demands a specific type of knowledge that enables one to create sufficient conditions to trigger the students' learning (Davydov, 1999), develop their intellectual actions and mental functions (Vygotsky, 1987), and help them make sense of the world (Leontiev, 2007). In this context, why is this type of knowledge necessary to teach a subject properly? What difference does this knowledge have for the teaching of mathematics, and what are the implications for students learning in different contexts?

For decades, researchers around the world have investigated practices that can contribute to shaping teachers' knowledge. Shulman (1986), with his studies about teacher training in the USA, stands out in importance with his description of pedagogical content knowledge that extends beyond the specific topics of the curriculum. This type of knowledge represents a knowledge base that combines reflections on practical experiences and reflection on theoretical comprehension for teaching, a foundation that englobes the knowledge of the content, curriculum, students, contexts, and purposes/philosophies of teaching. Those elements, according to Shulman (1986), must be part of any educational program that forms primary and secondary teachers.

Of particular interest for mathematics teaching, Ball, Thames, and Phelps (2008) extended Shulman's (1986) ideas into two subcategories: *pedagogical content knowledge* (PCK) and *subject matter knowledge* (SMK). Whereas PCK includes the knowledge of content and students (KCS), knowledge of content and teaching (KCT), and the knowledge of content and curriculum (KCC), SMK comprises the common content knowledge (CCK), specialized content knowledge (SCK), and horizon content knowledge (HCK). Together, these six components offer a holistic perspective of what is useful and important for teaching. It also serves as a resource for addressing the mathematical demands of specific teaching tasks in primary classrooms (Hill, Rowan, & Ball, 2005) and a potential tool that

allows teachers to concentrate on what is essential for effective mathematics instruction (Ball et al., 2008).

Our focus is on teachers' mathematical knowledge beyond the school curriculum, HCK. Ball and Bass (2009) defined HCK as "a kind of mathematical 'peripheral vision' needed in teaching, a view of the larger mathematical landscape that teaching requires" (p. 1). It provides an awareness of "how the content being taught is situated in and connected to the broader disciplinary territory" (Jakobsen, Thames, Ribeiro, & Delaney, 2012, p. 4642) and "how mathematics topics are related over the span of mathematics included in the curriculum" (Ball et al., 2008, p. 403). Ball and Bass (2009) still explain that the knowledge at the mathematical horizon "is advanced knowledge that equips teachers with perspective for their work; it is not knowledge of the kind which they need to understand in order to explain it to students" (p. 27). Different from the other components in the teacher's MKT, the domain of HCK pays special attention to the processes involved in the creation and use of mathematical content rather than the content knowledge itself. It is a distinct knowledge that helps teachers engage and assist students to make sense of what is being taught from a global view of the subject matter.

In this article, we will focus on only one component of teachers' knowledge: HCK. Our aim is to provide a better understanding of how HCK is perceived in a different setting for teaching from which the theory was developed. To sustain this goal, we analyzed two cases taken from a larger research project that examines the preservice teachers in the context of Malawi. The main question addressed is: How do Malawian preservice primary teachers perceive the knowledge at the mathematical horizon at the beginning of their teacher education?

## **The study context**

The study presented here is drawn from a larger research examining the preservice teachers' sense-making process of mathematical knowledge for teaching in Malawi. Twenty-three students from a two-years teacher-training program volunteered to participate. In this program, the mathematics education aims to develop preservice teachers' critical awareness of mathematical concepts, and its connections and ways of being used for solving problems in a social, environmental, cultural, and economic context (Malawi Institute of Education, 2017). The mathematical program's curricular structure and syllabus allow future teachers to interim practice and theory by integrating content and pedagogy during their mathematical lessons at the college. In the first two of six terms of the program, preservice teachers should take theoretical courses (arithmetic and algebra subjects, accounting and business studies, measurement and data handling, and teaching and learning theories), followed by monitoring visits in local schools. The two middle terms are dedicated to teaching practices. They go onto the field in pairs to gain practical and professional experience in teaching under the supervision of practicing teachers. In the last two terms, the preservice teachers go back to college. The program is now committed to the reflection on preservice teaching experiences, inclusion and further discussion about teaching methods, subject contents, educational policies, and frameworks.

In the larger study, we adopted two approaches to generate data from the participants. The first approach was set up through preservice teacher notions on what types of knowledge and skills they thought could be most suitable for teaching mathematics in primary schools in Malawi. The main research instruments were a questionnaire including topics related to the participants' teaching

experiences and subject preferences, and individual interviews addressing the constituents needed for carrying out the work of teaching in Malawi. The interview structure was designed to cover most of teaching scenarios from which the six domains of mathematical knowledge for teaching theory could emerge (Ball et al., 2008). The second approach – only applied in a subsequent phase of the study – focused on observations of the preservice teachers' lessons. By selecting "teaching episodes" from which particular aspects of MKT domains manifest, we create reflection moments with the preservice teachers aimed to explore how they perceive the utility of those domains in practice.

Once more, in this paper we explore one aspect of teachers' knowledge: HCK. The following data stem from a case study (Stake, 2006) with two Malawian preservice primary teachers presenting distinctive ways to perceive HCK. The data collected was transcribed and condensed into a summary format. This format helped us establish analysis categories, with the MKT framework as a base. Those categories were expected to emerge from the preservice teachers' responses during the interviews, and the first pieces of evidence were projected to provide information on how the participants perceive HCK in the Malawian school settings. The idea was also to explore the basis and influences that shape the preservice teachers' perceptions before they went to the field work.

## **Preliminary Findings**

### **Intendence of placing contextual knowledge in teachers' HCK**

In this category, we analyzed the case of Patrick, a 20-year-old student possessing no teaching experience prior to entering the teacher training college. His parents are workers from the rural area and live in a village nearby the college. His favorite subjects in high school included biology, physics, and mathematics, while his interests lie in teaching mathematics and foundations studies.

During the interview, Patrick recognized the need to distinguish the knowledge and skills needed for teaching mathematics in primary school in Africa. This position, followed by the passage below, were pieces of evidence for understanding what Patrick might perceive as an HCK. The passage occurred during a discussion about the knowledge needed for teaching mathematics beyond the primary school curriculum.

Researcher: Ok Patrick, now... let's talk about the knowledge that a teacher needs to know beyond the curricular content.

Patrick: Sorry, I don't understand the question. Can you repeat, please?

Researcher: Yes... we talked about the importance for teachers to know the content, the curricular content in primary school, right? They also need to know the students, ok? But, is there anything else teachers need to know apart from those we have discussed? For example, numbers. If I decide to become a teacher in Malawi, what do I need to know to teach numbers? If I know the content, the students, and a couple of teaching techniques, is that enough?

Patrick: Hum... No! I think you should know more about Malawi... the Malawian context!

Research: Ah... Ok! You can say that! So, let's put it this way... In terms of mathematics teaching, you said a teacher needs to have good knowledge of the curricular

mathematics. But how about the mathematics outside of curriculum? [primary school curriculum]

Patrick: Yes, it is also important! Because there are other concepts that can explain some situations better. And also, you can apply those concepts to a situation. What is in the curriculum is good for planning, you know... but sometimes, the concepts in the curriculum are not enough. So, you can put them... you can mix them with those that are in the curriculum to explain something. So I think it's very important to do so.

Researcher: Can you give an example of that?

Patrick: In mathematics, for example... in Malawi we do farming. So, when you are teaching maybe some examples could be about farming, they [primary school teachers] should go further about agriculture, so the learners can reflect on what they do in their families as they do farming.

Researcher: So, is it important to give examples like this in class?

Patrick: Yes, when you are teaching, you have to give many examples. Those examples should be linked to real-life situations because it will be easy for them [students] to reflect on what they know, so they can understand and apply it [mathematics] in real life.

The forward reference shows that Patrick acknowledges not only the importance of curricular concepts in teaching but also the limits of teaching mathematics using only those concepts. He identifies that although the curriculum is essential for the teachers' planning activities, it might restrict the work of teaching from a general perspective. Patrick's perception of knowledge outside the school curriculum does not seem to corroborate with the suggested definition by Jakobsen et al. (2012), but it arises as part of a broader framework where mathematical knowledge takes place. Zazkis and Mamole (2011) explain that teachers' knowledge at the mathematical horizon also includes aspects in both the inner and outer horizons of an object. It encompasses the "connections between different disciplinary strands and contexts in which the object may exist" (p. 9). Students will only benefit from some of those features.

HCK as a contextual feature in teacher's knowledge is also a subject of interest for Zhang, Zhange, and Wang (2017). They pointed out that although HCK is directly connected to knowledge of a pure mathematical content, contextual factors can be adapted to the definition provided by Ball and Bass (2009), a type of knowledge that embraces

aspects of the mathematics that, while perhaps not contained in the curriculum, are nonetheless useful to pupils' present learning, that illuminate and confer a comprehensible sense of the larger significance of what may be only partially revealed in the mathematics of the moment (p. 6).

Therefore, in Patrick's case, we can see that this dimension manifests in the form of cultural values and explicit knowledge of the ways and tools needed in the discipline (Jakobsen et al., 2000), but it does not relate directly to the aspects of mathematical content contained in the curriculum. The example of the agricultural field provided by Patrick might not be transferred to mathematics, but it

represents the great world in which mathematics exists. *If a teacher wants to create in students the need for understanding and applying the concepts, he or she needs to think beyond the school curriculum*, explains Patrick.

Shoemaker (1989) explains that the acknowledgment of the relevance of contents hosted outside the traditional curriculum helps prospective teachers increase the opportunities for students to make meaningful associations with other areas of study, and develop new forms of abstractions of the real world. As a result, school subjects become more attractive, and students can appropriate concepts that are inherent to the world (D'Andrade, 1981). By doing so, teachers can facilitate students' learning by using concrete ideas and expanding them into abstract forms and new, concrete applications (Davydov, 1999).

### **HCK as an awareness of students' future needs and history of mathematics**

Our focus now is on Mario's case, a preservice teacher six years older than Patrick. Mario used to live with his family in a district in the central region of Malawi. His mother and father are retired, but both had worked as primary school teachers. After completing high school, he worked as an assistant teacher in a public primary school for three years. His favorite subjects were agriculture and social studies. At the teacher-training program, he still demonstrated a preference for teaching in those areas, including English and the local Malawian language, Chichewa.

In the interview, Mario presented two distinct ways to perceive the knowledge beyond the school content needed for teaching. He made emphasis not only to the importance of knowing the primary curricular contents but also to the knowledge needed to improve the quality of primary education by liking those to superior educational levels. The passage below occurred at our first interview with Mario, and it illustrates how he perceives the importance of having knowledge outside of the primary curriculum in Malawi.

- Researcher: Mario... what does a teacher need to know to teach in a primary school in Malawi? Does he need to know the content, right?
- Mario: Yes, because knowing the content you will be able to teach, and without the content, you don't know what to tell the learners.
- Research: But he needs to know just the contents of the curriculum?
- Mario: The content in the curriculum is important, but also you can extend it to the curriculum of secondary level. You can go higher! So you know what the upper classes is particularly doing about a particular topic is good because you can make a link to that. For example... in mathematics, we have geometry in upper level... we teach them how to find the angles or areas of triangles, so you if you don't have that knowledge you can not teach triangles in lower classes. So a primary teacher needs that knowledge!

By analyzing Mario's comments on what is needed for a teacher to know rather than what the curriculum suggests, we can see that he values the idea of establishing connections between the primary school curricular concepts and concepts from higher classes. In Mario's view, the benefits

of knowing mathematics from higher classes appear to be relevant because it facilitates the teacher's work in covering ideas that can be related to the current school mathematics content.

The suggestion that teachers' knowledge demands more than just knowing curricular contents is pertinent to understanding what Mario believe to be necessary for teaching mathematics in primary schools in Malawi. However, the idea of knowing how curricular mathematical topics are related to a more general curricular concept represents only a small portion of what constitutes HCK. Jakobsen et al. (2012) attempted to clarify that HCK implies not only the knowledge about curricular development of the contents but it also involves the knowledge about "how the content being taught is situated in and connected to the broader disciplinary territory" (p. 4642). It should go beyond the merely curricular progression where scholar concepts take place; in the case of the advanced mathematics, HCK emerges in understanding elementary mathematics from an advanced viewpoint, and vice versa (Klein, 2016).

The next passage is a sequence of the transcription above from which Mario expressed a second idea about the type of knowledge needed for a teacher to know rather than just curricular demands. The dialogue occurred when we asked him about what type of knowledge and skills are needed for planning a lesson activity in mathematics.

Researcher: When a teacher plans a lesson in Mathematics what things does he or she needs to know? I mean... beyond what the curriculum suggests?

Mario: As a teacher, you have to know why is there mathematics and who discovered the mathematics. Because when you are teaching learners, they have so many questions that if you don't know how to answer those questions you cannot help them. Some learners need to know why we need mathematics, who discovered this theory and these concepts? Who came up with this formula? And why? So he or she should be able to answer those questions. And for you to answer those questions, you should know the history behind the mathematics.

Researcher: So do you agree that it is important for primary school teachers to know the history of mathematics, I mean... the processes that led people to create the concepts?

Mario: Yes, I agree with that!

Researcher: But is it not too much for teachers? Generally, teachers give a task and some exercises.

Mario: No, it is not too much! This is part of the work. Because I want to take the learners from the very deep so they can easily understand what is about... so I want to take them from the very deep of what is really mathematics and all about mathematics. So they will be able to understand whatever the teacher is saying.

In the first part of the passage above, Mario argued in favor of the ability to think about the mathematical concepts critically. He suggested that knowing only the present form of concepts might not be enough for learners to have a complete conceptual understanding of what is being taught, so a teacher needs to be aware of the meaning and general principles that grip the existence of mathematics. Thus, the knowledge about the historical development that formed the concepts

reinforces teachers' conceptual understanding by giving insights into how the concepts were formulated and transmitted culturally (Shulman, 1982). Such awareness, consequently, permits them to establish associations and generalizations among other areas (D' Andrade, 1981).

Knowledge about the historical development of concepts is also important for one to perceive mathematics as a human production (Moretti, 2007). Studies by historical-cultural theorists have shown that the historical development of concepts occurred from concrete situations from which humans felt the need to solve them. Caraças (1984) explains that a number system, for instance, should not be seen as a pure product of human thinking because humans did not acquire the idea of numbers and then began to count. Natural numbers were formed slowly due to the daily practice of counting, rational numbers from measurements, real numbers from the logical compatibility of different acquisitions (Caraças, 1984). Being aware of the logical-historical aspects of mathematics, teachers have an opportunity to create conditions for students to establish systematic ways to understand the dialectical principles of concepts (Davydov, 1982). This type of knowledge, according to Jankvist, Mosvold, Fauskanger, and Jakobsen (2015), is one of the main characteristics that comprises the mathematical horizon knowledge of teachers.

## Conclusion

In the course of a larger research that investigates the preservice teachers' sense-making process of mathematical knowledge for teaching, the present article provided analyses on the perceptions of two participants regarding HCK. The findings revealed that both preservice teachers possess distinct ways of perceiving the knowledge outside of the curriculum and that those perceptions can contribute to a better understanding of what primary preservice teachers believe to be needed for knowing further than what the mathematical curriculum suggests.

These findings also have important implications for further research and teacher education practices. Knowledge about topics that might arise in learners' future studies is important for a teacher to possess, but it does not necessarily cover the idea of the advanced mathematical horizon proposed by the literature. HCK, in the sense of advanced mathematics horizon, encounters the understanding of concepts teachers want to teach in its totality considering its historical and cultural processes of production, representation, and validation (Shulman, 1986). In the context of teacher education, these results vindicate for teacher training programs provide even more insights, supports, and opportunities for reflections on the types of knowledge that anchor the broader disciplinary territory where mathematics takes place.

# Applying the Knowledge Quartet to student teachers' lesson plans: An intervention

Lena Karlsson

Linnaeus University, Sweden [Lena.Karlsson@lnu.se](mailto:Lena.Karlsson@lnu.se)

## The Knowledge Quartet

The Knowledge Quartet is a theoretical framework for analysing and developing mathematics teaching developed by Rowland, Turner, Thwaites, and Huckstep (2009) and elaborated on by Rowland (2014). The framework comprises four categories – Foundation, Transformation, Contingency, and Connection – that together constitute the mathematical knowledge needed by teachers. Within each of these four categories, several codes have been developed with which to identify and evaluate the knowledge of student teachers based on observations of classroom teaching. This poster presents and discusses an intervention addressing whether and how the Knowledge Quartet can also be used to evaluate the knowledge of student teachers based on their lesson plans. In teacher education, there are often few occasions to observe student teachers' teaching, which is why it is of interest to explore whether some of the knowledge to be revealed (or revealed to be missing) by using the Knowledge Quartet can also be revealed in reflections of lesson plans.

## The intervention

The intervention was conducted within a mathematics education course in lower primary school teacher education. In this course, the student teachers were to produce lesson plans for a series of lessons, implement one to two of these lessons, and then reflect on the series of lessons and on their implementation. The lesson implementation, however, was not observed by the teacher educators. The task was conducted in two groups of student teachers. In one group, the students were to write their reflections, and in the other group, the students were to record their reflections orally in video. For this poster, five reflections were randomly selected from each group.

In the written reflections, *Foundation* and *Connection* were the two dominant categories that were evident. In *Foundation*, a huge variety of codes was evident, the two most common ones being reflections on student beliefs (code A1) and reflections on the course (code A6). *Connection* was the second-largest category, and here the most common code was the student teacher's expectations about classroom complexity (code C1). In *Transformation*, the most common code was representations used in lessons (code B2). *Contingency* was only evident in one written reflection, in which one student teacher wrote about how she responded to and acted on her pupils' answers in the lesson (code D2).

In the oral reflections, *Foundation* and *Connection* were also the two dominant categories. In *Foundation*, several reflections addressed how assessment was to be carried out in the classroom (code A8), and another common code was the importance of using correct mathematical terminology and mathematical language even in lower primary school (code A7). *Connection* was the second largest category, and here the most common code was student teacher expectations about complexity in the classroom (code C1). The classroom setting was also common in the oral reflections code (code C6). In *Transformation*, the recordings of oral reflections featured how the student teachers chose examples and questions to be able to reveal student knowledge and understanding (code B1).

*Contingency* was the least common category in the oral reflections, though it was more common here than in the written reflections. The most common codes were how students could deviate from the lesson plan (code D3) as well as how the student teachers responded to their pupils' questions and answers (code D2). Even code D1, which deals with how the student teachers handle and act with pupils during instructions occurred.

### **New codes and sub-codes detected during analysis of the students' lesson plans**

In *Foundation*, a new code was added concerning students' thoughts about assessment. Among other things, the students reflected on complexity in assessment and teaching, and on the difficulty of finding the right teaching level and of fairly judging pupil knowledge. In *Connection*, two new sub-codes of code C1 (expectations of classroom complexity) were defined. One sub-code focused on pupils needing special support, in which the student teachers reflected on and discussed how to teach mathematics so as to include all pupils. This was obvious in both the written and oral reflections. The second sub-code connected to C1 was self-reflections on teaching, in which the student teachers reflected on the lesson structure and outcome, though this sub-code was only evident in the oral reflections. Another common sub-code, of code C6, in both the written and oral reflections was classroom framing. Socio-mathematical norms as well as ability grouping versus inclusion were important elements of this code; how pupils' language abilities influence their mathematics learning was also included as a sub-heading.

### **Reflection**

The Knowledge Quartet is a theoretical framework designed to be applied to observations of student teachers in the classroom. In this study the framework has been applied to two different forms of examination in a teacher program which generated new codes and sub codes not visible in the original framework. These codes and sub-codes might be specific to observe students' *reflections* on teaching. Through the new codes and sub-codes, it is visible that there is a tendency that the student teachers' reflections become clearer and broader examined through the film than through the text assignment. Hence, based on the intervention, I would argue that the refined framework of the Knowledge Quartet can be used to analyse students' reflections in lesson plans. However, the analysis of lesson plans differs from that of teaching as performed, as it indicates only whether the student teachers have the theoretical knowledge needed to teach a lesson, not whether they have the practical skills. Though, there are often few occasions to observe student teachers' teaching in teacher education, which is why it is of interest to explore knowledge to be revealed in reflections of lesson plans.

*The aim of this study was to investigate the effects of a faculty-school collaboration program on preservice mathematics teachers' professional knowledge and skills. Seven preservice teachers worked with a group of students from the collaboration school such that they attempted to understand and support students' mathematics through the implementation of mathematical tasks. Video tapes and written documents were used to detect any changes in preservice teachers' noticing of mathematical opportunities emerged from students' mathematics. A coding scheme was developed to understand the pattern in their noticing skills. The results revealed that preservice teachers were able to attend to mathematical opportunities during the implementations as well as in oral and written reflections took place after implementations. Furthermore, they began to enrich their interpretations of students' mathematics by giving examples from students' work and their interactions with students.*

*Keywords: Noticing, preservice teachers, mathematical opportunities, faculty-school collaboration.*

### Introduction

For effective teaching, teachers should support students' mathematical understanding by organizing appropriate learning environment for students and giving various learning opportunities for students as well as providing necessary scaffolding for their learning (Ball, Thames, & Phelps, 2008). Teachers' such ability of eliciting and interpreting students' mathematics and scaffolding their understanding is a sign of both their *Mathematical Knowledge for Teaching* (MKT) (Ball et al., 2008; Stockero, Rupnow, & Pascoe, 2017) and also their noticing skills (Jacobs, Lamp, & Philipp, 2010; Schoenfeld, 2011; van Zoest et al., 2017). Because MKT involves in knowledge of how students learn and understand mathematics while noticing entails attending to learning opportunities occurred during instruction, interpreting students' thinking and taking an action for fostering students' understanding (Jacobs et al., 2010). In other words, MKT and noticing skills of teachers are interrelated (Stockero et al, 2017; van Zoest et al., 2017). Indeed, in-service teachers have opportunity to improve such knowledge and skills in schools throughout years such that they could enrich their repertoire of students' thinking styles, capabilities and needs in mathematics as well as teaching strategies that are appropriate for their students. However, recent studies on preservice teachers' training (PSTs) revealed that intervention studies conducted under teacher education programs were likely to support development of PSTs' MKT and noticing skills to some extent as well (e.g., Barnhart & van Es, 2015). In the light of such findings, we developed a faculty-school collaboration program for PSTs to investigate the nature and the development of their professional knowledge and noticing skills. As a requirement of the program, PSTs worked with a group of students on the mathematical tasks in a school setting throughout a year such that they videotaped all implementation sessions and then reflected on the implementations both orally and in written.

### Theoretical framework

Noticing entails paying attention to important instances occurred in the classroom however it is difficult to decide what is noteworthy or not. In this study, we decided to focus on students'

mathematical thinking and understanding and we used Leatham and his colleagues' (Leatham, Peterson, Stockero & van Zoest, 2015) definition of *Mathematically Significant Pedagogical Opportunity to Build on Student Thinking* (MOST) as a unit of analysis to investigate PSTs' noticing skills. They described MOST as a composition of three sequential components such that it should be emerged from student's mathematical thinking, be mathematically significant and be a pedagogical opportunity (see for details Leatham et al., 2015). For instance, finding the answer of  $-8+5$  as  $-13$  might be counted as a MOST if it occurs while teaching operations with integers. In this case, the student thinks that addition of a negative and a positive integer is utilized as addition of natural numbers such that the sign of the first number is omitted first but then it is attached to the result. Because such an answer is observed while teaching integers, it is both mathematically significant and also a pedagogical opportunity to be discussed at that time in the class. Leatham and his colleagues also noted that not only students' misconceptions or incomplete reasoning but also their correct answers based on use of different strategies or approaches, mathematical contradictions or "why" questions might be coded as a MOST instance.

We adopted Jacobs and her colleagues' (Jacobs et al., 2010) definition of *professional noticing of students' thinking* to analyze PSTs' noticing skills. They defined noticing as having three interrelated components as attending to students' strategies, interpreting their understanding and deciding how to respond to students' mathematics. In this study, we analyzed PSTs' noticing in terms of whether or not they attended to MOST instance, how explicitly and accurately they interpreted students' thinking or student mathematics and how they responded to the MOST instance. We attempted to investigate PSTs' noticing during implementations (in-the-moment) and after implementations (in oral and written reflections). The implementation videos provided data about *attending* and *responding* while written and oral reflections used for *attending* and *interpreting* components of noticing. Although we asked PSTs to comment on their responding actions in oral and written reflections we did not count them as responding component but as a sign of interpretation of student mathematics as well as an indicator of their MKT.

## Methodology

### Research setting and participants

This study was conducted under a university-school collaboration program between a large university in Turkey and a local middle school in the neighborhood of the university. In the line of the collaboration, we took the responsibility of administration of an elective mathematics course offered for the seventh grade students in the school such that we grouped students and assigned a volunteer PST to work with these students on the mathematical tasks.

Seven preservice teachers attended to the program both in fall and spring semesters. Four of them were sophomore (Asya, Aydan, Ayla, Aysun) and three of them were junior (Bahar, Berna, Beste) undergraduate students of mathematics education program.

At the beginning of fall semester, a couple of weeks, we discussed about design and implementation of mathematical tasks as well as students' common misconceptions, and effective ways of understanding and supporting students' mathematical thinking. We discussed these issues via some sample videos and student work that we had in our repertoire from our earlier studies. Then we

assigned a group of four students for each PST that they would work with in the school for a year. Each group consisted of mixed ability students in terms of mathematics achievement.

We followed a 4-step intervention process for PSTs: pre-implementation discussion, task implementation, post-implementation discussion and written reflection. During pre-discussions we talked about the students' possible performance on the tasks as well as any modifications in the tasks before the implementation. Then, PSTs implemented the tasks in the school such that they allowed students worked on the tasks individually at first and then students discussed their answers as a group and finally PSTs began to interact with students to address mathematical opportunities occurred during the implementations. During post-discussions, each PST talked about how students performed on the tasks and how they addressed to students' mistakes or misconceptions. Each of these discussion sessions and implementations were videotaped. Then we asked PSTs to write reflection reports based on their videos and students' worksheets.

As the research team, we prepared 20 tasks such that 5 of them were about numbers, 7 of them were algebra, 5 of them were geometry and 3 of them were data and statistics. We also asked PSTs to prepare at least one task for each content area for their own groups and implement them. We used 2 lesson hours (80 min.) for each task implementation and we spent a total of 25 weeks in the school.

### Data collection and analysis

We used discussion and task implementation videos, and PSTs' written reflections as the main source for PSTs' noticing skills. Furthermore, we used task implementation videos and students' worksheets to identify MOST instances. We determined MOST instances according to Leatham and his colleagues' (2015) framework. Based on Jacobs and her colleagues' (2010) definition of noticing we developed a coding scheme to identify PSTs' noticing skills in terms of attending to MOST, interpreting student mathematics and responding to students. While developing the coding framework we used similar frameworks in the literature (e.g., van Es, 2011) and also made a workshop with math educators to get their suggestions. The scheme that we used for coding is presented in Table 1.

In the moment (Interaction)	Attending	0	Missed the MOST
		1	Attended to the MOST
	<b>Answer-focused</b>		
	Responding	0	(No attempt) Only tells to the students that their answers/solutions are wrong; no guidance for students
		1	(Explanation) S/he or other students tells/explains the procedure or solution
		2	(Orientation) Attempts to make students find out the correct answer through short-answer, Yes/No type, prompting (directs students to correct answer like "...isn't it?), no-follow up, non-specific type of questions or b) asking them to re-read, re-do, re-think
		<b>Mathematical understanding-focused</b>	
		3	(Exploration) Attempts to elicit students' thinking by asking probing questions (why, how, what if, ...) but either conversation is not concluded or in case of existence of misconceptions /misunderstandings she fails to address the gap in student's mind because her guidance involves partially incorrect issues such as lack of terminology, inappropriate examples or representations

Oral reflection		4	( <i>Elaboration</i> ) Attempts to elicit students' thinking by asking probing questions and guiding students through appropriate examples, representations, connections between concepts and representations
	Attending	0	Missed the MOST
		1	Attended to the MOST
	Interpreting	0	No interpretation
		1	Non-specific about student mathematics
		2	Specifically mentioned about student mathematics
Written reflection	Attending	0	Missed the MOST
		IR	Attended to the MOST both during Interaction and in Report
		I	Attended to the MOST only during Interaction
		R	Attended to the MOST in Report
	Interpreting	0	Does not provide any interpretation or states that she did not understand what the student did/thought about
		1	Just rephrases students' written procedures and/or points out students' mistakes
		2	Comments on the possible reasoning behind student mathematics but provides limited justification such as blaming student for lack of knowledge or her comments about student mathematics is partially correct
		3	Comments on the possible reasoning behind student mathematics by providing examples from students' work or vignettes from student-teacher interaction but do not explain the justifications explicitly
		4	Gives a detailed explanation about possible reasoning behind student mathematics by providing valid justifications

**Table 1: Framework for teachers' noticing skills**

We used different identifiers and levels for interpreting component of written and oral reflections because during oral reflections we gave a limited time for PSTs to talk however, they had enough time to write about implementation and students' performances. Furthermore, as the research team we discussed all MOST instances and codes for PSTs' noticing skills together. Thus, we have achieved a consistency in coding of each PSTs' noticing and MOST instances, in other words, we fully achieved interrater reliability.

## Findings

In this paper, we present the data collected from seven PSTs who attended to the program in both semesters. A total of 354 MOST instances (approximately two MOST instances per week for each PST) were detected throughout the year. Although Leatham et al. (2015) discussed various sources of MOST instances, including students' alternative solutions or their answers for "why" questions, in this study majority of MOSTs emerged from students' misconceptions. Furthermore, because we mentioned about students' possible misconceptions during pre-implementation discussions, PSTs were somewhat familiar to such instances before the implementations. Indeed, 45% of MOST instances were already mentioned in the pre-implementation discussions while 55% of them were new for the PSTs. The frequency distribution of how PSTs attended to those MOST instances is presented in Table 2.

Table 2: Coding of preservice teachers' noticing skills

When we analyzed data about noticing during implementations, we observed that the PSTs attended to majority of MOST instances in both fall and spring semesters (88% and 89%, respectively). In terms of responding to MOST instances, it was observed that PSTs attempted to guide students in some ways (totally 91% in Fall and 98% in Spring) but they mostly preferred answered-focused actions in both semesters (totally 88% for each semester). However, it was seen that in the spring semester they attempted to elicit students' mathematics in the form of *exploration* and *elaboration* more in comparison to fall semester (totally 3% in Fall, 11% in Spring).

In terms of written and oral reflections after implementations it was also observed that PSTs attended to MOST instances occurred during implementations. During post-implementation discussions the instructors from the research team asked about how implementation went and what PSTs observed about students' mathematical performances. When discussion videos were analyzed it was observed that PSTs mentioned about the MOST instances occurred during the implementations (68% in Fall and 81% in Spring). Furthermore, they attempted to give justifications for students' performances such that the percentage of such specific comments about students' mathematics increased in spring semester (50% in Fall, 69% in Spring).

The PSTs attended to some of the MOST instances that they missed during the implementations in their written reports such that in total they attend to 10 of the 18 missed MOSTs in fall (approx. 56%) and 13 of the 21 missed MOSTs in spring (approx. 62%). However, there were cases that PSTs did not write about the MOST instances even though they attended to them during the interactions. When we compared the semesters, the number of such cases decreased in spring semester from 17% to 9% as seen in Table 2. That is, PSTs attended to MOST instances in both during interaction with students and in their written reports (71% in Fall and 80% in Spring). We also analyzed how PSTs interpreted student mathematics in their written reports. It was observed that all PSTs attempted to interpret students' mathematical thinking behind the MOST instances. Although in fall semester the percentage of the cases that PSTs only wrote about what students did (Level 1 in coding scheme) was high, it decreased in the spring semester (43% in Fall, 25% in Spring). That is, they began to comment on students' mathematics by providing justifications from their interactions with students and students' written work (totally 56% in Fall and 75% in Spring).

We also analyzed how each PST's noticing varied in fall and spring semesters. As shown in Table 3, we analyzed their responding actions during interactions in terms of answer-focused vs mathematical-understanding focused. We also categorized their interpretation of students' mathematics in terms of providing justifications or not. As seen Table 3, Aydan showed a progress in terms of attending to MOST instances in the moment of implementations. In terms of responding actions, except Aysun, PSTs attempted to elicit or elaborate students' mathematical understanding during the interactions such that there were more instances coded as "3" or "4" in spring semester. The PSTs also attended to MOST instances and specifically mentioned about students' mathematics during oral reflections. This fact was more evident in Asya's, Aydan's and Ayla's cases as shown in Table 3. Although all PSTs attempted to provide justifications for their interpretations of students' thinking in their reports, the change in Aysun's and Bahar's written reflections during spring semester was noteworthy. For instance, in fall semester Bahar was just writing about what students did or she blamed students having lack of knowledge however in spring semester she began to explain the reasoning behind

students' mathematics by providing examples from student work or sample vignettes of group discussions.

**Table 3: Variations in preservice teachers' noticing skills**

## Discussion

In this study, we attempted to create an opportunity for PSTs to investigate nature and development of their in-the-moment noticing skills as well as noticing based on analysis of their own videos. As aligned with the findings of intervention studies mentioned in the literature (Barnhart & van Es, 2015; Stockero et al., 2017) this faculty-school collaboration contributed to PSTs' noticing. Firstly, PSTs were able to attend majority of MOST instances occurred during implementations. Pre and post implementation discussions might help PSTs to recognize the MOST instances because we talked about students' possible misconceptions and difficulties as well as how to eliminate such misconceptions during the discussions. Furthermore, as they got to know their students they got better in predicting their students' performances so that they had prepared for MOST instances which were likely to occur during implementations. This fact could be thought as an improvement in their MKT specifically in their specialized content knowledge and knowledge of students and content. Secondly, we observed changes in PSTs' responding actions throughout the year such that almost all PSTs achieved a transition from "No attempt" to "Elaboration" type of responding. However, such transition was not in progressive fashion (Barnhart & van Es, 2015) most probably because variations in students' prior knowledge and the context of the tasks (Kilic, Dogan, Tun, & Arabaci, 2018). For further studies, PSTs might be trained more for eliciting and elaborating type of responding actions before implementations of the tasks with students. Thirdly, analysis of own videos supported PSTs' noticing skills (Barnhart & van Es, 2015; Stockero et al., 2017) such that they were able to recognize

and wrote about the MOST instances that they missed during interactions in their reflections. Furthermore, written reflections provided an evidence for how PSTs interpreted students' thinking which was implicit in implementation videos.

Briefly, in addition to their theoretical courses, teacher educators should provide hands-on experiences for PSTs to promote their professional knowledge and skills. Although analysis of own teaching videos contributed to PSTs' noticing skills, for in-the-moment noticing, they should be given opportunities to work with students or teach in a classroom for a long period of time.

*Research on teacher knowledge and beliefs in mathematics has a long history (Philipp, 2007). However, research on teacher knowledge and beliefs with respect to process-related thinking is relatively new. Even though studies have been conducted in this area, especially regarding proof and proving, most did not focus on primary grade teachers' knowledge and beliefs. Moreover, when researching mathematical knowledge and beliefs on process-related mathematical thinking, an adequate methodological tool is still an issue of concern. The goals of this paper are twofold: (1) to present an alternative approach to capture mathematics teacher conceptions on the basis of Kelly's (1955) theory of personal constructs, and (2) to discuss a design of a repertory grid to research primary grade teacher conceptions of argumentation. In the end, we discuss the potential of repertory grids as a tool to grasp teacher conceptions on process-related thinking in general.*

*Keywords: Teacher conceptions, process-related mathematical thinking, semi-structured interviews, repertory grid, elementary school teachers.*

## Introduction

Process-related competences, such as argumentation and problem solving are essential for learning mathematics. When introducing habits of mind in an educational context, Cuoco, Goldenberg, and Mark (1996) highlight amongst others these activities for mathematics classroom. They argue that in school mathematics specific results are of little importance in contrast to habits of mind as used by mathematicians and that teachers should help students to “learn and adopt some of the ways that mathematicians think about problems” (Cuoco et al., 1996, p. 376). As teachers play a vital part in enabling this type of learning, it is necessary to understand their practices. Consequently, examining teacher knowledge, beliefs, and identity is a relevant research focus. Similarly, at CERME9, the TWG20 on teacher knowledge, beliefs and identity underpinned this claim. Moreover, as a group they considered these areas “as the core of a teacher's practices, with each area influencing and being influenced by others” (Ribeiro, Aslan-Tutak, Charalambous, & Meinke, 2015, p. 3178).

As outlined in Philipp (2007), plethora of research in the area of affective domain has been conducted, where the focus primarily lied on mathematics as a subject or on specific content areas. When focusing on process-related mathematical thinking, teacher beliefs about proof and proving are dominant research areas, but merely consider secondary and tertiary education (e.g., Conner, Edenfield, Gleason, & Ersoz, 2011). Investigating more specifically teachers' actions, the case analysis by Ayalon and Even (2016) showed how teachers' understanding of mathematical argumentation influenced their way of teaching, pointing out how opportunities of engaging students in argumentative activities are made available, and shaped by the teacher. In primary education, researchers have shown that teachers play an important part in initiating argumentative processes and

determine how students participate in these processes in class (e.g., Forman, Larreamendy-Joerns, Stein, & Brown, 1998). Thus, it is vital to understand teacher conceptions of argumentation, as discussed as well by Ayalon and Naama in this TWG20 at CERME11. Extending the research from secondary to primary education seems appropriate and beneficial.

In this direction, we conducted an exploratory case study guided by the question what conceptions primary grade teachers hold specifically with respect to mathematical argumentation (Klöpping & Kuzle, 2018). For that purpose, we developed a guideline for a semi-structured interview. Although the exploratory study already yielded some noteworthy results, such as that mathematical argumentation was seen by the teachers as processes of understanding or as a tool for critical analysis of results, the instrument needs to be revised in order to facilitate the comparison between teachers, and to make it feasible for larger samples. Furthermore, the connection between the teachers' conceptions and their classroom practice should be emphasized in order to understand this multi-faceted phenomenon better.

On the foundation of our case study (Klöpping & Kuzle, 2018), we present an alternative methodological approach for exploring teacher conceptions of process-related mathematical thinking, and discuss this approach in the following. The article contributes to the demand to highlight the connection between “aspects of mathematics teaching and learning” and “teachers' intertwined knowledge” (Ribeiro et al., 2017, p. 3221).

### **A few remarks on researching teacher knowledge and beliefs**

In 1992, Thompson coined the term conception as “a general notion or mental structure encompassing beliefs, meanings, concepts, propositions, rules, mental images, and preferences” (Philipp, 2007, p. 259). The distinction between knowledge and beliefs is not made very clear, therefore, the term conceptions arose which acknowledges the important relationship between these two mental structures and combines both notions (Philipp, 2007). Researching these mental structures, especially beliefs, Philipp (2007) found generally two methodological approaches to be present: studies following a case analysis approach and research using assessment instruments. The latter includes surveys using Likert-type scale to measure mathematical beliefs and testing theory, whereas the former approach used for building theory is more common (Philipp, 2007). Both approaches use a wide variety of research instruments exploring “beliefs about students' mathematical thinking, about curriculum, and about technology” as the “three major areas” (Philipp, 2007, p. 281).

Research on teacher beliefs about process-related mathematical thinking started in the domain of proof and proving (e.g., Conner et al., 2011; Knuth, 2002). When referring to other process-related competences, research on teacher knowledge and beliefs can be found within the teaching of conjecturing and argumentation (e.g., Bergqvist, 2005; Katsh-Singer, McNeill & Loper, 2016). Following this line of research, we explored teacher conceptions (knowledge and beliefs) regarding mathematical argumentation in German primary education using semi-structured interviews (Klöpping & Kuzle, 2018). Questions within the interview guide concerned either argumentation in the field of mathematics (e.g., What purpose does argumentation serve in mathematics?) or argumentation in the context of teaching (e.g., How do you envision the role of argumentation in your classroom? How important is it for you?). However, we found comparing the teachers' conceptions

and connecting these conceptions with their classroom practice as unnecessarily difficult, leading to a search for alternative research methods.

### **An alternative approach to mathematics teacher conceptions research**

In 1955, Kelly introduced the term *personal constructs* and thought of them as a way for individuals to describe their personality and their surroundings in terms of how some subjects, objects or situations equal one another and are yet different from other things. The constructs are labeled as “personal” because they vary from person to person. This mirrors Kelly’s interest in individual aspects of self-concepts and the social perception of individuals (Westmeyer, Weber, & Asendorpf, 2014). On the foundation of this psychological cognitive theory, Kelly (1955) derived an instrument – the so-called *role construct repertory test* (or shorter repertory grid) – that can give insight into personal constructs which indicate how individuals think, act, and feel. This approach can be seen as a methodology for mapping cognitive structures, which includes shared and unique elements of persons’ cognitive systems (Kelly, 1955; Tan & Hunter, 2002).

In praxis, a repertory grid is a technique employed within an interview. On the basis of the interview’s topic, *elements* are selected first. This selection is an essential part of a grid as it defines the underlying material. Grounded on Kelly’s theory of personal constructs, the nature of these elements always permits that a pair of elements can either be differentiated or be seen as equal when examined through personal *constructs*. A repertory grid finally establishes a *link* between all elements and the personal constructs which came up during the interview. Applying it as an instrument for research in mathematics education demands careful deliberation of these components.

*Elements* in a repertory grid should belong to the same category to ensure that elicited or given constructs are applicable to all elements. This call for homogeneity does not mean that there should not be distinctive or contrasting pairs of elements. Quite the opposite, it should be thought of a representative coverage including contrasts to allow for a wide range of constructs (Easterby-Smith, 1980). Additionally, Easterby-Smith (1980) implies that all interviewees should be “able to relate directly to the elements specified” (p. 4).

*Constructs* are utilized to attribute characteristics to elements helping to distinguish between them and reveal how the elements differ according to the subjects understanding. Eliciting constructs from triads of elements is, according to Easterby-Smith (1980), the classical approach of generating constructs where the subject has to state “in what way two of the elements [in a triad] are alike and in what way the third element is different from the other two” (p. 6). In this process, a construct with two opposing poles is produced followed by a new selection of elements for the next triad.

As far as the *linking mechanism* is concerned two general options are on hand: rating or ranking elements. Ranking forces the participants to differ between elements regarding a certain construct even if they see no difference. This is why rating scales are common and most often used varying from dichotomous scoring to five, seven or even more point scales (Tan & Hunter, 2002). Nowadays, technology allows for more subtle grading why a visual analog scale could as well be a viable option, but it has, to our knowledge, never been used in a repertory grid.

Philipp (2007) points out that cognitive structures, such as knowledge, beliefs and attitudes are intertwined. Since a repertory grid does not explore these areas separately, but in a more holistic manner, we see great potential to the field of knowledge and beliefs research. Upon this methodological consideration, a design of a repertory grid in the context of process-related mathematical thinking exemplified through argumentation will be elaborated in the following section.

## **Design of a repertory grid on conceptions of argumentation**

As noted earlier, in our exploratory case study with three German primary grade teachers we employed a guideline for a semi-structured interview as a data collection tool (Klöpping & Kuzle, 2018). Taking into consideration the discussed perspective on researching mathematics teacher conceptions, re-thinking the nature of the interview guide may be beneficial. To explore in this way teacher knowledge and beliefs from a different angle, a repertory grid will be integrated in the existing guideline. The integration of Kelly's ideas should be rather thought of as a methodological synergy than a rejection of established approaches.

Within the conducted exploratory case study, the interviewees were asked to evaluate fictional student explanations. We identified this section as a promising part to integrate a repertory grid. First, the participants were shown the following mathematical statement: For any positive integers  $a$  and  $b$ , if  $a + b$  is an odd number, then one of  $a$  or  $b$  is an odd number and the other is an even number. Then, fictional student arguments which underpin the mathematical statement were presented asking the participants to discuss these by referring to the following guiding questions:

- What do you think of this argument?
- Would you expect this argument from an elementary school student?
- Do you think this argument would convince elementary school students? Why or why not?

The teachers' answers show significant shreds of evidence to explain what their beliefs on mathematical argumentation, their knowledge, and their expectations for classroom interaction and implementation of argumentation are. Herein, distinct functions of argumentative structures in the classroom were emphasized by the teachers. In the interviews, mathematical argumentation was seen as processes of understanding, as practical knowledge, as a tool for critical analysis of results, and as supportive for self-reflection among other (Klöpping & Kuzle, 2018). Nevertheless, the approach missed the opportunity to link and relate the teachers' perspectives on the fictional student explanations to one another. Difficulties arose as well when the teachers' evaluations of the student explanations were compared among each other. At this exact point, we see potential in the application of a repertory grid to better understand teacher conceptions of argumentation.

The evaluative section on fictional students' arguments can be changed into the format of a repertory grid. First, the teachers are shown the mentioned mathematical statement on parity and develop their own argument, which will be used as one element. Then they are asked to discuss the students' arguments applying the method of a repertory grid. Table 1 shows exemplified components of such a grid where the fictional student explanations from the former guideline still exist, but are now supplied as elements instead. Evaluation and discussion of all arguments within a repertory grid needs Kelly's personal constructs. Each construct (see Table 1 on the left) has a counterpart: a contrast (on the right). For example, a teacher could describe an argument as "mathematically correct" whereas

on the opposite side of the same scale other arguments can be seen by that teacher as “improper”. The exemplified linking mechanism includes a dichotomous scoring and a five-point rating scale.

		Elements					
		Ana's Argument	Benjamin's Argument	Clara's Argument	...	Teacher's Argument	
dichotomous score	Constructs						Contrasts
	mathematically correct (✓)	–	–	✓	...	✓	improper (–)
	comprehensible (✓)	✓	–	✓	...	✓	abstract (–)
	helps to understand the statement (5)	1	3	5	...	4	confusing (1)
	adequate for primary (5)	3	5	4	...	5	higher mathematics (1)
	...						...
five-point rating scale							

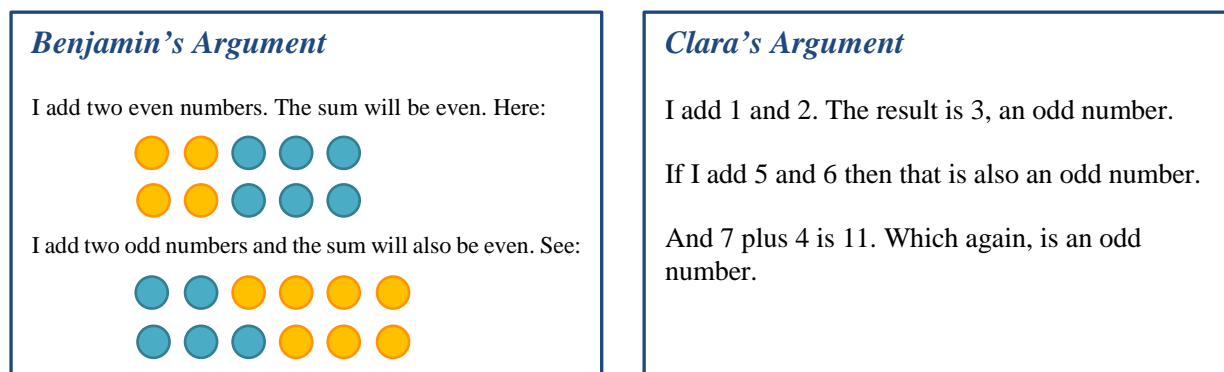

**Table 1: Example layout of a repertory grid on argumentation with different linking mechanisms**

As elements relate directly to the topic of the interview, they should be the starting point when thinking about the design of a grid. Easterby-Smith (1980) recommends to use a small grid with clearly specified elements. Selecting elements can be done by supplying them, by providing descriptions of roles or situations, or by discussing the research topic with the subject and choosing elements jointly (Easterby-Smith, 1980). In our suggestion above, elements will mainly be supplied as all fictional students' arguments are determined in advance. This supplement of elements is adequate as it securely allows for interpersonal comparison, which requires the elements in all grids to be equal or at least to be equivalent.

Given that the elements are to be fictional students' arguments and that all elements together should reach representative coverage, a theoretical foundation for the supplied elements is needed. Balacheff (1988) introduced a taxonomy of proofs and proving, namely naive empiricism, crucial experiment, generic example and thought experiment. Further elaboration of this theory showed that it helps as well to distinguish types of arguments (Reid & Knipping, 2010). For the elements in a repertory grid on conceptions of argumentation these categories can be used and we suggest that each one is covered at least by one element to ensure that they incorporate all important types of arguments.

We present two fictional student explanations to give an idea of the anticipated grid's elements (see Figure 1). Benjamin's argument is a *generic example* (Balacheff, 1988) in which the generality of the statement can easily be seen. On the other hand, Clara's argument shows a *naive empiricism* (Balacheff, 1988) with loosely connected examples. To this pool of supplied elements (in our case arguments) the teacher's own argument in favor of that statement is added as another element. Such

procedure may allow for a more explicit connection between knowledge and beliefs of the interviewed teacher. Within a repertory grid, the following evaluation of these arguments is done with the help of personal constructs.

**Figure 1: Examples of elements in a repertory grid on argumentation**

While supplying constructs is a quick and easy way to begin linking them to elements, respectively to evaluate the arguments through them, it is difficult to assure that the supplied constructs mirror the conceptions of all interviewees and, furthermore, to assume that the subjects have “an adequate understanding of what [the constructs] mean” (Easterby-Smith, 1980, p. 6) seems delicate. The exemplified construct “mathematically correct” in Table 1 can be understood very differently. One teacher might think of it as the opposite of improper or false whereas another teacher judges the arguments correctness by its rigor. As teacher conceptions of mathematical argumentation in primary education have not been sufficiently studied, supplying constructs might end in misleading interpretations, and results. Hence, it seems more adequate to generate them from triads of elements, as it is the classical approach in a repertory grid.

However, making use of the methodological synergy, an alternative could be to as well emerge some constructs during the open question part of the interview. In our exploratory case study (Klöpping & Kuzle, 2018), the question “What makes an argument convincing?” lead to a possible construct as shown in Table 1. One teacher stated that if an argument is comprehensible then it is also convincing. Using this statement as a construct in a repertory grid, the contrasting pole must be clear. In this case, the teacher meant it as the opposite of “abstract”. With this understanding all arguments, respectively elements, can be rated on a scale from “comprehensible” to “abstract”. This way of evaluating and interpreting persons, objects, or situations is the core idea of the repertory grid (Kelly, 1955). Moreover, this highlights how open questions from a semi-structured interview can contribute to a repertory grid. In return, the linking mechanism of the grid addresses quantitative evaluations.

Following established research methods, we suggest to use a five-point rating scale as the linking mechanism, because this lays the basis for a comparison with research using a five-point Likert-type scale. Dichotomous scoring, on the other hand, can decide whether an element fulfills a characteristic or not, which might be helpful in some cases. The adequate linking mechanism depends strongly on the constructs, which signifies that no general decision can be made.

## Conclusion and final thoughts

Following an alternative approach in researching mathematics teacher conceptions, the repertory grid seems to be a promising tool that meets the demands in the context of mathematics education research. Especially in a domain where the research objects are intertwined in many ways, the repertory grid might help to better understand such multi-faceted phenomena. Furthermore, the data provided by a repertory grid can be analyzed from different angles as both qualitative and quantitative methods can be applied (Tan & Hunter, 2002). This does justice to a research area which in itself has multiple perspectives. As we discussed the methodological approach in general, the repertory grid per se is not limited by cultural aspects. Nevertheless, when designing it for a certain purpose the educational setting and background of the teachers should not be ignored. This especially concerns the selection of elements in a grid as all interviewees should be able to relate to them. Additionally, the elements strongly define the emerging data.

The presented methodological discussion for a repertory grid on teacher conceptions of argumentation should be seen as an example in the field of process-related mathematical thinking which can be adapted. Replacing the elements, respectively arguments and explanations, with student solutions to a problem-solving activity or with different mathematical models of the same real-world problem can open the door to a repertory grid focusing on teacher conceptions of problem solving or mathematical modeling. Moreover, at CERME10 it was discussed how teacher knowledge is related to classroom practice and students' learning (Ribeiro et al., 2017). This demand should probably not be limited to teacher knowledge, but should as well take teachers' beliefs, orientation or attitudes towards mathematical principles, concepts or ideas in an educational setting into account. Slightly adapting the presented grid design could be beneficial for exploring these relations further. Instead of fictional students' arguments, real arguments from the teacher's class could be taken. This would link the teacher's knowledge and beliefs directly to classroom practices.

Concluding the methodological discussion, we plan a qualitative interview study with German primary grade teachers on conceptions of mathematical argumentation. From a research perspective, our contribution hopefully enriches this research area which can surely take different paths. However, this discussion is a call for a methodology which takes strong interconnections into consideration, but does not lose the focus on the teacher as an individual being before exploring more general structures.

# Constructing tasks for primary teacher education from the perspective of Mathematics Teachers' Specialised Knowledge

Montes, Miguel<sup>1</sup>, Climent, Nuria<sup>1</sup>, Carrillo, José.<sup>1</sup>, Contreras, Luis Carlos<sup>1</sup>

<sup>1</sup> Universidad de Huelva, Huelva, Spain

miguel.montes@ddcc.uhu.es, climent@uhu.es, carrillo@uhu.es, lcarlos@uhu.es

*Developing tasks to help prospective teachers construct professional knowledge is an under-researched area of teacher education. In this paper we focus on describing the process of generating tasks in a research project at the University of Huelva. Using the model Mathematics Teachers' Specialized Knowledge we designed tasks to prompt the construction of specific elements of knowledge necessary for teaching mathematics, with the involvement of educators and prospective teachers selected ad hoc. As an example, we describe elements from a task focused on the notion of a polygon.*

*Keywords: Mathematics Teacher Education, Tasks, MTSK, Polygons.*

## Introduction

Mathematics teachers' knowledge has been the subject of discussion for over thirty years during which time various forms of modelling this knowledge have emerged, representing a wide variety of perspectives, foundations and proposals (see Montes, Ribeiro, & Carrillo, 2016). In this study we take on the challenge of applying insights from this body of research into professional knowledge to our teacher education programmes (Neubrand, 2018).

We are currently working on a research project at the University of Huelva which aims to develop a series of tasks for working with students following a degree in Primary Education. In the medium term, our objective is to structure the course content (with respect to mathematics) around research findings. Here we offer a progress report on the development of tasks for the prospective primary teachers which focus on the construction of professional knowledge, and which are underpinned by the research model, Mathematics Teachers' Specialised Knowledge (Carrillo et al., 2018). The first stage of development involved an experimental one-to-one teaching session (Cobb & Gravemeijer, 2008) with a specially selected group of students working alongside a team of experienced and less experienced teacher educators.

First we describe the theoretical foundations of the model of professional knowledge underpinning the study; then we give a detailed description of the first stage of the process for creating the tasks; finally, we offer some reflections on the development process, and the implications, limitations and potentials in taking it forward. This will contribute to give some light to our research question: how can a teacher's knowledge framework contribute to the design of tasks in teacher education? In particular, here we show the design process of a task concerning mathematical knowledge.

## Theoretical Foundations

There are three main aims in studying mathematics teachers' professional knowledge: enriching our understanding of its nature, evaluating its quality, and studying how it relates to performance through the study of competencies.

In terms of the first of these, the majority of models currently available attempt to identify the different components of knowledge which a mathematics teacher needs to carry out his or her work. Shulman's (1986) proposal, dividing teachers' knowledge into three broad domains (Subject Matter Knowledge, Pedagogical Content Knowledge, and Pedagogical Knowledge), has served as the basis for a multitude of subsequent conceptualizations offering more detailed subdomains, components and facets. Among these, the work of Ball, Thames and Phelps (2008) deserves mention for its identification of the kind of mathematical knowledge which distinguishes practitioners of mathematics education from all other professionals within the field of mathematics.

Among studies describing teachers' professional knowledge, particularly those focused on the extent to which teacher training enables teachers to construct the knowledge required for teaching the subject, we can highlight the TEDS-M comparative studies (Tattoo et al., 2008), which evaluate initial teacher training programmes, alongside the development of evaluative measures and instruments in studies at national scale (e.g. LMT – Learning Mathematics for Teaching – Hill, Ball, & Schilling, 2008, which aims to measure the knowledge of teachers practising in the US).

Finally, several studies have been carried out focussing on the connection between knowledge and action, in particular through the use of the notion of competence, understood as knowledge with the potential for use in different professional practices (Godino, Batanero, & Font, 2011). The aim of the research described here was to develop properly grounded tasks for training primary teachers consistent with design research centred on professional development (Cobb, Jackson, & Dunlap, 2016). Studies such as these draw on theoretical frameworks for the interpretation of how participants engage in the dynamic of professional development; in our case, we use the Mathematics Teachers' Specialized Knowledge (MTSK) model, developed by the team of educator-researchers who designed the task.

### Mathematics Teachers' Specialized Knowledge (MTSK)

The MTSK model derives from the aim to understand and analyse the teacher's knowledge specific to the teaching and learning of mathematics, and seeks to construct a detailed analytical tool. Since its inception (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013) the model has been discussed in various forums and we have given considerable attention to its theoretical foundations (e.g. Montes, Ribeiro, & Carrillo, 2016); at the same time, the model has been put to use with teachers in different educational contexts to analyse their work across a wide variety of mathematical content, and as a result, we have been able to develop a system of analytical categories within the subdomains constituting the model (Carrillo et al., 2018). The model itself contemplates three domains – mathematical knowledge, pedagogical content knowledge and beliefs and conceptions about mathematics and its teaching and learning, the first two of which acknowledge the legacy of Shulman (1986) and Ball et al., (2008), among others. Mathematical knowledge (MK) encompasses a thoroughgoing knowledge of mathematical content (Knowledge of Topics, KoT), its structure

(Knowledge of the Structure of Mathematics, KSM) and its syntax (Knowledge of Practices in Mathematics, KPM). Pedagogical content knowledge can be broken down into knowledge of mathematics teaching (KMT), knowledge of the features of learning mathematics (KFLM) and knowledge of mathematics learning standards (KMLS). As mentioned above, one of the features of the model that we would highlight is the detailed classification of categories within the subdomains, which enables the model to make a fine-grained analysis of the knowledge deployed by the teacher. Other features of note are the redefinition of mathematical knowledge and pedagogical content knowledge as intrinsic to mathematics; the integration of the teacher's beliefs into the model; and the intention to recognise that knowledge involves an intricate pattern of connections between subdomains.

### **Task design from an MTSK perspective**

In our view, the process of designing a task should involve representatives of all those participating, with different degrees of responsibility. In the case we present here, those involved were: three experienced primary educators with more than twenty years' experience in training and research into primary education; two primary educators with from five to ten years' experience in training primary and/or secondary teachers, both also researchers into mathematics education; two new entrants to teacher education with less than three years' experience, and in the process of completing their doctoral studies in the group; one student on a master's course who was studying the process; and three primary trainee teachers (PTTs), one in their final and two in their penultimate year of study. The educators constituted virtually the sum total of educators specialising in mathematics education at the University of Huelva. The PTTs were selected *ad hoc*, with an emphasis on those students with high grades in subjects related to mathematics, with a good capacity for reflection and analysis, a willingness and availability to meet with (part of) the team of educators, and a disposition to both provide and receive positive criticism regarding the training programme in which they were participating.

Tasks have a form, a function, and a specific focus (Grevholm, Millman, & Clarke, 2009). The task we describe here pertains to a set of teacher training tasks designed to stimulate the trainees' construction of professional knowledge of geometry, specifically the concept of a polygon. To achieve this goal, three tasks were designed around exemplification, the notion of a polygon, definition and classification. In acknowledgement of the potential of video as a tool for initial training (Schoenfeld, 2017), we decided that each set of tasks would be prefaced by a recording of pupils responding to some relevant mathematical content as a way of leading into the task. This obviously meant that any recorded material that might be used need to be carefully analysed first for its potential. In this instance, we used a recording of a teacher introducing her pupils to the notion of polygon by presenting a variety of cardboard shapes for them to group together and subsequently arrive at an acceptable definition of a polygon. The teacher included a number of non-standard shapes, and by presenting them as cardboard cut-outs, and hence non-static, she avoided the risk of standard positioning influencing the pupils. The video illustrated how the teacher acted as guide, largely leaving the pupils free to make groupings according to their own criteria, and encouraging them to reflect on these.

The process of planning the associated task followed several stages:

- 1) *Watching the video*: the three representative PTTs watched the recording and recorded their impressions against a checklist of the following items: teaching strategies used by the teacher; pupils' thinking strategies, intuitive ideas and difficulties; mathematical content in play and specific aspects of the content brought to the fore; task type; resources used – potential, limitations and use; appropriateness for the syllabus; examples given, representations of the content and resultant problems; teacher's knowledge of the content; teachers knowledge of the teaching and learning of the content. The checklist, drawing on the MTSK model, was designed to focus trainees' attention on relevant aspects of the excerpt while they watched, always with a mind to the mathematics involved. The PTTs were asked to follow up the viewing with an individual analysis in the form of a written report.
- 2) *Informal seminar*: The three PTTs met with one of the educators to discuss the video and identify the key items which had sparked their reflection. The educator took the role of interviewer, drawing out from the collaborating students their impressions of what they had watched. The aim of this session was to explore what the educators might reasonably expect trainee teachers to make of the recording, and in fact the PTTs' perception of the potential of the recording for use with trainees was also discussed, making them participants in the design process. The complete seminar was video recorded.
- 3) *Designing small group tasks*: The team of educators agree a focus for each of the three tasks and establish a sub-group for each one, making sure that each contains an experienced as well as a novice educator. The foci derive from areas of interest arising from the students' analysis (issues deemed by them to be relevant to their professional training). Keeping in mind the previously agreed objectives, each group selected the subdomains and categories of the MTSK model which they felt were most compatible with each objective, and created sub-tasks dealing with each objective, along with an 'ideal' solution to the problem specifying which elements of knowledge they expected to be brought into play (making reference to the MTSK indicators).
- 4) *Educators discussion group*: Each sub-group presented its task to the whole group, and this was discussed and refined, returning to step 3 if necessary. The discussion aimed to ensure that (i) the task matched the agreed objectives, (ii) the MTSK indicators facilitated the objectives, and (iii) the sub-tasks contributed to the construction of the elements of knowledge reflected in the indicators. The main objective of these discussions was to improve the task, but at another level there was a secondary aim to aid the development of the novice educators. When the task was generally considered to be ready to use, it was given to the PTTs to be carried out individually.
- 5) *Small group implementation*: Once the PTTs had done the problem individually, they met with an experienced and novice educator to talk through their solutions. The PTTs took turns to present their solutions, which the group then discussed, also taking the opportunity to consider any digressions from the task which the educator deemed interested. After the discussion, the PTTs were asked to reflect on (i) the potential and limitations of the task for use on their training programme, (ii) the likely response of their fellow trainees to the task and

how they would likely tackle it, and (iii) the extent to which they felt the task was appropriate to their training.

- 6) *Closing discussion*: All the educators met to evaluate whether the task had enabled the students to reach the agreed objectives. To do this, the knowledge deployed by the three students was measured against the MTSK model, on the basis of which the task was further fine-tuned into its final version ready to be used with the whole group, and was added to the collection of completed tasks. The process then looped back to stages 3 and 4 until the remaining tasks were completed in the same way.

One of the tasks, dealing with the definition of a polygon and focusing only on mathematical knowledge, is described below as an example.

In their analysis of the recording of the primary lesson on polygons, the PTTs provided contrasting definitions and images of a polygon. The key features they agreed on were that a polygon was a closed, flat figure with straight sides, and could be considered in terms of both the interior and boundary. To this extent they largely agreed with the definition which was constructed in the course of the lesson (a polygon “is a flat shape, it has angles, it has vertices, it has straight sides and no curves; all the sides are joined at their extreme points”), barring the tautological “straight lines and no curves”. They consider this definition to “be close to the correct one” (which, it seems they believe, is unique). They also dismiss size as integral to the concept of a polygon, differentiating between mathematical qualities (which play a role in the definition) and those qualities which they denominate “physical” (which play no role in the mathematical concept). They consider that a polygon has to have the same number of sides, vertices and angles. A doubt emerges as to whether a segment of curved line can be called a side (for example, can we say that a circular sector has three sides?). In this respect, one of the PTTs considers that “a curved side is infinite sides” since, as they go on to explain, “the circumference is the limit of a succession of polygons in terms of the number of sides.” For the educators, this contribution to the discussion represented an opportunity within the task for studying degeneracy. For their part, the PTTs recognise as polygons rectangles, squares, triangles, regular and irregular polygons, and concave and convex polygons; and they reject as polygons circumferences, circular sectors and polyhedra.

We saw the opportunity from the above to take the students further into the concept of polygon, its key features and possible definitions. With this in mind, we planned an activity which started by asking them to discuss different definitions of a polygon (giving examples of figures which complied with the definition and those which didn't). They were also asked to compare each definition with the one they had previously deemed correct. Below is a selection of the definitions they were given:

- a) A polygon is a flat figure with an edge.
- b) A polygon is a continuous line with an angle between each segment.
- c) A polygon is the flat region delimited by a jagged line where I can differentiate the inside from the outside.
- d) A polygon is the flat region delimited by a closed polygonal line, and which has the same number of vertices, sides and angles.

- e) A polygon is a region delimited by a closed polygonal line, such that given any two points on it, the segment joining the two is always within said region.

The aim of this activity was to encourage the PTTs to explore the properties of polygons, the interconnections between these, and what can be considered essential properties. In particular, it sought to highlight the notions of concavity and convexity, connected components, examples and counterexamples of polygons (KoT – definitions, properties and foundations), the uniqueness of a concept's definition and the equivalence of definitions (KPM), geometric vocabulary (KoT – registers of representation) and comparison of definitions (KoT – procedures). In the course of the activity, the PTTs become immersed in a process of coming up with examples and counter-examples, attempting to find what they themselves term 'unusual polygons'. Some of the definitions, such as (a) and (b), struck them as very natural; in others, such as (e), they had to think back to the case of concave polygons. The discussion of the remaining definitions led them to consider whether two shapes (Figure 1) were polygons.

**Figure 1: Shapes suggested by the primary trainee teachers**

Student 1: For me, the shape that looks like a 'set square' [referring to the technical drawing aid] is very striking. I think it is a polygon, but it's got that hole, which is 'unusual'.

Educator: And what would the sides be?

[Student 1 indicates the 'exterior' boundary]

Student 2: Yeah, it's the same for me, those should be the sides, but the ones inside... What could they be? It's the same with the two triangles joined at the base, is that one side or two? If you turn one of the triangles slightly, leaving them joined at the vertex, then they'd be two, but the number of vertices, sides and angles don't add up.

This debate led them to consider the relationship between sides, vertices and angles that a polygon must fulfil (KoT), or, more formally, the number of connected components that the interior of a figure should have in order to be a polygon (KoT). At the same time, they also recognised that in mathematics it is possible to look for relationships between different definitions of the same object so as to tell if they really define the same object (KPM). For the educator, this presented an opportunity to consider the limits of the degree of complexity that can be demanded from the students' understanding.

The discussion that ensued revealed it had been interesting for the PTTs to consider which of the figures – among those that struck them as common, or even particular to the interaction of the pupils

with the educational material (as in the case of the set square) – prompted a richer discussion of mathematics, and they recommended exploring examples such as these as a means of extending trainees’ knowledge beyond the standard examples of school mathematics.

In summary, the confluence of carefully developing the task, using the MTSK indicators, and drawing on the experience of the educators and the impressions of the specially chosen PTTs enabled professionally-oriented training tasks to be devised, which tap into the specific elements of specialised knowledge required for teaching. Including the contributions of prospective primary teachers in the development process will undoubtedly help to ensure that future students engage in the tasks with a high degree of motivation.

## Final reflections

One of the chief aims of primary teacher education should be the construction of the knowledge base which will enable newly qualified teachers to meet the challenge of their first classroom experiences with success. To this end, the work described here uses a model of professional knowledge to define suitable aims and points of focus. The model, MTSK, guides the choice of elements to include in the process of construction, such as the properties of polygons in the task described above (KoT), and the coordination of different definitions (KPM). A remaining challenge is how to evaluate the knowledge aimed to be developed with this task and the relationship between the elements of the task and the knowledge built, which will be addressed further. Likewise, we assume a second challenge, consisting in the necessity of scaling up from task designing for/with some PPT to design for ‘many’ of them (Prediger, Schnell, & Rösike, 2016).

A good starting point to face this necessity is the design of tasks developed from one-on-one teaching experiments (Cobb & Gravemeijer, 2008), which can then be presented to the whole group. The involvement of high profile PTTs for appraising the task in terms of its training potential provides an opportunity to collate suggestions on how it might be improved and implemented. Likewise, the dynamic of the discussion group, involving both experienced and novice educators represents a context for constructing trainers’ knowledge, MTSK also playing a structuring role in this training, as suggested by Kilpatrick and Spangler (2016).

# A Look into Turkish Preservice Teachers' Translation Skills: Case for Model Representations

Zeynep Pehlivan<sup>1</sup> and Fatma Aslan-Tutak<sup>2</sup>

<sup>1</sup>Bogazici University, Faculty of Education, Istanbul, Turkey; [zynpehlivan@gmail.com](mailto:zynpehlivan@gmail.com)

*Multiple representation enables students to connect different ideas and gain a deeper understanding of the mathematical concepts involved. The integration of mathematical model representation in order to model and interpret physical phenomenon and solve real world problems is one of the major objectives of mathematics learning in high school curriculum (NCTM, 2000). In this respect, this study focused on Turkish preservice teachers' process of translation of model representation among four representation types. The result of this study indicate that Turkish preservice teachers lacked knowledge on the competencies of translation to and from model representations. Results also indicate Turkish preservice teachers' tendency to use another representation type as transitional stage to model representations.*

## Literature Review

Employing multiple embodiments of the concept in the learning environment is essential in mathematics education not only its role in exemplifying abstractions but also creating a solid conceptual understanding of a single concept by illustrating interconnectedness between the representations. While the problems are analyzed, using different mathematical demonstrations such as creating table and graph or using algebraic expressions efficiently play a central role in the process of conceptual understanding as well as application of inquiry. In this respect, Friedlander and Tabach (2001) call attention to consider both advantages and disadvantages of each representation since in the case mathematics learning, the use of symbolic, tabular, graphical and modeling representations aids learners to create their mental constructions and lead the way to effective and meaningful learning.

In addition to applying multiple representations, the process of model representation is other fundamental components of mathematical education. Jacobson (2014) described the ability to model as requiring students to "use their understanding of arithmetic operations to make mathematical sense of problem situations and to relate this sense making to functions represented by equations, tables, and graphs" (p. 155). NCTM Standards (2010) for school mathematics emphasized that mathematical model representations encourage students learn how mathematics works in the real world and sense about what they have done during the mathematical process. NCTM Standards (2010) for school mathematics emphasized that mathematical model representations encourage students learn how mathematics works in the real world and sense about what they have done during the mathematical

process. In this sense, investigating Turkish preservice teachers' mathematical models helps researchers to a better understanding of how one simplifies, constructs and works mathematically on a problem, which are key elements of mathematical thinking. In light of this, the purpose of this study is to gain insight into Turkish preservice secondary school mathematics teachers' representational practices of mathematical models in the context of mathematical functions. The data collection process was completed before preservice teachers studied multiple-representation topic in the secondary mathematics teaching methods course. The purpose of this selection of data collection timing was purposeful in order to depict what secondary school teacher candidates would know without addressing multiple representations in methods class.

## **Methodology**

### **Participants and Settings**

This study is a part of a larger study that examined the Turkish preservice teachers' translation process among six representation models. Twenty-four senior-year preservice teachers from a public university in Istanbul voluntarily participated in this study. The students of this department had to took high scores from university entrance exam, in other words, these participants were successful high school graduates who has to score pretty high in mathematics. Furthermore, senior students of the department have to take various advanced level mathematics courses like group theory, analysis, probability and statistics from mathematics department of the university. Thus, the a common assumption for Turkish context is that the senior year preservice teachers from this department are pretty well equipped in terms of content knowledge. So, one purpose of this study was to investigate how mathematically high achieving preservice teachers perform in terms of translation between representations for functions, a central concept that they will teach.

A questionnaire was designed to address participants' way of representing combination of translation pairs among graphical, model, tabular and algebraic. The participants had to translate those modes univocally without the intervention of the researchers. In order to maximize return rates and ensure data trustworthiness and credibility, the researcher was in charge of recruiting and collecting data from questionnaire. In this sense, data collection process took place within one-hour research method course while the preservice teachers were attending the course early in the academic year under researcher's supervision.

### **Instruments**

The questionnaire questions were derived from manuscripts (Carlson et al. 2002; Leinhardt, Zaslavsky and Stein, 1990; Shell Centre for Mathematical Education (University of Nottingham) and adopted in Turkish by the researchers. Since this study was a part of a larger study, six questions particularly related to translation pairs including model representations were used in this research. The figure 1 below illustrates two of the examples in the questionnaire which illustrated translation from graphical representation to model representation and from model representation to graphical representation respectively. The question on the left side required participating preservice teachers to indicate which sport among fishing, pole vaulting, sky diving and javelin throwing. would produce a graph like in the given shape below. This question is related to translation from graphical representation to model representation. The other question on the right side asked preservice teachers

sketch a rough graph to demonstrate how the distance from A will vary with the distance from B and this question is related to translation from model representation to graphical representation.

Aşağıda verilen grafik hangi spor dalı ile ilgili olabilir? (Shell Centre for Mathematical Education (University of Nottingham), 1985)

Balık Tutma

Paraşütle Atlama

Cirit Atma

Ok ile gösterilen araçlar aşağıda gösterilen dairesel yol üzerindeki yönüyle takip ederek sabit hızla hareket etmektedir. Verilen modele göre aşağıda verilen grafikleri tamamlayınız. (Leinhardt, Zaslavsky, & Stein, 1990)

**Figure 1. Two tasks in the questionnaire**

After collection of 24 preservice teachers' results in the questionnaire, researchers decided to evaluate questionnaire data quantitatively, in which participants were scored by criterion referenced standards according to their translation scores. Total translation score reflects the sum of the translation score of participants and obtained by preservice teachers' score in translating among tabular, graphical, algebraic and model representations between a minimum score of 0 (indicating limited correct translation activity), a score of 1 (indicating a partially correct translation activity) and maximum of 2 (indicating correct translation activity). Limited correct translation activity included participating preservice teachers' mathematically incorrect attempts to translate into specified translation type. Partially correct translation activities comprised preservice teachers partially correct mathematical procedures and calculations in the given translation pairs. Preservice teachers who completed all procedures correctly were given correct translation activity score. The sample preservice teachers answer in the second question in Figure 1 are shown in Figure 2. The following examples in Figure 2 illustrates between limited translation, particular translation and complete translation points for the translation pair of from model representation to graphical representation.

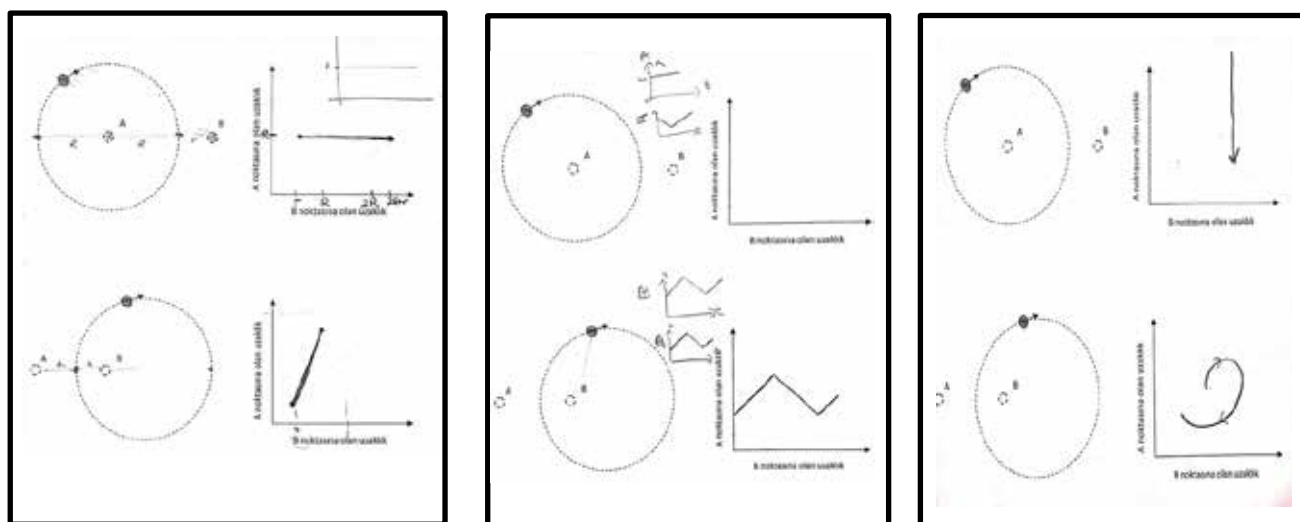

Figure 2. An example of correct translation activity, partial translation activity and limited translation activity respectively

While academic experts examined the items and provided comments and reflections for content appropriateness, a Turkish language teacher reviewed the questionnaire's grammar, punctuation, and word selection, and three experienced mathematics teachers checked the participants' responses to ensure interrater reliability.

## Results

As this study aimed to examine the Turkish preservice teachers' ways of translating from and to the model representation of functions, it was expected the Turkish preservice teachers to coordinate the given representations and model representations. The results of Turkish preservice teachers' responses concerning their translation scores in the questionnaire were summarized in Table 1.

Representation types	Limited Translation (0)	Partial Translation (1)	Correct Translation (2)
Model → Graphical	4 (16,66%)	13(54,16%)	7 (29,16%)
Model → Tabular	6 (25%)	15 (62,5%)	3 (12,5%)
Model → Algebraic	16*(66,67%)	8 (33,33%)	0*(0%)
Graphical → Model	9 (37,5%)	11(45,83%)	4 (16,66%)
Tabular → Model	6 (25%)	16 (66,67% )	2 (8,33%)
Algebraic → Model	4 (16,66)	13 (54.16 %)	7(29,16)

Table 1. Number of Turkish preservice teachers in each group

The table showed the number of preservice teachers in three categories that formed according to their scores in each translation types. The translation score reflects how accurate preservice teacher's translation process in which tabular, graphical and algebraic representations are mapped

onto model representations and vice versa. Preservice teachers were given a minimum score of 0 (indicating limited translation activity), a score of 1 (indicating a partial translation activity) and maximum of 2 (indicating ability to translate among multiple representations).

Besides, 24 Turkish preservice teachers' mean score for each translation pairs were presented in Table 2.

	Model → Graphical	Model → Tabular	Model → Algebraic	Graphical → Model	Tabular → Model	Algebraic → Model
Mean Score of Each Group	1,12*	0,87	0,33*	0,79	0,83	1,12*

**Table 2. Mean Score of Each Translation Pair**

According to Table 1 and Table 2, the translation pair from model representation to algebraic representation has the lowest rate in mean scores. The participating Turkish preservice teachers' ability to establish meaningful links from model representation to algebraic representation was considered weak. In parallel with this, 16 Turkish preservice teachers out of 24 got zero translation points when translating from model representation to algebraic representation whereas no participants could perceive the goal of making conceptual shift between these two kinds of representations.

However, translation pair from algebraic representation to model representation was recorded having the highest mean rate with 1,12. The question relating to translation from model representation to algebraic representation was based on cumulative quadratic functions whereas its reverse pair was written as an example of linear functions. When looking to participants' responses, Turkish preservice teacher was unable to define dependent and independent variables in the context of model representations in this translation pairs. In conclusion, we can easily conclude that the score of participant Turkish preservice teachers were accumulated in partial translation score which points their limited ability to translate among several representation types.

## Discussion

An important element of effective mathematics teaching at secondary school is using multiple representations and guiding students to translate between the representations (NCTM, 2000). Demonstrating model representation of functions is not only algorithmic process, it is also related to formulating problem situation, choosing appropriate variables according to given representations, determining the relationships between representations and verifying the model and its implication. Within this context, integration of model representation as mathematical practice in teaching and learning mathematics is targeted an area of interest in revised mathematics curriculum (MoNE, 2018). The department of curriculum studies of the Ministry of Education (Talim ve Terbiye Kurulu Başkanlığı, TTKB, 2017) identified symbolic, model, graphical and tabular representations as a way for developing appropriate solution strategies for real life problems. In this line, effective and fluent usage of model representation is an important practice associated within this goal. In that respect, this study is important since this research evaluated Turkish preservice teachers' translation ability from one type of representation to another.

Yet, as functions are the concept of interest in translation items, the results also shed light on the underlying algebraic ideas such as variable, covariation etc. behind the translation procedure. When examining participating Turkish preservice teachers' responses, they achieved to translate from algebraic representation to model representation, in which they were required to write a real-life example according to a linear equation. On the other hand, participants failed to satisfy necessary requirements to write a reasonable algebraic expression which is suitable for a quadratic growth. This evidence suggested that participating Turkish preservice teachers might have a lack of knowledge on functions since not only did they show difficulties to recognizing expressions in the different types of models, but also complications in explaining the models' specificities of the models in the context of tasks given. It is also important to note that participants had difficulty when stating independent and dependent variables in the graphical and algebraic representation. Thus, the results of this study support notion of addressing content knowledge in methods courses which have main purpose of mathematics teaching methods.

Furthermore, the findings collaborate with other studies reporting Turkish preservice teachers' difficulty with covariational thinking of functions (Carlson, Jacobs, & Larsen, 2001; Zeytun, Çetinkaya & Erbas, 2010). It is pointed in the literature that well developed understanding of function is possible by exploiting relationships between two variables (Carraher & Schliemann, 2002). Participants' limited conceptual understanding on functions cause them to struggle interpreting the given type of representations and finding a model representation.

## Prospective primary teachers' knowledge of problem solving process

Juan Luis Piñeiro, Elena Castro-Rodríguez and Enrique Castro

University of Granada, Spain

[juanluis.pineiro@gmail.com](mailto:juanluis.pineiro@gmail.com) - [elenacastro@ugr.es](mailto:elenacastro@ugr.es) - [ecastro@ugr.es](mailto:ecastro@ugr.es)

*Studies on teachers' understanding of processes such as problem solving have focused primarily on their beliefs and conceptions to the detriment of features indicative of their professional knowledge. This study analyses the knowledge about problem solving process revealed by prospective primary teachers. A questionnaire specifically designed for the study was administered to 61 undergraduates beginning and 53 ending their training. Although characterising solving as a dynamic process, both groups, in their description of stage characteristics and strategy identification, revealed that their knowledge was essentially theoretical.*

*Keywords: Problem solving, Teacher knowledge, Pre-service teachers*

Researchers have engaged in the study of teachers' knowledge in an attempt to identify the type of expertise required to teach mathematics effectively. Problem solving (PS) forms part of such expertise, as it is a fundamental process in classroom mathematics, which should cover both problem-solving skills and elements that help students become better problem solvers.

To teach PS, teachers need to know what to do, when to do it and the implications of their actions (Lester, 2013). Unfortunately, teachers have been found to exhibit limitations in that regard (Andrews & Xenofontos, 2015). Research in the area has targeted their ideas and their own problem-solving skills (Lester, 2013), eclipsing factors indicative of their professional knowledge. These considerations led us to pose the following research question: what knowledge do prospective primary teachers have about PS process? Specifically, this study analyses and describes the differences in the theoretical knowledge about the PS process exhibited by prospective primary teachers at the beginning and end of their training with a view to helping fill that gap.

### Teachers' knowledge of mathematical PS.

Mathematical knowledge for the teaching is understood as a wider knowledge than the mathematical subject. Therefore, "the knowledge needed to effectively teach PS should be more than general problem-solving ability" (Chapman, 2015, p. 19). Lester (2013) pointing out that the teachers' ability to solve complex, cognitively demanding problems does not suffice to guarantee appropriate PS instruction. In addition this author points out that it is necessary to clarify what aspects, other than the teacher's competence as a problem solver should be part of the knowledge of the mathematics teacher. However, shortcomings for determining teachers' professional proficiency with previous theoretical frameworks have been identified, regarding to overlap or the need to broaden the theoretical approach to supplement analyses. More specifically, research on teachers' ability to teach PS is not organised in the usual manner (Chapman, 2015), which leads among other limitations to omissions around the nature of PS (Foster, Wake, & Swan, 2014).

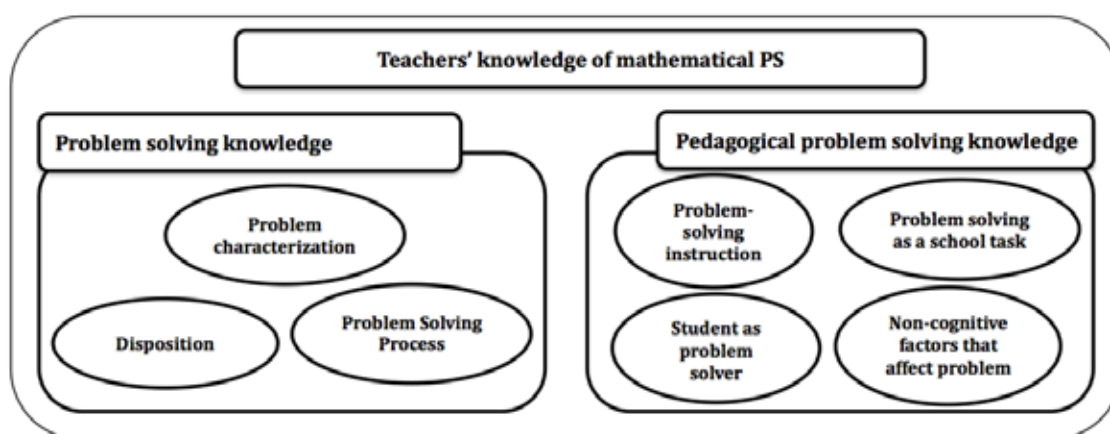

Teacher knowledge models have a tendency to be more content-focused, provoking the omission on some aspects of the nature of the PS. PS could be part of mathematics practice (in MTSK' terms,

Carrillo et al. 2018), in the sense that allows us to do mathematics (Codes, Climent, & Oliveros, 2019). Carrillo et al., (2018) establish that this sub-domain "encompasses teachers' knowledge of heuristic aids to PS and of theory-building practices" (p. 245). However, for a math task to become a problem, it necessarily needs the solver's perspective. PS is a process with personal nature, in which a problem is defined according to the solver. Under this perspective, tension emerges in the description of a mathematical knowledge disconnected from the students.

The knowledge for teaching PS in primary education needs to embrace more than the algorithms involved, how to apply them efficiently or possible mental calculation or representational strategies. To use the problem to its full potential teachers must also understand it as such, as well as the process for solving it. More specifically: a) the *problem*, i.e., the underlying mathematics, but also its type and format and the extent to which it may be a problem for students; b) *solving the problem*. The phases needed to solve: understanding what each data item means, how they are inter-related... But also is necessary the applicable strategies may vary, from algebraic; guess and check, or even tables or diagrams to visualise the relationships among quantities; c) the *disposition* it may generate in students; d) the *mistakes* they may make; e) the *potential* for developing cognitive features such as the various strategies, and non-cognitive features such as the belief that problems can be solved in different manners or that discussion of a problem is part of the learning process; f) the *changes* that can be made in the amounts of the variables or their inter-relationships to render the problem harder or easier; and g) classroom *organisation*, i.e., the approach to use or emphasise. Given that the characteristics of the problem accommodate the consideration of different strategies, prioritising teaching *about* PS would appear to be the most suitable approach.

Identifying professional knowledge about PS teaching calls, firstly, for addressing teachers' knowledge of processes rather than their mathematical content knowledge, the perspective adopted in traditional teachers' knowledge models. Based on mathematical and PS proficiency theories, PS is understood here to mean the action taken by a subject who identifies a problem, proceeds to solve it by deploying a strategy involving a series of not necessarily linear steps and confronts the challenge with a favourable disposition. Based on this idea, teaching PS proficiency draws on a complex network of interdependent knowledge. Chapman (2015) proposes a model consisting of a) teacher PS proficiency; b) knowledge of problem content, solving and posing; c) pedagogical knowledge of students as problem solvers and of teaching practice; and d) a dimension comprising affective factors and beliefs that impact teaching and learning this skill.

We have applied the Chapman's framework to six curricular guidelines in order to identify the knowledge required to teach PS (Piñeiro, Castro-Rodríguez, & Castro, 2016). This analysis has led to modifications (Piñeiro, Castro-Rodríguez, & Castro, 2019), in which we distinguish three elements on teacher's knowledge, its own proficiency to solve problems, and two related to teaching (one referred to PS theoretical knowledge, and another to aspects of learning and teaching). Figure 1 shows the components of our framework related to PS knowledge and PS pedagogical knowledge. Here we focus on teachers' PS process knowledge, distinguishes four key components: PS stages and their characterization, strategies, metacognition, and non-cognitive factors (Piñeiro et al, 2019). This study is confined with static knowledge related to PS, that is, the theoretical aspects of PS process (Blanco, 2004).

**Figure 1: Teacher knowledge components for teaching problem solving**

### **Theoretical knowledge about PS process.**

In our approach to Teachers' PS knowledge, PS process can be broken down into four areas: solving stages and their characterisation, solving strategies, metacognition, and affective factors (Piñeiro et al, 2019).

The first area, solving stages, adapts naturally to Pólya's (1945) postulates on how solvers proceed: comprehension, planning, action and evaluation. Awareness of those stages helps teachers adapt the assistance needed to the circumstances. One factor common to all four is their configuration as personal cognitive processes, not observable directly but only through what the solver says or does in each stage (Mayer & Wittrock, 2006). The process is non-linear, for as Wilson, Fernandez, and Hadaway (1993) explained, it is flexible, accommodating both forward and backward movements. Teachers aware of these elements can stand by their students and mediate in their development of PS proficiency.

In connection with the second area, solving strategies, Schoenfeld (1985) distinguished two types of decision-making. Strategic decisions include the definition of objectives and the decision to adopt a course of action. Tactical decisions are geared to implementing strategic decisions. Whilst together they constitute what is understood as strategy, singly they are of no use for a number of reasons, including the role of metacognition (Schoenfeld, 1985). Strategies must be taught carefully, for that endeavour covers all the overlapping components addressed in this section. More specifically, decision-making on what to do and how to do it depends on an understanding and mental representation of the problem. It is also affected by metacognition, for the success of the strategy is partly determined by its conscious use. Backtracking further reinforces this process and helps determine the aptness of the initial decision. The entire process is mediated by the emotions that may arise, the attitudes prompted and the beliefs held during PS.

The third area is metacognition. Schoenfeld (1985) expanded research perspectives by showing the importance of metacognition and affect. Metacognition is described as the manner in which solvers self-regulate, monitor, and control; their heuristics and mathematical knowledge to solve a problem, enabling them to apply appropriate decisions to the task at hand.

The fourth and last area covers non-cognitive factors and their essential role, for they determine how the solver confronts problems. It is generally agreed that depending on the suitability of the challenge posed to students, they bring their emotions into play, which in turn mobilises their intellect (Mason, 2016).

## **Method.**

To characterize the knowledge about PS of prospective primary teachers, we have used a questionnaire for the power that this type of instrument to collect information to, among others, describe the knowledge of the people (Fink, 2003). The questionnaire was designed and administered to university undergraduates beginning and ending their pre-service teacher training to analyse and describe the differences between them. A dual analysis was subsequently performed.

## **Context and participants.**

The participants in this study were 114 undergraduates working toward a degree in primary teacher education at the University of Granada. They were grouped by the training received, 61 first year (G1) and 53 fourth year (G2) undergraduates. G1 had received no university mathematics training. G2 had taken three requisite subjects on mathematics teaching: classroom mathematics content; teaching and learning core classroom mathematics topics; and the primary education mathematics curriculum. In these three subjects, PS is treated as a transversal goal. Specifically, when discussing meanings and modes of use of mathematical concepts. The activities in which they have involved are mainly of two types: master classes in which are presented, guided and synthesized some of the courses' topics. The second type, called practical activities can have two orientations, laboratory and TIC. In laboratory practices, work with manipulative materials, and TIC practices will focus on the management of educational software and Internet resources. They had also taken an elective addressing (among others) PS content, in which they were introduced to strategies and heuristics, problem posing and strategies for teaching PS. Specifically, in activities such as: a) characterization and exemplification of the role of PS in the learning of mathematics and its link with mathematical competence, b) development and application of strategies and heuristics for PS, c) application of criteria for posing problems, and d) analyze appropriate teaching strategies for teaching PS.

## **Instrument.**

The questionnaire was developed following phases: a) theoretical analysis on the notion of PS proficiency; b) study on the primary education curricular syllabus related to PR; c) research review about PS with primary teachers; d) construction of the pilot version of the instrument; e) review by expert judgment and pilot application; and f) construction of the final version of the questionnaire. These phases originate a specific questionnaire with two sections and 66 items. A closed binary design was adopted to elicit ideas that would denote the presence or absence of certain types of knowledge (Fink, 2003). The first section of the questionnaire (Figure 2) was sub-divided into PS stages and their characterisation, metacognition, and non-cognitive factors. The second sought to determine trainees' ability to recognise specific strategies in students' hypothetical answers to problems, in which, eight items were formulated as multiple choice questions. The options were: 1a) building a table; 1b) work backwards; 2a) draw a diagram; 2b) guess and check; 2c) look for a pattern; and 2d) operating.

<p>1. A student solved the problem set out below as shown:</p> <p>A dragonfly, the fastest-flying insect, can fly 50 metres in 2 seconds. How long would it take it to fly 375 metres?</p> <p>Dragonfly =&gt; 375 metres =&gt; time? → 1</p> <p>Dragonfly flies 25 metres per second → 2</p> <p>It needs 375/25 seconds to fly that distance → 3</p> <p><math>375:25 = 15</math> → 4</p> <p>It takes the dragonfly 15 seconds to fly 375 metres → 5</p> <p> <math display="block">\begin{array}{r} 25+25+25+25 \\ 25+25+25+25 \\ 25+25+25+25 \\ 25+25+25+25 \\ \hline 375 \end{array}</math> → 6 </p> <p>2. When solving a classroom mathematics problem, students advance toward the solution without backtracking.</p> <p>3. Problem solving is a dynamic process in which the solver backtracks if necessary to find the solution.</p> <p>4. Students solve problems step-by-step.</p> <p>5. Which of the following do you believe might be present when solving a problem?</p> <table border="0"> <tr> <td>a. Representing the problem</td> <td>b. Reading the problem</td> </tr> <tr> <td>c. Doing the operations</td> <td>d. Understanding the problem</td> </tr> <tr> <td>e. Exploring different ways to solve the problem</td> <td>f. Solving similar problems</td> </tr> <tr> <td>g. Verifying the solution</td> <td>h. Writing out the answer</td> </tr> </table> <p>6. A classroom mathematics problem must be understood to be solved.</p> <p>7. A solving plan can be suitably implemented without understanding the problem.</p> <p>8. Representing a problem in different ways may help understand it.</p> <p>9. Understanding a problem entails determining what information is available and how it is structured.</p> <p>10. Drawing a diagram or graph is a useful tool for understanding a problem.</p>	a. Representing the problem	b. Reading the problem	c. Doing the operations	d. Understanding the problem	e. Exploring different ways to solve the problem	f. Solving similar problems	g. Verifying the solution	h. Writing out the answer	<p>a. The problem was identified when the student described what the dragonfly does and the distance it needs to fly and posed the question about time. (Step 1)</p> <p>b. The student drew up the solving plan when mentally found the distance per second and proposed the operation: <math>375/25</math> (Steps 2 and 3)</p> <p>c. The student implemented the plan when divided 375 by 25. (Step 4)</p> <p>d. The student verified the answer when counted or summed up the metres per second. (Step 6)</p>	<p>11. A student solved this problem. Answer YES or NO to the assertions, as appropriate.</p> <p>A dragonfly, the fastest-flying insect, can fly 50 metres in 2 seconds. How long would it take it to fly 375 metres?</p> <p>As follows:</p> <ul style="list-style-type: none"> <li>- The dragonfly can fly 50 metres in 2 seconds</li> <li>- 4 seconds would be 100 metres</li> <li>- Then 6 seconds would be 200 metres</li> <li>- 8 seconds would be 300 metres</li> <li>- 9 seconds would be 350 metres</li> <li>- As there are 25 metres left, we put half</li> <li>- Then the dragonfly takes 9 seconds and a half to fly 375 metres</li> </ul> <p>a. No error, the answer is right.</p> <p>b. The student understood the problem.</p> <p>c. There are operational errors.</p> <p>d. The student verified the answer.</p> <p>12. When someone solves a problem they perform mental exercises that reveal when they've made a mistake.</p> <p>13. An awareness of one's own knowledge helps choose the most suitable way to solve a problem.</p> <p>14. When tackling a problem it's helpful to know several ways to solve it.</p> <p>15. A strategy is a procedure that guides the choice of the knowledge that should be used in each stage of a problem.</p> <p>16. Once a problem is solved, it's advisable for the solver to know what would happen if some of the data were changed.</p> <p>17. If a student finds the answer to a problem, no more action is needed.</p> <p>18. Re-reading the question after finding the solution helps determine the suitability of the procedures and the result.</p> <p>19. Once the answer to a problem is found, alternative ways to solve it should be sought.</p> <p>20. Identifying the characteristics of a problem enables solvers to create families of problems that can be solved in similar ways.</p> <p>21. It's important to know how to solve problems, but it's more important to want to.</p> <p>22. A problem can be successfully solved even when there's no motivation to do so.</p> <p>23. When students are confronted with a problem-solving situation, it's important for them to be motivated.</p> <p>24. Students don't need to want to solve a problem: what they need to do is listen to and obey the teacher.</p> <p>25. Students don't need to be interested in solving a problem. What they need is to understand the mathematical content.</p>
a. Representing the problem	b. Reading the problem									
c. Doing the operations	d. Understanding the problem									
e. Exploring different ways to solve the problem	f. Solving similar problems									
g. Verifying the solution	h. Writing out the answer									

Figure 2: Items on section 1 of the questionnaire

In the validation process, we contemplate two aspects. The first one is related to ensuring that the content is relevant and was made from the selection of knowledge related to PS on Primary Education school curricula. We have discussed this process somewhere else (Piñeiro et al., 2016). The second aspect corresponds to a test of the validity of the items, for which it was submitted to expert judgment. The experts' judgment makes possible a qualitative evaluation of the statements. Five Spanish mathematics education experts conducted the process. Also, a pilot application was made with the main goal was to increase reliability, validity and feasibility (Cohen, Manion, & Morrison, 2011). Our piloting was focused on assessing aspects such as the adequacy of the total time, clarity and comprehension of the statements.

## Analysis and results.

This study aims to characterize the theoretical knowledge about the PS process manifested by prospective primary teachers. This has motivated the use one of the forms of interpretation of multidimensional scaling, allowing identifying the groupings that emerge from their answers, describing the common feature of these and labelling the attribute present in them (Bisquerra, 1989). Therefore, respondents' replies were processed first with dimensional scaling multivariate analysis using ALSCAL (SPSS) software, in which the dimensions defined were *agreement* or *disagreement* with the item (from here on, these terms will be used only to refer to the dimensions found). A second descriptive analysis was subsequently performed, in which responses were reviewed in terms of inter-group differences and the ideas defended in the literature.

## PS stages and their characterisation.

This answers elicited high levels of agreement, although the percentage of agreement was higher in G2. Both groups acknowledged that the process could comprise several stages. For example, on the

stages' identification on a hypothetical solution, agreement percentages increase in the G2. Specifically, in the G1 a 97% identifies the understanding phase, 82% planning, 90% on carrying out the plan, and 80% on revision. In G2, 94% is the lowest percentage of recognition in any phases. At the same time, both groups characterize the process as flexible (98% in both groups), in which progress is made towards the solution (G1: 97%; G2: 100%), and they also admit the possibility of moving backwards if necessary (G1: 79%; G2: 83%). Both groups accept several moments on the PS process. Particularly, G1 states that, for example, representations (93%), reading (97%), calculations (95%) or verifications (95%) may appear. Likewise, in the same questions, the G2 presents positive answers in approximately 98% of the students. However, in this section one of the notorious differences can be found. In G1 only 46% respond positively to the possibility that similar problems can be solved, and 77% to the exploration of other resolution' paths. Conversely, G2 states that they can appear in 94% and 80%, respectively. On the questions that delve into the phases' features, there is majority agreement in both groups. For example, they recognize the usefulness of the representations to understand a problem (98%; 100%), and also that problems should not be solved without understanding them (97%; 98%). Nonetheless, in the questions that inquire about the value of the review phase, a difference was observed: only 49% of G1 state that it is advisable to pose similar problems, while 92% of the G2 states that it is necessary. Likewise, 67% on G1 indicates that it is appropriate to look for alternative forms of solution, as opposed to 91% on G2.

### **Knowledge of strategies.**

The strategies that best recognize G1 were: operating (95%), draw a diagram (92%), building a table (90%), and look for a pattern (74%). A lower identification' degree was found on strategies works backwards (64%) and guess and check (46%). The strategies that best identify on G2 were: operating (93.6%), draw a diagram (87.2%), works backwards (83%), and look a pattern (80.9%). The strategies that have a lower percentage of recognition were building a table (72.3%), and guess and check (40.4%). Interestingly, in G1, work backwards was mistaken for operating by 31% of respondents, whilst 34% confounded guess and check with building a table and 15% with look for a pattern. Similarly, 30% of G2 confounded guess and check with look for a pattern and 21% with building a table.

### **Knowledge of metacognition.**

Although most of the responses to the metacognitive items were agreement, a number of disagreements were recorded. Specifically, both indicate 92% state that the existence of monitoring that allows awareness of the errors committed. However, there are also some interesting answers. For instance, in one of the questions (11) on the reasons for operational errors in answers to problems, both groups identified the error. Their replies nonetheless differed about whether it should be attributed to a misunderstanding of the problem or to the calculation itself. In addition, both groups agree that the adequacy of the response was not verified.

### **Knowledge around non-cognitive factors.**

Most of the items on non-cognitive factors elicited agreement. The percentage of agreement was slightly higher among the G2, however. However, the agreement percentages are slightly higher in

the G2. For example, in a question that inquires into the disposition to solve a problem, 77% of the G1 agrees, while the percentage rises to 91% on G2. Also, there are some doubts that need to be highlighted. Disagreement was expressed in a number of items. In particular, although the future teachers in both groups deemed motivation to be important to PS, a smaller percentage believed it to be instrumental to a successful outcome. For example, both groups state that it is important to be motivated to face an PS process (G1: 90%; G2: 96%), however, only 39% on G1 and 40% of the G2 believe that this can determine success in finding a solution.

## **Discussion and conclusions.**

The findings showed that participants' replies were in line with the knowledge reported in the literature. They nonetheless co-existed with ideas that may prevent the translation of such knowledge into teaching practice.

Both groups' replies were consistent with a dynamic, cyclical interpretation of the stages described by Pólya (Wilson et al., 1993). The differences between the two groups studied in connection with knowledge of solving stages and their characterisation had to do with the variety of elements that may be involved in the solving process, specifically in the review stage. However, they do not consider posing problem as part of the PS process, one of the key moments to understand the process as cyclical (Wilson et al., 1993). That characterisation may fail to have practical implications, however, for the stages of PS about which respondents showed least agreement were the exploration of different solutions and problem posing. Given that those two approaches are determinants in characterising the process as dynamic and cyclical (Wilson et al., 1993), respondents may possibly be presumed to hold contradictory belief. Simultaneously, the present findings also seem to imply that the university training received has a scant impact on a command of PS theoretical knowledge, for the replies to the items on strategies between the two groups were essentially similar. The strategies with which both were most familiar were operating and drawing, whilst neither was well acquainted with guess and check. The inference is that although their knowledge was compatible with an understanding of solving as a dynamic and cyclical process, their approach continued to be linear. That conclusion is supported by the fact that the strategy least recognised, guess and check, is related to authentic PS.

In general, findings on teacher' PS process knowledge show little differences between groups. This seems to indicate that the knowledge they have, does not change during their training, despite having specific courses. This result could be explained because it is one of the areas stressed in curricula and textbooks (Wilson et al., 1993). Hence, we believe it is necessary for training programs to be concerned about this aspect, fostering skills that make it possible a deeper understanding of the PS process. On the other hand, the contrast between that finding and the actual belief exhibited by future teachers when confronting PS activities (Andrews & Xenofontos, 2015) raises the question of whether the relationship between mathematical knowledge and pedagogical knowledge is the same when a process such as PS is involved.

*In this paper, we discuss the process of conceptualising tasks for teacher education as a research methodology that may improve the understanding of the features of teachers' knowledge, as well as refine the specificities of the Mathematics Teachers' Specialized Knowledge (MTSK) conceptualisation. We focus our discussion on a task for teacher education conceptualised to develop teachers' knowledge of connections between measurement and fractions. The discussion of the process of designing a task emphasises the role of using a teacher's knowledge conceptualisation (MTSK) as a tool for such design, in a dialectic relation with the aim to develop a methodological tool to be employed in shaping teacher education and to develop teachers' knowledge.*

*Keywords: Teacher education, task design, teacher knowledge, mathematical connections.*

### Introduction

Teacher education involves a broad set of dimensions and may thus be investigated from different perspectives. One of the core aspects of mathematics teacher education is related to identifying the most problematic areas, not only in terms of the topics that present difficulties to both students and teachers—when learning and teaching, respectively—but also in terms of how the teachers' knowledge should be considered and developed.

It is well known that teachers' knowledge has a great impact on pupils' knowledge/learning (Grossman, 2010). In that sense, it is essential to focus teacher education on the core aspects of such knowledge, which demands a particular attention to both the process of conceptualising tasks and to how they are implemented. Moreover, it is necessary for the tasks conceptualised for teacher education to be in a direct relationship with practice, thus assuming a practice-based approach. One of the ways of achieving this aim is to include pupils' productions (containing errors or not but, in particular, those considered as non-standard), whenever aiming to contribute to the development of what has been termed as Interpretative Knowledge (Mellone, Tortora, Jakobsen, & Ribeiro, 2017).

Considering that the principles related to the school mathematics (NCTM, 2000) provide a set of five standards of mathematical process—connections, representations, problem solving, reasoning, and communication—teacher education must be concentrated on developing teachers' knowledge of those principles. Amongst them, connections and representations are particularly relevant for the work we are developing, as it focuses on teachers' knowledge. Since the representations and their use are directly linked to the learning process in mathematics, it is required to broaden and deepen the understandings about what kind of relationships can be established between various forms of representations, such as verbal, pictorial, numerical, symbolic, algebraic, and graphical.

In terms of mathematical topics in which representations play a central role, rational numbers are considered the most problematic, both in terms of learning and teaching, mainly because of the different meanings they assume across different contexts. When we consider the variety of interpretations of rational numbers—part-whole, measure continuous quantities, quotient, operator and ratio—it is not surprising that pupils experience difficulties in understanding and dealing with this concept. Besides that, because of the intrinsic relationship between the construct of rational numbers and the phenomenological process of measurement—since it is one of the meanings of the fraction representation for rational numbers (Charalambous & Pitta-Pantazi, 2005)—it is essential to focus on the connections between these two topics (rational numbers, fractions in particular, and measurement) in order to propose effective interventions in the context of teaching and learning, and specifically in the context of teacher education.

Considering, therefore, the central role that teachers' knowledge plays in pupils' learning, and the importance of improving such knowledge, allowing teachers to help students in developing the understanding about connections and (between) representations, this work focuses on the question: *which are the features required in conceptualising a task for developing the specificities of teachers' knowledge?*

## Theoretical Framework

Several conceptualisations of teachers' mathematical knowledge have been developed (e.g., Ball, Thames, & Phelps, 2008; Carrillo et al., 2018), most of which include, explicitly or implicitly, connections as a part of the dimensions of teachers' knowledge. This inclusion can be perceived as an awareness of the central role that connections assume in teachers' practice, for example, to establish a coherence on the work plan, that is, to the sequence of the tasks they prepare and implement. Another aspect related to the teachers' practice in which connections are essential is the need to give sense to students' productions (Mellone et al., 2017), treating them as a starting point to develop and broaden their mathematical knowledge.

We treat connections as a dimension of teachers' knowledge, which is related to the relationships teachers, consciously and deliberately, establish among different constructs within the same topic (intra-conceptual connections) and/or among different topics (inter-conceptual connections), in order to develop students' mathematical knowledge. In that sense, we assume a teachers' knowledge conceptualisation (Mathematical Teachers' Specialised Knowledge – MTSK – Carrillo et al., 2018) that considers such differentiation, both in terms of the type of connections, and the intentionality behind establishing such connections. The MTSK conceptualisation is conceived as a theoretical and analytical tool to better understand teacher's knowledge specificities, from two main dimensions, named Pedagogical Content Knowledge (PCK) and the Mathematical Knowledge (MK) domains. Each domain includes three subdomains related to: the content itself; the connections between topics and how one proceeds in mathematics (MK); the features of teaching and learning each topic and the awareness of the curriculum (PCK).

In this work, we focus on three of the six subdomains—Knowledge of Topics (KoT) and Knowledge of Structures of Mathematics (KSM)—related to, respectively, intra-conceptual and inter-conceptual connections and Knowledge of Features of Learning Mathematics (KFLM).

The KoT subdomain includes the teachers' knowledge on definitions, procedures, characteristics of results, foundations, properties, distinct types of representations, and phenomenology and applications. In the scope of rational numbers, it includes knowledge of the different meanings associated with the rational number (e.g., part-whole, ratio, operator, quotient, and measure – Charalambous & Pitta-Pantazi, 2005). Another aspect included in the KoT refers to the knowledge of the models and representations, for example, within contexts like percentage, ratio, and proportion, in which rational numbers can be applied. When a teacher establishes relationships amongst the

representations 50%,  $\frac{1}{2}$ , and , connecting them to the notion expressed by the term “a half,” and intentionally contextualises these representations in different situations, we would say that he/she reveals knowledge of intra-conceptual connections (KoT). In this context, the specialisation of the knowledge is related to connecting, intentionally and deliberately, the concept image (in the sense of Tall & Vinner, 1981) associated with a construct to its concept definition (as specific equivalence class), in each particular case, which is thus associated with intra-conceptual connections (KoT).

The KSM subdomain concerns the knowledge related specifically to (inter-conceptual) connections, and it comprises four categories. Because of the space limitation, we will discuss only two of such categories: the auxiliary and transverse connections. The auxiliary connection category is related to teachers' knowledge of the need to consider a notion (procedure or construct) as a support to the process of developing students' understanding of a certain concept (procedure or notion). In this case, we can take an example of a kindergarten teacher implementing a task involving a measurement activity, whereby he/she evokes the procedures of measuring (iteration of the unit and assigning a quantity to the number of times the unit fits within the whole).

The transverse connections pertain to the knowledge grounding the establishment of relationships between several topics with common features, even if those common features are not necessarily evident at first sight. An example of this concerns connecting the experience of measuring a magnitude, using different units of measurement, with the inverse proportional relationships between the number of units of measurement used and the correspondent values obtained for such measurement. In this case, considering the same whole, the smaller the unit of measurement, the bigger the number expressing the result of the measurement.

In relation to the work we are developing focusing on teachers' knowledge on connections, one other core aspect concerns the knowledge on students' mathematical thinking, learning and knowledge development when engaging with mathematical tasks, which is part of the KFLM subdomain from the MTSK conceptualisation. It also includes the knowledge of the types of tasks and examples, and common errors or areas of difficulty, as well as misunderstandings and misconceptions when proceeding in mathematics. For instance, a teacher should know the students' misunderstanding of a rational number as a measurement (quantity) and not only as a part-whole relationship.

Such specialised knowledge grounds teachers' practice, and in order to develop such practice having as a starting point what their students know and how they know it, it is required that the teachers interpret and give meaning to the students' productions and comments. When considering teachers' knowledge required to interpret students' productions, the notion of Interpretative Knowledge (IK)

has been developed (Mellone et al., 2017). It is defined as “the knowledge that allows teachers to give sense to pupils’ answers, in particular to ‘non-standard’ ones, i.e., adequate answers that differ from those teachers would give or expect, or answers that contain errors”, (Mellone et al., 2017, p. 2949). The aim of the educational process should be to develop teachers’ IK, so that they transition from an evaluative perspective (traditional—associated with a teacher’s establishment of a relation between the students’ answer and the elements of his/her own (im)possible and mathematically (in)adequate set of solutions for a problem, named *space of solutions*) to a real interpretation for the educational design, that is, when a teacher “revises his/her mathematical formalization in order to ensure that it is coherent with students’ productions” (Mellone et al., 2017, p. 2950).

Considering, therefore, the specificities and particularities associated with teachers’ knowledge, in the context of teacher education, the tasks conceptualised to develop such knowledge must also have a specialised nature (Ribeiro, 2016). This means that the MTSK and the IK perspectives, as tools for supporting the process of designing tasks conceptually, on one hand, aim at accessing and developing some aspects of the specialised knowledge related to the mathematical topic(s) to be taught. On the other hand, including students’ productions from which the mathematical reasons that sustain eventual errors or non-standard responses can be explored, the task conceptualisation relies on the notion of broadening teachers’ *space of solutions* and, ultimately, developing teachers’ ability to support the development of pupils’ mathematical knowledge, starting from their own reasoning.

## Context

The current work is a part of broader research project which focus on the dimensions of teacher’s knowledge related to connections. The goals of such research project include identifying and describing some categorisations of connections that teachers elaborate (or should be developed) when discussing tasks specifically conceptualised for teacher education.

All the tasks conceptualised are conceived to be implemented in different contexts of teachers’ training programs and they comprise of two parts (described in detail in the next section). The first part of the task discussed in this paper (denoted as “A half”) was designed to last about four hours, including both teachers’ reflections and the whole group discussions. The second part of the task was designed to last about two hours, also including teachers’ reflection and the whole group discussions.

## Analysing the conceptualisation of a task for teacher education

The MTSK conceptualisation considers, as mentioned before, six subdomains of teacher’s knowledge, with several associated descriptors. When conceptualising a task for teacher education using the MTSK as a tool for approaching the complexity of teachers’ knowledge, those descriptors will serve as guiding principles for the work of accessing and developing (this last process occurring specifically in the context of the task implementation) teacher’s specialised knowledge. Thus, after identifying the mathematical subject matter to be explored in the task, the task designer must choose the main aspects of teacher’s knowledge he/she wants to develop, and then must associate it to the descriptors included within the subdomains.

For instance, one of the questions of first part of the task (named “A half”) aimed at accessing (and not assessing) teachers’ knowledge of the meaning of the concept/construct of “a half”: a rational

number that can be understood as a quantity resulting from the phenomenological process of measurement; the meanings of a fraction; and/or result of a division (operation – which is a mathematical process). *“Imagine you are on the street and someone stops you and poses a question: ‘What is a half?’ What would your answer be? Respond to this question for yourself, using your own mathematical knowledge.”*) – KoT. Another question included in this part of the task aimed at accessing teachers’ knowledge about types of representations associated with a concept (*“Present two distinct representations for ‘a half.’ Justify why you consider these representations as distinct from each other.”*) – KoT. Moreover, they were considered in the first part of the task the type of problems/different contexts the concept/construct of fraction can be applied to, and procedures associated with, the characteristics of the result (number sense – number as a quantity) contexts in (*“Pose two distinct situations (or word problems) in which the term (and the concept) ‘a half’ is explicit.”*) – KoT and KFLM.

As the background of the aspects approached of the questions aforementioned, they were considered as contents of the teacher’s knowledge to be accessed the role of the whole when measuring and the foundations of the measuring activity (What is “to measure” something? What can be measured?) – KSM.

The conceptualisation involved in the tasks we have been assuming for teacher education includes the perspective that any situation students would encounter must be experienced by the teachers. In the “A half” task, two situations for students were included, denoted as “The secret envelopes.” Specifically, three different envelopes containing a stick and a piece of string are distributed to students and each pupil is asked to measure the stick using a piece of string. In the first situation, the three envelopes contain sticks of the same length, but the length of the strings corresponds to 4, 2 and  $\frac{1}{2}$  of the stick length, respectively. In the second situation, the envelopes contain both sticks and strings of different lengths, but the relation between the stick and string lengths in each envelope is always  $\frac{1}{2}$ .

Teachers are stimulated to solve the students’ task by assuming that they are not involved in a teaching context. Then, they are invited to reflect on the teaching process involved in the students’ task from questions explicitly linked to PCK subdomains. For doing so, questions such as *“What kind of knowledge do students need to solve the task?”* and *“How do you consider a 2nd grade student would solve the task? Try to present some examples of possible difficulties, mistakes, or misunderstandings a child could experience.”* are posed – KFLM.

In order to access teachers’ knowledge on: i) connections between the measurement process and the concept of a fraction as a number (quantity) including the different types of representations associated to it (KoT); and ii) connections between the inverse proportional concept and the characteristics of results obtained by a measurement process (KSM) a question linked to the students’ task was included (*“What are the mathematical topics/contents (that can be) explored within these tasks? Do you consider those topics/contents as related to each other? Give examples.”*).

The second part of the task is conceptualised according to the IK perspective (Mellone et al., 2017). For doing so, a transcription (Fig. 1) of a discussion between a teacher and a 2nd grade for “the secret envelopes” is presented<sup>1</sup>. Teachers are invited to interpret the last student’s statement, considering the mathematical adequacy and correction. They are subsequently instructed to propose a continuity of the dialogue to develop the student’s mathematical knowledge related to the topic of the task.

**Part II**

During “The secret envelopes” task implementation with a 2<sup>nd</sup> grade children, teacher Alice has a dialogue with one of her students, as it is followed:

**Alice:** *Matheus, how many [pieces of] string you needed to measure the stick?*

**Matheus:** *I need a half...*

**Alice:** *Cool. So, you go back to your seat and do not tell anything to the girls, right? You must keep this secret! You only must keep this number in your mind, so that we can discuss after, ok?*

**Matheus:** *Number? Which number? A half is not a number.*

**Figure 1: The second part of the “A half” task**

When interpreting the last student’s statement, teachers must evoke their MTSK related to the meaning of the construct “a half”, that is, as a rational number that can be represented by a quantity (resulting from the phenomenological process of measurement). This teacher’s specialised knowledge is associated to the KoT and KSM subdomains explored on the first part of the task. For instance, if in the first part of the task a teacher provides a representation of “a half” that is somehow associated with a magnitude (length, for example), he/she would be able to understand that the student is not comprehending the construct “a half” as a number because he/she is not considering a number as a magnitude (a quantity yielded by a measurement process).

One of the principles of the measurement process is to attribute a value to the measure, that is, a number. Therefore, in order to develop student knowledge about the number sense related to the concept “a half,” teachers should be aware of the need to redesign the educational process (Mellone et al., 2017), establishing connections among the numeric representation  $\frac{1}{2}$ , the pictorial representation , and the notion of a phenomenological process of measuring. Moreover, a teacher should be reflecting on how the special role played in the society by the rational number  $\frac{1}{2}$  is reflected in the natural language. Indeed, in many (all?) languages, we can find at least two ways to express it, like “a half” and “one on two”, and while this second way suitably arranged works for all the fractions, the first is only for  $\frac{1}{2}$ , stressing its special role.

Obviously, this (re)design of the educational process is associated with teachers’ specialised knowledge about the connections, both between different types of representation of a construct (in this case “a half”) and the meaning(s) of such construct (fraction as a measure). In that sense, it is important to highlight that, in order to develop the IK in teachers, it is necessary to simultaneously develop their MTSK.

---

<sup>1</sup> In the context of a task conceptualisation we have been developing, students’ responses as written or oral commentaries are considered as “student productions.”

## Final Comments and Remarks for the Future

In this paper, we presented a process of conceptualising a task based on a methodological and analytical tool focusing on the teachers' specialised knowledge (MTSK) and its relation to the process of intentionally developing their Interpretative Knowledge. Considering the features of the teacher's knowledge—which differs from students' knowledge and from that well-educated individuals possess—tasks aimed at teacher education must explore and develop the diverse dimensions and features of such knowledge (specialised and interpretative). The first part of the task involves a combination of the knowledges the students are expected to possess that is rooted in a deeper, formal, and rigorous understanding. The second part of the task is conceptualised by the IK perspective and is essential the inclusion of student's productions, preferably those in which the mathematical aspects can be explored in a broaden and deepen way.

When implementing a task conceptualised from these two perspectives about teacher's knowledge in a teachers' training context (initial or continuous), it is essential to emphasise the role of the teacher educator, who must be aware of the need for improving the specialised and interpretative teachers' knowledge. This should be done by not only following the questions posed in the task, but also by scrutinising the diverse types of (possible) interactions that teachers should present with the task. This awareness that teachers' educator must provide during the implementation is related to both his/her own mathematics specialised knowledge about teachers' knowledge and his/her own Interpretative Knowledge. In the context we have been working, the teacher educator (who is also a researcher) uses the particularities of both teacher's knowledge perspectives (MTSK and IK) as conceptual bases in the process of designing the task, implementing it in the teacher's training programs and analysing the data gathered from such implementation.

**Figure 2: Relationships to be considered in teacher education**

The process of conceptualising a task for teacher education described here is one of the several ways to perceive the methodology of designing tasks aiming at accessing and developing the specificities of teacher's knowledge. Both MTSK and IK perspectives are in process of development in different contexts (Spain, Norway, Italy, Brazil, etc.). In that sense, it is understandable (and desirable) that different teacher's knowledge conceptualisations are being used as tools for designing tasks for teacher education, from different perspectives (e.g., Montes, Climent, Carrillo & Contreras, 2019). In the context of the broad research we have been developing, we have been considering it extremely relevant to focus on the relationships between what we consider to be three pillars which sustain the process of

conceptualising a task for teacher education: the task design process and its implementation; the task implementation and the analysis; and the results of the analysis and the task design process. All these aspects are certainly influencing and are being influenced by the MTSK and IK perspectives, since both perspectives are considered in a dialectic relation with the aim to develop a methodological tool to be employed in shaping teacher education.

## Kindergarten teachers' knowledge in and for interpreting students' productions on measurement

Milena Policastro<sup>1</sup>, Miguel Ribeiro<sup>1</sup> and Alessandra Rodrigues de Almeida<sup>2</sup>

<sup>1</sup>State University of Campinas – UNICAMP, Brazil; [mitapolicastro@gmail.com](mailto:mitapolicastro@gmail.com); [cmribas78@gmail.com](mailto:cmribas78@gmail.com)

<sup>2</sup>Pontifícia Universidade Católica de Campinas, PUCCAMP, Brazil; [alessandraalmeida628@gmail.com](mailto:alessandraalmeida628@gmail.com)

*Keywords: Teacher's interpretative knowledge, Measurement.*

One of the core aspects of teachers' practice grounds (at least should) on the need to interpret students' productions and comments, not only for helping pupils to overcome their possible difficulties, misunderstandings or explore alternative approaches but also to (re)design the teaching approaches having such aspects as a starting point. Such knowledge required in and for interpreting students' productions has been termed as Interpretative Knowledge – IK (Jakobsen, Ribeiro, & Mellone, 2014). The IK is perceived as the knowledge that allows teachers to “give sense to pupils' answers, in particular to ‘non-standard’ ones, i.e., adequate answers that differ from those teachers would give or expect, or answers that contain errors” (Mellone, Tortora, Jakobsen, & Ribeiro, 2017, p. 2949).

Such IK needs to be (and it is desirable it is) developed in the context of teacher education, since it does not developed merely with teaching experience (Mellone et al., 2017). Such development requires to explore, in the context of teacher education, tasks specifically conceptualised to such aim<sup>1</sup>. One of the perspectives included in the tasks conceptualised for teacher education is related to teachers' anticipation of student's responses, a process associated with accessing teacher's *space of solutions* (Di Martino, Mellone, Minichini, & Ribeiro, 2016). Essentially, IK is related to the teacher's Mathematical Knowledge (MK) evoked when analyzing a student's production– which does not exclude his/her Pedagogical Content Knowledge (PCK) in this process. Moreover, anticipating student's responses plays a central role on the process of developing the IK, and it is also related to teacher's MK and PCK, as this capacity of anticipation depends, among other aspects, on his/her knowledge of different procedures associated to a concept, and students difficulties and facilities related to a mathematical topic. Besides, anticipating student's responses is associated with the feedback teachers would provide to students, that is, the set of decisions to be taken in order to implement significant mathematical practices. Amongst the mathematical topics teachers need to cover, measurement assumes (or it should) a major role since it is a core construct of mathematical learning, as it serves as a “bridge between the two critical domains of geometry and numbers” (Clements & Sarama, 2007, p. 517) and research shows that early cognitive foundations are not limited to number concepts. With such a core role in students' understanding, measurement is one of the topics needed to be explored with pupils since kindergarten—in order to allow them to start grounding their mathematical understanding and knowledge since early age. The content and nature of teachers' knowledge shape the learning opportunities provided to pupils (Hiebert & Grouws,

---

<sup>1</sup> For more information on such tasks conceptualisation see, for example, Policastro, Mellone, Ribeiro and Fiorentini (submitted).

2007), and researches focusing on kindergarten teachers' knowledge on measurement and its impact on students' performance (Grossman, 2010) is scarce. In that sense, we assume as one of the foci of attention in the research we are developing, the role of such knowledge in supporting (or inhibiting) the development of pupils' mathematical knowledge. In the context of a broader research project (in a continuous professional development context) we have been working with five kindergarten and primary teachers focusing on discussing some tasks with students' productions (aimed at improving their IK) in the scope of measurement. In a posterior moment the group prepare, discuss and implement tasks in their classrooms and afterwards a process of reflection upon the implementation occurs. In this poster we focus on presenting and discussing the methodological approach for the research. Complementary we discuss one episode emerging from the implementation of one of the tasks (with a group of 5-year-old pupils) focusing on one of the teachers IK when giving meaning to a student comment on "measuring a wale". The results of this study enhance the role of teachers' interpretative knowledge as one of the pillars that sustains the capacity to engage children in a mathematical discussion. The interrelationship between anticipating students' answers and the set of answers teachers would provide, allow them to make informed decisions and implement significant mathematical practices even in contingency moments.

# Developing an identity as a secondary school mathematics teacher: Identification and negotiability in communities of practice

Kirsti Rø

Norwegian University of Science and Technology (NTNU), Norway; [kirsti.ro@ntnu.no](mailto:kirsti.ro@ntnu.no)

*The paper reports from analyses of one Norwegian secondary school mathematics teacher (Isaac) in his transition from university teacher education to employment in secondary school. The process of becoming a mathematics teacher is studied in terms of identity, based on the teacher's participation within and at the boundaries of communities of practice at university and school. Adopting a longitudinal case-study design and methods from narrative analysis, the case of Isaac displays tensions between desires for own mathematics teaching and experiences of possibilities in practice. The case illustrates how the concept of identity is helpful for gaining insight into mathematics teachers' ability and legitimacy to contribute to, and take responsibility for, the meanings that matter regarding mathematics, its teaching and learning, in their professional debut.*

*Keywords: Identity, community of practice, secondary mathematics teaching, narrative analysis.*

## Introduction

Mathematics teacher identity has been explored from a range of theoretical perspectives, spanning from categorising aspects of teacher identity in order to describe it and better understand the possible influences on teachers' practice, to viewing identity as a function of participation in different communities of practice (Beauchamp & Thomas, 2009; Darragh, 2016; Lutovac & Kaasila, 2017). In their overview, Beauchamp and Thomas (2009) find identity to be considered across the literature as dynamic and a constantly evolving phenomenon, being under the influence of a range of individual and external factors. They discuss a variety of issues that surface in the attempt of defining the concept of identity: the role of agency and emotion in shaping identity, the power of stories and discourse in understanding teachers' identity, and the contextual factors that promote or hinder identity development. Similarly, Lutovac and Kaasila (2017) find studies on mathematics teacher identity to address multiple themes, for instance theoretical models for defining identity, affective relationships with mathematics and changes in teacher identity, and the link between identity and teaching practices. However, studies focusing on social practices and structures within which teacher identities develop seem to predominate in the research field. In this paper, I adopt identity as a theoretical concept for better understanding the participative experiences of one newly educated mathematics teacher, when entering a secondary mathematics classroom. The purpose of the study is to gain insight into the dynamics of one mathematics teacher's learning, as he moves across different mathematics practices at the university and at school and unites his experience into a role as a secondary school mathematics teacher. According to Palmér (2013), studies on mathematics teachers often provide an external perspective, where the researcher observes and evaluates teaching in order to describe the teacher's knowledge and/or beliefs across contexts. However, in order to understand better mathematics teachers' challenges and opportunities when entering the profession, I instead search for in this paper the individual teacher's own meaning-making of himself as an actor of mathematics teaching, and the development of this meaning-making in the professional debut. Studying teacher

learning within and across practices, the notion of identity becomes then a conceptual tool for investigating how a mathematics teacher negotiates meaning with others and how he regulates his participation according to reactions of others to him (Ponte & Chapman, 2008). The research reported is based on a larger study of three Norwegian secondary mathematics teachers' entrance into the teaching profession (Rø, 2018), from which the overarching research question is: *How do three prospective secondary school mathematics teachers identities develop in the transition from university teacher education to school?* In the subsequent section, I present the theoretical basis for investigating mathematics teacher identity, in which it is considered as a dual process of identification and negotiability from participating in communities of practice (Wenger, 1998). Adopting a longitudinal case-study design and methods from narrative analysis, I further report on and discuss results from a series of interviews with one newly qualified mathematics teacher, Isaac, during his first year as an upper secondary school mathematics teacher. Thus, this paper seeks to answer the following sub-question: *What are the participative experiences of one newly educated mathematics teacher, when entering a secondary mathematics classroom?*

### **Mathematics teacher identity in communities of practice**

Within the frames of Wenger's (1998) social learning theory, a prospective mathematics teacher's movement between university teacher education and employment in school implies various forms of participation in communities of practice, and the work of reconciling memberships across the community boundaries (Akkerman & Bakker, 2011). The concept of *community of practice* refers here to a set of relationships between people, who share some kind of competence through interaction, communication and negotiation of meaning (Wenger, 1998). When moving between practices, the prospective mathematics teacher is then negotiating ways of being a person in a community, e.g. being a student teacher in mathematics, being a schoolteacher, a teacher colleague, and an employee. Hence, the existence of a community of practice concerned with mathematics teaching and learning is a negotiation of related identities. On this basis, Wenger (1998) defines *identity* as negotiated experience of self when participating within and between communities of practice. Developing an identity as a mathematics teacher can thus be characterised as "increasing participation in the practice of teaching, and through this participation, (...) becoming knowledgeable in and about teaching" (Adler, 2000). A gradual change in participation, from the periphery towards the centre of a community of practice, is by Wenger (1998) described in terms of three modes of belonging: engagement, imagination and alignment. For instance, a prospective mathematics teacher might *engage* with ideas of inquiry based mathematics teaching through involvement in communicative practices with other community members (e.g. teacher educators, tutors, fellow student teachers, students in the classroom, teacher colleagues) during teacher education or in school. Consequently, he takes part in ideas of mathematics teaching through *imagination*, by envisioning himself as a teacher in a future classroom who is implementing the community's practice. Doing what it takes to play part in the community, the prospective teacher also *aligns* with the conditions or characteristics of the community's practice. This can take place through reading and sharing relevant literature with other actors, implementing inquiry based activities in own mathematics teaching and being involved in professional development projects on inquiry based mathematics teaching. Further, each of the three presented modes of belonging can be a source of the dual process of identification and

negotiability (Wenger, 1998). *Identification* concerns a person's investment in various forms of belonging to community practices, being both participative ("identifying with") and reificative ("identifying as"). In other words, identifying *with* a mathematics teaching practice or a group of actors of mathematics teaching is simultaneously a process of being identified *as* a special kind of mathematics teacher. Processes of identification with community practices thus define which meanings matter to the prospective teacher regarding mathematics teaching and learning. As an example, a mathematics teacher can identify himself with a community of inquiry based mathematics teaching by aligning with a joint learning objective of facilitating students' mathematical confidence and social empowerment. These learning objectives are related to perspectives of the subject of mathematics as being a social construction: "tentative, growing by means of human creation and decision-making and connected with other realms of knowledge, culture and social life" (Ernest, 1991, p. 209). Through inbound participation in the community, the teacher's identity will then develop in correlation with the negotiated perspectives on the nature of the discipline. However, processes of identification does not determine the teacher's ability to negotiate these meanings. *Negotiability*, then, refers to the "ability, facility, and legitimacy to contribute to, take responsibility for and shape the meanings that matter within a social configuration" (Wenger, 1998, p. 197). As an example, the meanings that a mathematics classroom community (teacher and students) produce of mathematics, its teaching and learning, are not only local meanings. They are also part of a broader *economy of meaning* in which different meanings are produced in different locations and compete for the definition of what mathematics teaching and learning is or should be. Consequently, some meanings of mathematics teaching and learning achieve special status. Wenger's (1998) notion of *ownership of meaning* refers here to the teacher's or the students' ability to take responsibility for negotiating the meanings of mathematics within the classroom community. The interplay between the mathematics teacher's expressed identification and his voiced negotiability displays therefore possible tensions between how he desires his mathematics teaching to be and what he experiences as possible in practice. Thus, it gives insight into the characteristics of mathematics teacher identity development in the beginning of a mathematics teacher career.

### **A narrative approach to mathematics teacher identity**

Taking an operational approach to the concept of identity, I follow Elliott (2005) and Sfard and Prusak (2005), who link identity to the activity of communication. According to them, narratives provide the practical means by which a person can understand himself as living through time, and thus, make identity accessible and investigable. Through a narrative lens, a prospective teacher can make sense of his process of becoming a mathematics teacher by selecting elements of experience regarding mathematics teaching and learning, and patterning the chosen elements in ways that reflect stories available to the audience. This temporal characteristic of narratives is in line with Wenger's (1998) interpretation of identity as a *learning trajectory*, when incorporating "the past and the future in the very process of negotiating the present" (p. 155). Similarly, Carter and Doyle (1996) state that a narrative approach to identity emphasises the negotiated nature of becoming a mathematics teacher. Mathematics teacher identities are not simply formed by life experience prior to, during or after teacher education programmes. Rather, the teachers are active participants in interpreting their experience, "searching for and constructing images that capture the essential features of their

understanding of the tasks they encounter in [mathematics] teaching” (Carter & Doyle, 1996, p. 134). This paper presents identifying narratives of one newly educated mathematics teacher (Isaac), based on three consecutive semi-structured interviews distributed across his first year as a mathematics teacher in upper secondary school. Inspired by Elliott (2005), each interview was introduced by an invitation to talk freely about experiences from undergoing subject studies in mathematics, university teacher education, and/or experiences from being a newly qualified mathematics teacher. To cover important parts of Isaac’s life as a learner and teacher of mathematics, the storytelling was followed by questions outlined in an interview guide. The follow-up questions concerned Isaac’s first mathematics teaching experience, memories of good and less good mathematics lessons, peaks and disappointments regarding mathematics teaching and learning, and his expectations about the future. Adopting methods from narrative analysis (Polkinghorne, 1995), I sought to create coherence across themes and plots in what was told throughout the interviews. I divided the interview transcripts into segments where a certain topic was discussed. Based on comparison and contrast of the segments within and across interviews, I developed labels due to the segments’ thematic focus. Further, I sorted the labels into greater categories or *emergent themes* of Isaac’s accounts. The emergent themes developed from analysis of the first interview were brought into the analysis of the second interview, being confronted by labels given to segments in the transcripts. If necessary, the emergent themes were refined or new themes were developed. The narrative analysis led to three emergent themes in which Isaac’s building of a mathematics teacher identity is expressed: *confidence in mathematics and mathematics teaching*, *perspectives on mathematics and its role in mathematics teaching* and *feedback available within the school environment*. For each emergent theme, I interpreted the associated accounts by means of the theoretical framework. Hence, I searched for evidence of Isaac’s participation in communities of practice, based on Wenger’s (1998) two components of identity: identification and negotiability. Making a longitudinal approach to the accounts, I further looked for changes in Isaac’s expressed identification and negotiability. I identified discontinuities by comparing labels across interviews, marking out repeated accounts of turning points and recognising changes in attitudes and expressed perspectives regarding mathematics practices. In the subsequent analysis, I focus on Isaac’s accounts belonging to the emergent theme *perspectives on mathematics and its role in mathematics teaching*. They provide evidence of identity development in terms of Isaac’s strengthened affiliation towards the practices of mathematics teacher education, yet, his struggles of realising his ambitions in own mathematics teaching.

## The case of Isaac

In Norway, two university teacher education programmes qualify for mathematics teaching in secondary school (grades 8-13): a five-year Master’s programme in mathematics and natural sciences including teacher education (1), and a one-year, post-graduate teacher education programme (PPU) (2). In both (1) and (2), the students undergo longer periods of school placement in lower and upper secondary school, and they take courses in general pedagogy and mathematics education. Isaac comes from the latter programme, building on a Bachelor’s degree in chemistry and about 60 ECTS credits in mathematics. I approached him to be a participant in the larger study based on his responses to a set of questions that was given to all last-year student teachers in mathematics belonging to either the five-year Master’s programme or the one-year PPU programme, within one Norwegian university. In

addition to reporting that he planned to work as a mathematics teacher after graduation, Isaac ticked off “agree” on the statements “I perceive myself as a teacher” and “I perceive myself as a mathematics teacher”. After graduating from PPU, Isaac took a temporary position as a mathematics and science teacher at an upper secondary school, teaching mathematics and science within both the general education programme and the vocational education programme Technical and Industrial Production. Two weeks into his new job, he looks back at PPU and describes it as a positive experience. Isaac elaborates on a changed view on teacher education with terms such as becoming part of the way of thinking and mastering the language of a new discipline.

Isaac: I’ve liked that kind of studies, actually, much more than I had thought that I would like it because I’m used to solving problems with two underlines underneath the answer, and it was more fun than I thought writing papers [laughing]. (...) it has motivated me to think now I’m going to change the math classroom (...). And I feel that I have a lot of commitment, many things I would like to do, because of things I’ve learned in for example the math education lessons.

Isaac: After the first semester (...), I didn’t yet get the hang of it, mastering the discipline and its format properly (...) didn’t get the message of what we were learning and doing, as well as I did in the second period. Because then I was part of the way of thinking, then I kind of felt I had an eye-opener about how to work with the discipline, how to understand the discipline. (...) I got into the literature, and suddenly understood what all these authors wanted to tell, I understood the language, the way of thinking.

Isaac portrays teacher education as something that has turned out as more interesting and enjoyable than expected. He elaborates on his changed view by describing a difference between the first and second semester at PPU, from not “get[ting] the hang of it” and not “get[ting] the message”, to understanding “the language, the way of expressing (...) and thinking”. He tells about having an eye-opener into the language and mind-set of the teacher education programme, where the lectures provided motivation for “chang[ing] the math classroom”. To make the change of his mathematics teaching possible, Isaac has signed up for an in-service course in order to try out inquiry based mathematics teaching in his own classroom and share his experience with the other participants.

Isaac: I signed up for a course (...), the topic is inquiry based teaching, I chose a math project, in which I will try to, to a greater extent, inquiry, landscape of investigation, and see how it works, and try to break the instinct of standing and chanting at the blackboard. (...) Then I have committed myself to it through this project (...) so it becomes binding.

However, in an interview conducted three months later into his first year of teaching, Isaac accounts for an experience of stagnation when trying to change his mathematics teaching according to his ambitions. He struggles to find the resources for developing new activities, both in terms of having enough time to implement it and to getting the good ideas for inquiry based mathematics activities.

Isaac: I run dry of ideas when I’m supposed to find out how they can make the sign charts inquiry based. I’ve tried, but it has been a lot harder than I expected, to find these

activities (...). Sometimes I've managed it (...) but not close to the amount that I wished for. I've done enough to meet the requirements of the in-service course, but I'm not able to do much more than that. I wanted a lot more. I have ambitions about doing more.

Instead of being a trigger for changing his teaching, the in-service course on inquiry based mathematics teaching has happened in parallel with Isaac's classroom teaching. Yet, he still holds on to his ambition of changing his teaching practice in the future. Despite having a "way to go to get the right tools for it", he imagines becoming a teacher who provides the students with a need to approach mathematics differently than seeking the one, correct answer on a series of tasks.

Isaac: I want to become the teacher who basically does two things. First of all, makes the students understand why, not knowing, but understanding, that's my first ambition, and the second ambition is to be the one who makes you eager for knowledge. The one who makes you wanting to know, wanting to understand (...) and to reach that, I think I have to change the teaching in a way that students don't get away with rattling off, or, they have to see the value in and the need of understanding. (...) I think I have a way to go to get the right tools for it.

In the final interview, taking place six months into his first year of teaching, Isaac voices a similar limited ability for establishing a different mathematics practice in the community of secondary mathematics teaching. Although he endeavours to invite the students into mathematics activities with no one, correct answer to the problems being posed, some of the students seem to hold on to their previous developed learning strategies. These students find comfort in solving textbook tasks with clear instructions, and they simultaneously avoid solving open problems that require a more flexible approach to the mathematics content. Isaac thus expresses lack of progress regarding his ambitions of teaching mathematics for understanding.

Isaac: What I've tried to do is not giving them access to the procedures so easily, meaning, the algorithms. I have tried to limit it, quite simply, the possibilities to memorise, not giving them any choice. And then tried to give them some open tasks, meaning, not a, b, c, d, which leads to something, but instead give them only d. But they don't succeed. I don't succeed, even if I try. If I only give them the task d, then I get kind of, resigned, almost tearful looks (...). Then I have to hold their hands the whole way, and I can never take off the support wheels.

The narrative analysis of Isaac's accounts displays a story of overcoming a discontinuity regarding mathematics, its teaching and learning, when undergoing teacher education. Looking back at the PPU programme, Isaac explicates differences between university mathematics with its "two underlines underneath the answer" and the imperfect and corrigible knowledge of the social sciences that were represented in teacher education. However, he also tells a story of expanding his perspectives on the practices of PPU, of changing his view on teacher education, its literature and modes of reasoning. His motivation for changing his mathematics teaching in line with what is communicated at PPU indicate thus an inbound movement within the practices of the teacher education programme. Due to his descriptions of having the need to change his teaching in direction of inquiry based mathematics

practices, Isaac's accounts further indicate inbound participation within a community of inquiry based mathematics teaching. He identifies with the community practices by exercising both engagement and imagination. The engagement involves signing up for an in-service course at his new school of employment, while imagination involves picturing himself as a future teacher who exercises mathematics teaching in line with what was communicated at PPU. However, Isaac also reports on a kind of conflict regarding the meaning of mathematics teaching and learning in the secondary mathematics classroom, which can be understood as the work of reconciling memberships across community boundaries (Akkerman & Bakker, 2011; Wenger, 1998). The reconciliation involves Isaac's continued identification with practices in the community of inquiry based mathematics teaching, his and his students' attempt of establishing a community of secondary mathematics teaching, as well as his students' former memberships in communities of mathematics teaching and learning in previous schooling. Isaac's attempt of establishing a meaning of mathematics teaching and learning in his secondary mathematics teaching is thus an issue of negotiability. Since the meanings that he and his students produce for mathematics are not only local and delimited by the classroom, different meanings compete for the definition of what mathematics teaching is or should be. Based on Isaac's accounts, the meanings of mathematics teaching and learning stemming from the students' previous mathematics practices seem to rule. He expresses limited ability to define what is appropriate regarding understanding in mathematics (understanding *why*, not only knowing what to do), with the consequence of being pulled away from his initial ambitions of exercising inquiry based teaching. Instead of establishing a new mathematics practice, the outcome is an ongoing conflict between him and the students regarding how mathematics should be taught and learned. Accordingly, Isaac gives descriptions of a limited ownership of meaning, in the form of undesired stagnation in his mathematics teaching practice.

## Discussion

I have reported on the participative experiences of one individual mathematics teacher during his first year in upper secondary school. The study is based on the assumption that teacher learning is more than coming to know content, skills and practices. Rather, prospective mathematics teachers are active participants, who negotiate their experiences and create images of themselves and their challenging tasks and dilemmas in mathematics teaching (Carter & Doyle, 1996). Similarly, Sfard and Prusak (2005) claim that "human beings are active agents who play decisive roles in determining the dynamics of social life and in shaping individual activities" (p. 15). Developing a teacher identity thus brings with it "a sense of agency, of empowerment to move ideas forward, to reach goals or even to transform the context" (Beauchamp & Thomas, 2009, p. 183) in which mathematics teaching takes place. Although agency is not a term used by Wenger (1998), his theorisation of identity as identification and negotiability has in this study provided a conceptual tool for gaining insight into Isaac's ability and legitimacy to contribute to and take responsibility for the meanings that matter regarding mathematics teaching and learning in a secondary mathematics classroom. The results display some inconsistency between, on the one hand, his increased identification with mathematics teaching through inquiry, and on the other hand, his sense of negotiability regarding inquiry based mathematics teaching in the classroom. Identification with reform-oriented practices of mathematics teaching and learning is an important first step towards change and development of mathematics

teachers' practices. However, in order to explain further the possibilities for Isaac to develop his identity as a mathematics teacher in terms of changes in his practice, negotiability has appeared in this study as an important construct. Based on his accounts, Isaac seems to exercise imagination in a community of inquiry based mathematics teaching, by picturing a changed mathematics teaching practice. Yet, the results suggest that further participation by engagement, including active negotiation with other actors of a reform-oriented enterprise, is needed in order to alter the economy of meaning, and thus, to enable Isaac to implement the desired changes into his classroom teaching.

# Students' abilities on the relationship between beliefs and practices

Safrudiannur<sup>1,2</sup> and Benjamin Rott<sup>2</sup>

*Most studies that deal with possible influences of the social context related to students' abilities on the connection between beliefs and practices involve only a small number of participants (e.g., 1 – 3 teachers). Thus, we have designed a new quantitative questionnaire (named TBTP) which is intended to examine these influences for a larger number of teachers (here: N = 43). Then, for a further qualitative investigation, we interviewed and observed lessons of three of those teachers. The results show that the 43 teachers distinguish their style of teaching in different contexts of students' abilities. The correlation between beliefs about mathematics and the styles of teaching can be seen in the context of low ability students rather than in the context of high ability students. In the further investigation, this correlation is supported by the three teachers' descriptions of their general teaching of mathematics and their real practices in classes containing many low ability students.*

*Keywords: Teachers' beliefs, teaching and learning of mathematics, students' abilities.*

## Introduction

Some researchers have shown that there is a connection between teachers' beliefs and practices (see Philipp, 2007). Other researchers, however, have reported that there may be inconsistencies between teachers' beliefs and their practices (Raymond, 1997; see Philipp, 2007). Buehl and Beck (2015) argue that such inconsistencies should not be a reason to discount the power of beliefs, but that other factors like social contexts support or hinder the connection between beliefs and practice. Several studies (e.g., Raymond, 1997; Cross Francis, 2015) have revealed that social contexts in a classroom might cause teachers to act in a way that differs from the way that fits their beliefs. However, most of the studies revealing the influence of social contexts are case studies involving only a small number of teachers such as one, two, or three teachers (see Raymond, 1997; Cross Francis, 2015).

Studying teachers' beliefs and practices by doing intensive case studies involving interviews and observations may provide convincing data (Philipp, 2007), but they are too expensive for large samples of teachers. The use of self-report instruments is cost-effective, but their accuracy and validity are criticized (e.g., Di Martino & Sabena, 2010). Most self-report instruments measuring beliefs use closed questions, mainly Likert scale items. However, Di Martino and Sabena (2010) question the use of the Likert scale since it amplifies problems related to social desirability. The social desirability problem may arise when items being rated are viewed as inherently positive by respondents (McCarthy & Shrum, 1997). Thus, teachers' responses to rating or Likert scale items may reflect what is socially accepted and should be done rather than what actually is done (Fang, 1996). Furthermore, Likert scale items provide less or no contexts (Philipp, 2007), whereas, as we pointed out before, social contexts at school may affect teachers' practices in a classroom.

We offer an approach to minimize the social desirability problem and consider the social contexts at school in order to increase the accuracy of the prediction of teachers' beliefs and practices. We have

developed a questionnaire for studying teachers' beliefs on their practice (named TBTP). We use rank-then-rate (a combination of ranking and rating) items. McCarthy and Shrum (1997) show that using rank-then-rate items may reduce respondents' tendency to give high ratings towards items viewed inherently positive socially. Moreover, we consider students' abilities as the social context in a classroom since several researchers (e.g., Raymond, 1997; Beswick, 2018) have shown that students' abilities may influence teachers' beliefs and practices.

We conduct this pilot study to evaluate whether the TBTP gives us insight into the relationship between beliefs and practices in different contexts of students' abilities. Ribeiro et al. (2019) suggest that considering beliefs and practices in diverse contexts may contribute for a better understanding on the beliefs and practices in order to improve the quality of teacher education.

## **Theoretical framework**

### **Beliefs of the nature of mathematics and its association with teaching and learning of math**

Philipp (2007, p. 259) defines "beliefs as psychologically held understandings, premises, or propositions about the world that are thought to be true". Teachers may hold various beliefs about mathematics since they may see mathematics with different views. Ernest (1989) summarizes three views about the nature of mathematics: *the instrumentalist view* (mathematics as an accumulation of facts and rules to be used in the pursuance of some external end), *the Platonist view* (mathematics as a static but unified body of knowledge), and *the problem-solving view* (mathematics as a dynamic process which is continually expanding field of human creation and invention). Nonetheless, Ernest (1989) argues that teachers may merge elements from more than one of the three views.

Ernest (1989) further argues that the three views about the nature of mathematics can be associated with the models of teaching mathematics: (1) the instrumentalist view is linked with the role as an instructor who demonstrates math skills correctly; (2) the Platonist view is linked with the role as an explainer who describes the relation of concepts; and (3) the problem-solving view is linked with the role as a facilitator who likes doing problem solving or posing activities.

### **Students' abilities as a social context**

Empirically, Ernest's association between beliefs about mathematics and teaching of mathematics has not been demonstrated well. Ernest (1989) argues that social contexts such as students' behaviors may cause inconsistencies between teachers' beliefs and practices. Raymond (1997) has shown that students' abilities, attitudes, and behaviors have strong influences on teachers' practice. Moreover, Zohar, Degani, and Vaaknin (2001) found that most teachers believe that teaching with higher order thinking is only appropriate for high-achieving students, not for low-achieving students. Therefore, in this study, we consider students' abilities as the social context which may affect teachers' practices.

## **Research questions and method**

As pointed out before, studies revealing the influence of the social context on teachers' practices involved only small numbers of teachers. In this study, we will examine the influence of the social context related to students' abilities for a larger number. The questions are: (1) How and why do teachers differentiate their style of teaching and learning of mathematics because of students' abilities? And (2) how do students' abilities influence the relationship between teachers' beliefs about

mathematics and their styles of teaching? To answer the questions, we use a multi-method design by combining the TBTP questionnaire with interviews and classroom observations.

**The TBTP.** This questionnaire has ten rank-then-rate items grouped into three themes presented in the Appendix (see Safrudiannur & Rott, 2018, for the evaluation of the reliability and validity of the TBTP). In this paper, since we focus on teaching of mathematics, we only discuss teachers' responses to items of Themes 1 and 3. Each item consists of three statements. The first, second, and third statement are always associated with the instrumentalist, the Platonist, and the problem-solving views, respectively. To consider students' abilities as the social context, the items of Theme 1 are posed twice: for classes dominated by high ability (HA) and by low ability (LA) students (see Figure 1). Please note that we define the terms HA and LA by using the students' achievements (see Appendix), following Zohar et al. (2001) who use the terms achievement and ability interchangeably.

Item 1: When you teach the formula in a class dominated by <b>HA students</b> , what is important for you?							Item 2: When you teach the formula in a class dominated by <b>LA students</b> , what is important for you?								
<b>RANK</b>							<b>RANK</b>								
Please order the three statements below by giving a rank 1 (the most important), 2, or 3 (the least important).							Please order the three statements.								
<b>Statements</b>						<b>Rank</b>	<b>Statements</b>						<b>Rank</b>		
R1. You demonstrate how to use the formula correctly by giving some examples.						3	Statement R1						2		
R2. You explain concepts related to how to get or to prove the formula.						2	Statement R2						1		
R3. You let your students discover the formulas in their own ways.						1	Statement R3						3		
<b>RATE BASED ON YOUR RANK ABOVE</b>							<b>RATE BASED ON YOUR RANK ABOVE</b>								
Please rate the level of importance of each statement based on your rank above.							Please rate the level of importance of each statement.								
<b>Statements</b>						<b>Rate</b>	<b>Statements</b>						<b>Rate</b>		
Statement R1	1		3	4	5	6	7	Statement R1	1	2	3	4	5	6	7
Statement R2	1	2	3		5	6	7	Statement R2	1	2	3	4	5	6	
Statement R3	1	2	3	4		6	7	Statement R3	1		3	4	5	6	7

**Figure 1: An example how Fitria responded to item 1 and item 2 (identical statements) of the TBTP**

To respond to an item, a respondent firstly orders the three statements of the item by assigning a rank 1, 2, or 3, and then rate each of them from 1 to 7 based on his ranks (see Figure 1). Thus, there will be two sets of data: ranking and rating data. For data analyses, we only use rating data, because ranking data is included. The purpose of the ranking part is only to make respondents discriminate three statements of each item before rating them and to minimize the impact of the social desirability.

We asked 43 Indonesian math teachers who accompanied their students in a math competition to respond to the TBTP (their background in detail, sex: 33 females, 7 males, and 3 did not state; school: 14 from primary, 16 from lower secondary, 10 from upper secondary, and 3 did not state; teaching years: 7 for less than two years, 10 in between two and five years, 9 in between five and ten years, 16 for more than ten years, and 1 did not state).

**Interviews and Observations.** Three (all from lower secondary) of the 43 teachers volunteered for a further investigation: Elisa (female), Fitria (female), and Dony (male). Elisa and Dony were math teachers for two to five years, and Fitria for more than ten years. We chose them since they could represent lessons in HA and LA classes. The interviews aimed at finding information about their beliefs about mathematics and general teaching of mathematics. We identified key words/ statements reflecting their beliefs. We also videotaped one lesson from each teacher. We used the coding system from the TIMSS Video Study 1999 to interpret the lessons. We categorized the interaction (*Public*,

*Mix, Private*) and the content activity (*Non-problem* or *Problem Segment*) of the lesson (we explain each term directly in the description of each lesson in the result section to save space). Both authors of this paper and one expert from Indonesia made the interpretation of interviews and lessons. The lowest percentage agreement is 70 % (we did discussions [consensual validation] to solve disagreements).

## Results

### Responses to the TBTP questionnaire

Tables 1 and 2 summarize the responses of all 43 teachers to the TBTP. The results of paired t-tests show that teachers significantly differ their reported styles of teaching between HA and LA classes. Table 1 shows that teachers gave higher rates to the statements associated with the instrumentalist view for LA classes than to those for HA classes. In contrast, the statements associated with the problem-solving view for LA classes have lower rates than those for HA classes.

No	Statements of Theme 1 (views associated with the statements)	Teachers (n=43)		t-values (df=42, two tailed)	Elisa		Fitria		Doni	
		HA class Mean (sd)	LA class Mean (sd)		H A	L A	H A	L A	H A	L A
1 and 2	R1 (Instrumentalist view)	4.09 (1.66)	5.65 (1.13)	-6.19 <sup>a</sup>	5	7	2	5	2	6
	R2 (Platonist view)	5.02 (1.39)	5.44 (1.42)	-1.46	6	5	4	7	4	4
	R3 (Problem-solving view)	5.33 (1.55)	3.47 (1.24)	6.35 <sup>a</sup>	4	4	5	2	6	2
3 and 4	S1 (Instrumentalist view)	4.07 (1.49)	5.35 (1.15)	-4.99 <sup>a</sup>	3	5	2	5	5	6
	S2 (Platonist view)	5.86 (1.19)	5.47 (1.32)	1.57	7	7	5	7	6	3
	S3 (Problem-solving view)	5.44 (1.05)	3.79 (1.81)	5.52 <sup>a</sup>	6	4	6	4	4	1

<sup>a</sup> significant for  $p < 0.004$  (The adjustment of  $\alpha = 0.05$  by Bonferroni's correction for 12 multiple t-test)

**Table 1: Teachers' responses to items of Theme 1 and the results of the paired sample t-test**

There are no differences between rates related to the statements regarding the Platonist view. This indicates that explanation and understanding for both HA and LA classes are essential to the teachers.

No	Statements of Theme 3 (views associated with the statements)	Teachers (n=43)	Correlations with statements of Theme 1 in the same view		Elisa	Fitri	Doni
		Mean (sd)	HA class	LA class			
9	P1 (Instrumentalist view)	5.37 (1.43)	R1 (0.29), S1 (0.39 <sup>b</sup> )	R1 (0.42 <sup>b</sup> ), S1 (0.34 <sup>a</sup> )	6	6	5
	P2 (Platonist view)	4.95 (1.19)	R2 (0.30 <sup>a</sup> ), S2 (0.28)	R2 (0.18), S2 (0.33 <sup>a</sup> )	5	5	3
	P3 (Problem-solving view)	4.70 (1.39)	R3 (0.28), S3 (0.26)	R3 (0.25), S3 (0.20)	4	4	2
10	Q1 (Instrumentalist view)	5.09 (1.54)	R1 (0.07), S1 (0.29)	R1 (0.44 <sup>b</sup> ), S1 (0.53 <sup>b</sup> )	5	6	6
	Q2 (Platonist view)	5.14 (1.49)	R2 (0.33 <sup>a</sup> ), S2 (0.36 <sup>a</sup> )	R2 (0.32 <sup>a</sup> ), S2 (0.39 <sup>b</sup> )	3	4	3
	Q3 (Problem solving view)	4.42 (1.26)	R3 (0.09), S3 (0.07)	R3 (0.53 <sup>b</sup> ), S3 (0.54 <sup>b</sup> )	4	3	5

<sup>a</sup> significant for  $p < 0.05$ ; <sup>b</sup> significant for  $p < 0.01$

**Table 2: Teachers' responses to items of Theme 3 and the results of the Pearson correlation**

Table 2 summarizes the responses of all 43 teachers' to the two items of Theme 3. Most of the teachers gave higher rates to statements associated with the instrumentalist view (P1 and Q1). Interestingly, the correlation analyses indicate that the rates to the statements of Theme 3 (about the nature of mathematics) significantly correlate to the rates to the statements of Theme 1 (about teaching and learning of mathematics) for LA classes, particularly in the instrumentalist view.

## Interviews

All three teachers' reports about their beliefs of the nature of mathematics seem to be in line with their responses to the items of Theme 3 of the TBTP presented in Table 2 (all gave higher rates to both statements P1 and Q1 associated with the instrumentalist view than to the other statements).

Elisa: I often meet people who love mathematics so much. I think, I am not like that. I am amazed by people who can (...) such as (...) can understand fast, and fast in solving problems or anything. I am not, honestly, I understand slowly. So, I think, math is a collection of facts, formulas, which make me confused.

Fitria also expressed that mathematics consists of a lot of formulas and rules which are useful for solving problems and their truth is absolute. Doni also expressed that the truth of mathematics is absolute since its contents result from absolute agreements which could not be changed. He stressed that mathematics is useful for humans for solving problems and that it can be applied universally. Additionally, all three interviewees emphasized the importance of memorizing math formulas for their students. These expressions seem to indicate that they dominantly hold the instrumentalist view since they view mathematics as a toolbox consisting of utilitarian facts and rules to be used by the skillfully trained artisan in the pursuance of some external end (Ernest, 1989).

All interviewees described that they usually taught mathematics by demonstrating formulas and giving examples (in line with their responses to items of Theme 1 for LA classes, see Table 1). They spent lots of time providing many examples and often repeated their explanation to ensure that students understood mathematics. They assessed that many of their students were LA students. They argued that if their classes were dominated by HA students, they would be able to apply their ideal teaching. They believed that only HA students could discover mathematical formulas by themselves.

Doni: Ideally, teaching in HA class. In my class, the abilities are heterogenous. I tend to... just did ordinary teaching. Giving them examples (...) cases (...) basic examples.

Unlike Elisa and Fitria who rarely met HA students, Doni reported that he had a club whose members were HA students from different classes. These students were trained to follow mathematics competitions. In the club, he gave his HA students difficult math tasks taken from math competitions.

## Observed Lessons

Elisa taught her students solving a geometry task in the videotaped lesson in her LA class. Before handing out the task, a non-problem (NP) segment (*a segment containing math information but no tasks/problems*) took place. The interaction during this NP segment was coded as Public (*a public dialogue conducted by the teacher and other students must listen to it*) since Elisa led students to recall some math formulas and concepts. Public interactions also dominated the interaction during the problem segment (PS, *a segment containing math tasks/problems*) since Elisa often asked her students questions to make them recall some math formulas which were useful to solve the task. If students did not recall formulas, she reminded them of the formulas. Moreover, Elisa demonstrated, slowly explained, and guided students on how to use the formulas in the observed lesson.

There was no NP segment in Fitria's lesson in her LA class. Fitria taught about the application of mathematical operation sets in the real world by giving four tasks. The interaction during the PS

segment of the first two tasks was only Public since Fitria demonstrated and explained the way to solve the two tasks. The interaction during the PS segment of the last two tasks was Private (*students individually worked on the two tasks*). However, during the Private interaction, Fitria reminded the students that they needed to refer to the way of solving the first two tasks, to be able to solve the last two. Moreover, when students got stuck, Fitria gave them mathematical clues to help them.

There was also no NP segment in Doni's lesson in his club (HA class). At the beginning of PS, Doni gave his HA students a sheet with 25 tasks. After that, he let students work individually (only Private interaction) without providing any clues to help them. After a break, Doni showed his students how to solve some of the tasks from the sheet, and the students checked their answers (Public interaction). During the show, Doni emphasized some math formulas that were important for students to memorize since the formulas were often used for solving tasks in mathematics competitions.

## Discussion and Conclusion

In this study, we examine the influence of social contexts related to students' abilities in a classroom on a large number of teachers (43 teachers). The results indicate that students' abilities have an impact on the link between teachers' beliefs about mathematics and the style of teaching mathematics.

Firstly, we found that the 43 teachers report significantly different styles of teaching mathematics between HA and LA classes (Table 1), indicating that students' abilities influence teachers' beliefs and practices (Beswick, 1998; Raymond, 1997). The responses to items of Theme 1 for LA classes show that most of the participants gave high rates to both statements (R1 and S1) associated with the instrumentalist view. Interestingly, they gave low rates to both statements (R3 and S3) associated with the problem-solving view. In contrast, they rated R3 and S3 for HA classes higher than they did for LA classes. The three teachers in the further investigation believed that only HA students could discover math formulas by themselves, whereas LA students would understand mathematics slowly and should memorize mathematical formulas. Without memorizing, LA students could not solve math tasks or problems in their opinions.

However, Table 1 also indicates that teachers do not distinguish their teaching styles related to the Platonist view. The average rates of R2 and S2 are high for both HA and LA classes. This indicates that explanation is an essential part of their teaching, and generally, teachers want their students, both HA and LA students, to understand what they teach (Van de Walle et al., 2013).

Secondly, we found that 43 teachers' rates to statements about the nature of mathematics (Theme 3) correlate with their rates to statements about teaching and learning of mathematics (Theme 1) for LA classes (see Table 2), particularly on the instrumentalist view. Our further analyses with the three teachers seem to support this correlation. Table 2 indicates that those three teachers' rates about teaching and learning of mathematics for LA classes reflect what they believed about mathematics. For example, Elisa and Fitria seemed to hold the instrumentalist view dominantly. Their high rates to R1 and S1 of the TBTP for LA classes (see Table 1) seem to reflect their instrumentalist view of mathematics. Further, their descriptions of their general teaching, as well as their actual practices, also indicate the influences of the instrumentalist views since they played a role as an instructor who demonstrates skills correctly (Ernest, 1989).

In contrast, the three teachers' responses to Theme 1 for HA classes (see Table 1) which seem to be in line with their ideal teaching may not reflect their beliefs about mathematics. Although they seemed to hold the instrumentalist view, they gave low rates to R1 or S1 associated with the instrumentalist view but high rates to R3 or S3 associated with the problem-solving view. However, we still can see the impact of the instrumentalist view from the responses; e.g., Doni's high rates to S1 indicate the significance of memorizing formulas for HA students. In the observed lesson, he emphasized that his HA students should be able to memorize some formulas. This fact confirms the indication.

There are some limitations in this study. First, all three teachers in the qualitative investigation dominantly hold the instrumentalist view. Second, the characteristics of tasks used in the TBTP may not cover the complexity of teaching mathematics. For example, the task of item 1 (or item 2) only provides three statements about lesson learning a formula in the geometry topic (see Appendix), whereas, the way how teachers give their lessons in their own classes may be more complex than those three statements. Therefore, since this study is our pilot study and we plan to continue this study with larger number of teachers, we are going to add rank-then-rate items from other math topics and open questions in the TBTP. Furthermore, in the qualitative investigation, we will involve teachers from other views of mathematics (besides the instrumentalist view) in order to have better insight into the influence of students' abilities on the relationship between beliefs and practices.

## Appendix

**General note:** As a mathematics teacher, you have experience with high and low ability students in mathematics. Consider these definitions:

*A high ability (HA) student is a student who generally shows a good understanding in your lessons and regularly has high scores in your tests.*

*A low ability (LA) student is a student who generally does not show a good understanding in your lessons and often has low scores in your tests.*

**Theme 1 (teaching and learning of mathematics):** You are going to teach a lesson learning the formula to calculate the area of a trapezoid. Please imagine this situation to answer the items 1 to 4.

**Items 1 and 2\*:** When you have the lesson in an HA/LA class, what do you think that is important for you?

R1. You demonstrate how to use the formula correctly by giving some examples (*the instrumentalist view*).

R2. You explain concepts related to how to get or to prove the formula (*the Platonist view*).

R3. You let your students discover the formula in their own ways (*the problem-solving view*).

**Items 3 and 4\*:** When you have the lesson in an HA/LA class, what do you think that is important for students?

S1. They memorize and use the formula correctly (*the instrumentalist view*).

S2. They understand the concepts underlying the formula from your explanation (*the Platonist view*).

S3. They can draw logical conclusions to deduce the formula (*the problem-solving view*).

**Theme 2 (teaching and learning of problem solving):** items 5-8, not discussed in this study.

**Theme 3 (the nature of mathematics):** Mathematics contents taught at school can be divided into several sub-domains such as numbers, algebra, geometry, measurements, statistics, and probability. The classifications of mathematics contents, in general, are more complicated, for example, classical algebra, linear algebra, number theory, differential geometry, calculus, statistics, probability theory, etc.

**Item 9:** In general, what do you think of the contents of mathematics?

P1. Mathematics is an accumulation of facts and skills, which are useful for human life. (*the instrumentalist view*)

P2. The contents are interrelated and connected within an organizational structure (*the Platonist view*).

P3. Mathematics is a dynamic process of human activities. The contents of mathematics expand and change to accommodate new developments (*the problem-solving view*).

**Item 10:** What do you think of the truth of the contents of mathematics?

Q1. The truth is absolute. The contents are free of ambiguity and conflicting interpretations (*the instrumentalist view*).

Q2. Mathematical ideas are pre-existing; humans just discover the contents of mathematics. Thus, the truth-value of mathematics is objective, not determined by humans (Q2, *the Platonist view*).

Q3. The contents are created by human and therefore, their truth-value is also established by humans (Q3, *prob. sol.*).

\* Items 1 = 2 and 3 = 4, but with different classes (1 and 3 for HA, 2 and 4 for LA classes). See Figure 1.

## Secondary school preservice teachers' references to the promotion of creativity in their master's degree final projects

Alicia Sánchez<sup>1</sup>, Vicenç Font<sup>1</sup> and Adriana Breda<sup>1</sup>

<sup>1</sup>University of Barcelona, Spain; [asanchezb@ub.edu](mailto:asanchezb@ub.edu), [vfont@ub.edu](mailto:vfont@ub.edu), [adriana.breda@gmail.com](mailto:adriana.breda@gmail.com)

*What do preservice teachers think about creativity and the ways to promote it in their classes? In this study, we analyze the references to creativity that appear in the master's degree final projects of a group of secondary school preservice teachers of mathematics. The projects hold the preservice teachers' reflections on their own practice, but it is important to note that the master's degree does not include any specific training in creativity. In our analysis, we first searched for explicit references to creativity in the projects and registered them. Then, we classified the comments depending on the elements of the teaching and learning process that are related to creativity in each case. We observe a good variety of comments and more than half of the preservice teachers mention creativity, although some of them just do it superficially.*

*Keywords: Preservice teachers, creativity, master's degree final project, didactic suitability.*

### Introduction

In recent years, creativity has become an important focus of interest of social sciences. Creativity could be related to the development of other abilities such as critical thinking, problem solving, communication and the use of new technology, current challenges in the globalized society (Pásztor, Molnár, & Csapó, 2015). In education, creativity has also gained importance and its development is a goal in modern curricula (Pásztor et al., 2015). In addition, many authors (Mann, 2006; Silver, 1997; Sriraman, 2005) claim that creativity should be fostered at school by inclusive activities, working with every student and not only with those considered gifted students. However, mathematics lessons at school are commonly associated with repetitive procedures and regardless of students' creativity.

Research on the promotion of students' creativity by improving the teachers' training (Hosseini & Watt, 2010; Panaoura & Panaoura, 2014) and research on teachers' conceptions of creativity (Lev-Zamir & Leikin, 2011) disregards the following question: how do the teachers consider the promotion of students' creativity in their learning sequences, when they do not receive specific training in this subject? In order to answer this question, in this study, we focus on how preservice teachers conceive the promotion of students' creativity when they analyze their own practice and propose some changes to improve it, in their master's degree final projects.

### Theoretical framework

There are several definitions and conceptualizations of creativity (Kampylis, & Valtanen, 2010; Kaufman, & Sternberg, 2006). Kaufman and Beghetto (2009) propose a model with different types of creativity: Big-C, which refers to eminent people whose creations have had an impact on a field; little-c, which is associated with everyday creativity which appears in daily activities; Pro-C, which is present in those professional activities that are generally considered specially creative; and mini-c, which they define as "the novel and personally meaningful interpretation of experiences, actions, and events" (Beghetto & Kaufman, 2007, p.73). Mini-c creativity is related to learning processes, since it

implies a personal interpretation of new facts based on previous experiences and knowledge. In our research, we consider the development of creativity at secondary school level, so we use the term in accordance with the definition of mini-c creativity.

Then, a question emerges: how is creativity generated in a teaching and learning process? Regarding this question, the first step is assuming that creative thinking is a complex process that can be studied as a process that emerges from others, as Malaspina and Font (2010) explained with the intuitive process. These authors propose that a method to investigate complex processes is decomposing them into more simple processes and they use the metaphor of the vector space: the more complex process, creative thinking in this case, can be understood as a linear combination of the basis vectors (other processes). This approach to creativity as a process emergent from other more simple processes, was also considered in the European project *A Computational Environment to Stimulate and Enhance Creative Designs for Mathematical Creativity (MC2)* (Sala, Font, Barquero, & Giménez, 2017):

Then, when we concluded that the way to conceptualize the creative process in mathematics is decomposing it into other processes, we considered, together with the MC2 team, that the best way to go further in its study was adopting the method proposed by the Ontosemiotic Approach [Malaspina & Font (2010)] ...but introducing an important variant. Instead of using a "basis" of processes defined a priori by the theoretical framework, we would use the "basis" that would be the result of a brainstorm performed by the participants in the project ...MC2 when each of them explained what they understood by "creative process".... As a consequence, the following aspects were revealed: a) When the members ...[participants in the project] aim at determining the criteria of design and assessment, they do not directly refer to the concept of CMT [Creative Mathematical Thinking], but they consider its decomposition into different dimensions, or processes, of mathematical activity, whose integration, through task design, [participants] think that would help to develop the CMT. b) There is a shared assumption that "the mathematical creative thinking will emerge from the interaction and integration" of these different dimensions or processes (p. 4–5).

On this line, in the master's degree final project -a document where the preservice teachers propose some changes to improve their own practice-, we could expect to find: 1) comments about creativity, since enhancing creativity is usually regarded as positive; and 2) in these comments, creativity would appear as a consequence of working other aspects that improve the instructional process.

Several studies on teachers' training suggest the reflection on the own practice as a key strategy to professional development and the improvement of instruction processes. On this line, the construct of didactic suitability of the Ontosemiotic Approach (Breda, Pino-Fan, & Font, 2017) has been used as a tool to structure the teachers' reflection in some teachers' training programs in Spain, Chile, Panama, Argentina and Ecuador (Breda, Font, & Lima, 2015).

The theory of didactic suitability originates from the need to have an instructional theory to help teachers to make decisions in designing, implementing and assessing their practice. Didactic suitability (Breda et al., 2017; Sullivan, Knott, & Yang, 2015) comprise six types of suitability. The epistemic suitability deals with the quality of the mathematics that are taught, and how the explained content is representative of the complexity of the mathematical object. The cognitive suitability is

about, on the one hand, the adequacy of students' previous knowledge for learning the intended content and, on the other hand, the relation between what students should learn a priori and what they have learnt indeed after the implementation. The mediational suitability has to do with the availability of time and material resources necessary in the teaching and learning process. The interactional suitability is the effectiveness of interactions (teacher-students or between students) to identify and solve conflicts of meaning and improve students' autonomy. The affective suitability refers to the students' involvement in the teaching and learning process. Finally, the ecological suitability is the adequacy of this process to the school's educational project, the curriculum and the social environment. In order to use these criteria as an assessment tool, some observable components and characteristics are associated with each criterion. They were used in the design of a practical rubric that can be found in Breda et al. (2017). As an example, we show the components and characteristics of epistemic suitability in Table 1.

Components	Characteristics
Errors	Practices considered mathematically incorrect are not observed.
Ambiguities	Ambiguities that could confuse students are not observed; definitions and procedures are clear and correctly expressed, and adapted to the target level of education; explanations, evidence and demonstrations are suitable for the target level of education, the use of metaphors is controlled, etc.
Diversity of processes	Relevant processes in mathematical activity (modelling, argumentation, problem solving, connections, etc.) are considered in the sequence of tasks.
Representation	<p>The partial meanings (constituted of definitions, properties, procedures, etc.), are representative samples of the complexity of the mathematical notion chosen to be taught as part of the curriculum.</p> <p>For one or more partial meanings, a representative sample of problems is provided.</p> <p>The use of different modes of expression (verbal, graphic, symbolic...), treatments and conversations amongst students are part of one or more of the constituents of partial sense.</p>

**Table 1: Components and characteristics of epistemic suitability (Breda et al., 2017, p. 1903).**

In our study, we distinguish which components of the different types of suitability preservice teachers relate to creativity in their comments, while they use the criteria to analyze their own practice.

## Context

The program of the master's degree in teaching in secondary school (specialization in Mathematics) includes a work placement in a secondary school divided into two periods. In the first period, that lasts two weeks, preservice teachers attend classes of their supervisors and know the group of students with which they will work later. The second period lasts six weeks, and the preservice teachers should implement a learning sequence that they have prepared. After the work placement, in the subject of

Innovation and research in Mathematics education, the didactic suitability criteria (Breda et al., 2017), with their components and characteristics, are introduced. Then, preservice teachers should use them in the analysis of the learning sequence that they implemented. The master's degree final project (MFP) includes this analysis and, based on it, the preservice teacher's proposal with some changes in the learning sequence that could help to improve the suitability of the teaching and learning process.

## Research questions and method

The aim of this study is to examine preservice teachers' ideas about promotion of students' creativity, while they analyze their own practice and justify some changes of the learning sequence to improve it, in their MFP. Preservice teachers do not receive any specific training in how to develop students' creativity during the master's degree. Our research questions are: 1) Do preservice teachers frequently include comments about the promotion of creativity in their MFP? 2) Which aspects of the teaching and learning process are related to the promotion of creativity in the preservice teachers' comments?

We considered the 198 MFP from the years between 2009-2010 and 2014-2015. First, we made a register with some information of each MFP (name of the preservice teacher, year, title of the learning sequence, level). We searched for explicit references to creativity or other words of the same word family (creative, creation, creator, create) in the MFP and made a second register with only those projects that include these comments (we used a reduced list of keywords in comparison with other studies, such as the one of Joklitschke, Rott and Schindler [2018]). Registered data of these MFP include the extracts with the explicit references to creativity, as shown in Table 2.

Then, we read the MFP with references to creativity and tried to find common patterns or characteristics in the comments in order to infer a classification of comments. Since the preservice teachers use the didactic suitability criteria to structure their analysis, we also used them to distinguish aspects that are associated with the promotion of creativity in the comments. It means that, in this first phase, we used the didactic suitability criteria as previous categorization to analyze the preservice teachers' discourse. Finally, in a second phase, we classified the comments into the different categories that we had formed inductively from the data.

For example, in the MFP of Fontalba (2014) we found two explicit references to creativity (shown in Table 2). In her analysis of the implemented learning sequence, the epistemic suitability is one of the worst valued. When she analyzes this suitability, she remarks that the learning sequence should include activities that enhance creativity (first extract in Table 2). Then, in the new proposal, she adds an activity in which the students have to create their own problems (second extract in Table 2). We consider that this comment is related to the diversity of processes (a component of the epistemic suitability) and, in particular, to the process of posing problems.

Title and year	Geometry in space. 2013 - 2014
Preservice teacher's name	F.D.
Level	3 <sup>rd</sup> course of Secondary School (14-15 years old)
Branch of mathematics	Geometry
References to creativity	Yes

Number of references	2
Extract	Diversity of processes. The mathematical quality of the learning sequence could be improved and one of the key components is the diversity of processes. The student should make, should learn through trial and error, manipulation, experimentation and exploration. There is an excess of algorithmic activities, to calculate and execute procedures, therefore activities that hold curiosity, creativity, imagination and discoveries should be included. (Fontalba, 2014, p. 4)
	Competence 4. Generating mathematical questions and posing problems. Clearly, this competence is developed since the goal of the contest is the creation and resolution of problems. (Fontalba, 2014, p. 11)
Comments	She refers to the development of creativity in the assessment of epistemic suitability, and she says that the diversity of processes should increase. Then, in the new proposal, there is a task in which the students have to create problems.

**Table 2: Example of the data of a MFP with some explicit references to creativity**

## Results

We found explicit references to creativity in 119 of the 198 MFP of the master's degree in teaching in secondary school from years between 2009-2010 and 2014-2015: in 2009-2010, 9 of 15 MFP include references to creativity; in 2010-2011, there are 16 out of 21 MFP; in 2011-2012, 20 out of 34; in 2012-2013, 14 out of 24; in 2013-2014, 25 out of 47; and in 2014-2015, 35 out of 57. In the MFP with references to creativity, we found different elements of the teaching and learning process associated with creativity. In the following lines, we describe the main categories that we distinguished and then we focus on one of them. The development of creativity is related to:

a) Tasks with notable processes (epistemic suitability). In some projects, the preservice teachers explain activities where students have to do some hypothesis, plan a resolution method, justify or put in practice other processes that are especially important while learning mathematics. In this category, we include those comments in which creativity is related to this type of activities. These preservice teachers expect to develop creativity using it to solve the activities. At the same time, epistemic suitability improves, since so does the diversity of processes, which is one of its components. 61 MFP include comments in this category.

b) The use of manipulatives and technology (mediational suitability). In this case, preservice teachers explain activities where students' creativity could be fostered by the use of computers and other material resources. Sometimes, preservice teachers do not refer to a mathematical creativity, but a plastic or artistic creativity that students practice in making a certain object that would be used in a mathematical activity later. 13 MFP include comments in this category.

c) The development of other skills that are useful in the current society (ecological suitability). In some MFP we found comments about a responsible use of creativity. Preservice teachers relate creativity to critical thinking or the development of the students' social competence. We associated these comments with the ecological suitability because they refer to some skills that are useful for living in society nowadays. 3 MFP include comments in this category.

d) Cooperative tasks (interactional suitability). In other MFP, preservice teachers explain activities in which cooperation between students plays a key role. Students' cooperation is necessary to solve the task and it would help to develop their creativity, while sharing their ideas in the resolution. 5 MFP include comments in this category.

e) The assessment procedures of the learning sequence (cognitive, interactional and affective suitability). In this category, we include the references to creativity that appear in the assessment criteria of the learning sequence or in the objectives of a certain activity that the preservice teacher proposes. Usually, in the corresponding MFP there are some changes in the assessment tools. For example, preservice teachers design new rubrics. They often oppose the traditional understanding of evaluation, proposing a competency based assessment and sharing the responsibility with the students through auto-evaluation and co-evaluation. These changes relate to several components: the learning, as a component of the cognitive suitability; the autonomy and the formative evaluation, as components of the interactional suitability; and attitudes and emotions, as components of the affective suitability. 18 MFP include comments in this category.

General comments. In some comments, we could not identify a clear connection between creativity and a particular element of the teaching and learning process, so we refer to them as general comments. In this category, there are references to the creative nature of the mathematical activity, references to the teachers' creativity when designing tasks to their students, and references to the role of creativity in the constructivism paradigm.

We observed that in 66 MFP there are more than one reference and, in some cases, several aspects of the learning sequence are related to the development of students' creativity. Most of the comments that are associated with a certain suitability criterion are in the category in which creativity is related to the diversity of processes. Therefore, we focused on this category, distinguishing different characteristics of the activities that the preservice teachers propose.

With regard to the comments in the first category, we found that in 14 MFP the development of students' creativity is associated with the resolution of problems, especially open-ended problems. Sometimes, creativity is specific to the phase of devising a plan to solve the problem. In 12 MFP, preservice teachers mention creativity when they ask the students to invent problems, think on significant contexts or create different representations. In 12 MFP, preservice teachers consider that the students' creativity can be fostered by working with real situations. 5 MFP include comments about developing creativity through project based learning. Five preservice teachers propose mathematical activities in the form of games that could enhance students' creativity. In the same category, there are some references to processes that preservice teachers relate to creativity: creation of arguments or justification (in 6 MFP), intra and interdisciplinary connections (in 5 MFP), creation of formulas and hypothesis (in 6 MFP), creation of mathematical models (in 5 MFP).

## Conclusions

Even when the preservice teachers do not receive a specific training in how to promote students' creativity during the master's degree, more than half of the MFP include references to creativity. First, we conclude that a significant number of preservice teachers in our sample implicitly consider that creativity can be developed in the mathematics lessons. There seems to be an implicit general agreement on the positive effect of the development of students' creativity on mathematics learning.

Second, preservice teachers' comments evidence that creativity is a complex topic and there are different ways to understand and promote it. We observe various elements or aspects of the teaching and learning process that are somehow related to the development of creativity in the preservice teachers' comments. Note that preservice teachers not only refer to mathematical creativity, their comments cover a wide view of creativity. Categories of the classification that we present here could change and evolve with the incorporation of new results from the analysis of the MFP of the following years of the master's degree. We conclude that preservice teachers consider that creativity is something that emerges from the interaction and integration of other aspects (especially different mathematical processes).

This study can contribute with results to other research on preservice teachers' education, showing evidence of the preservice teachers' perspective on creativity and its promotion in their learning sequences, when they do not receive any specific training in how to promote students' creativity. It could be interesting to observe how specific training in fostering students' creativity would affect the analysis that preservice teachers do in their MFP. We could also consider the possibility of using more keywords related to creativity to find comments in the MFP. As Joklitschke et al. (2018) explain, there are several conceptualizations of creativity and it is important to be aware that other words could be used to describe or conceptualize creativity. Then, we should consider other words that preservice teachers could use as synonyms of creativity. On the other hand, sometimes, the use of the word "creativity" does not seem to be relevant to the meaning of the whole comment or it is ambiguous (for instance, it is not clear whether it refers to teacher's or students' creativity). A possible solution would be revising the comments and rating their validity concerning their ambiguity.

*The identity  $0.999...=1$  connects to a variety of mathematical concepts and therefore allows for an investigation of teachers' school-related content knowledge (SRCK). This is a facet of their content knowledge (CK) that emphasizes links between school mathematics and the mathematics acquired in tertiary education. Some numerous reported misconceptions and potentially conflicting ideas on  $0.999...$  were presented to secondary school teachers in interviews. Especially in the case of conflicting ideas the relation between SRCK and teachers' reactions as part of their pedagogical content knowledge (PCK) was examined. The results showed that SRCK, as well as CK in general, is a prerequisite to successfully applying PCK. Further they lead to a discussion of the SRCK model's use in qualitative research.*

*Keywords: Qualitative research, Mathematics teachers, Secondary school mathematics, SRCK, Misconceptions*

## Introduction

Many research projects throughout the last four decades have shown that  $0.999...<1$  is a common misconception among students from secondary school and university, especially among pre-service mathematics teachers. Studies report that between a quarter and half of pre-service mathematics teachers agree that  $0.999...<1$  (Bauer, 2011; Buchholtz et al., 2012). Even among those who choose  $0.999...=1$ , only a minority is able to give appropriate reasons. Among German pre-service mathematics teachers, the most common argument for equality refers to a rounding process (Buchholtz et al., 2012). According to Bauer (2011), there seems to be no difference between high school students' and pre-service teachers' answers, and Yopp, Burroughs and Lindaman (2011) suggest that this robust misconception is found among primary level in-service teachers as well.

Nevertheless, there is a need for teachers to deal with  $0.999...$ : In the federal state of Lower Saxony (Germany) the local curriculum explicitly requires that high school students after grade 10 "explicate the equality  $0.999...=1$  as a result of an infinite process" (Niedersächsisches Kultusministerium [NK], 2015, p. 26, translated by the authors). Answering questions on  $0.999...$  requires well-founded knowledge of its nature. The mathematical background links to notions of infinity, convergence of series and the non-uniqueness of decimal representations. The concept of school-related content knowledge (SRCK), recently introduced by Dreher, Lindmeier, Heinze, and Niemand (2018), emphasizes such links between less formal school mathematics and formal academic mathematics.

Throughout this paper, we will focus on teachers' SRCK regarding the identity  $0.999...=1$  and their reactions to students' erroneous comments. In line with Yopp et al. (2011), Buchholtz et al. fear that

the academic knowledge in this field [0.999..., authors' remark] is not active, and so no substantial link between university and school mathematics can be made. (Buchholtz et al., 2012, p.116)

In that case, the high potential of cognitive conflicts that is intrinsic in this identity could be left unused: Teachers' deep understanding of the topic is necessary for successful teaching towards conceptual changes (Scott, Asoko, & Driver, 1991; Tall & Vinner, 1981). If it is missing, "teachers have the potential of undermining student understanding of important concepts" (Yopp et al., 2011, p. 313). To our knowledge, there is neither a study addressing in-service secondary school teachers' understanding of 0.999... nor addressing their teaching practices regarding that topic. This paper tries to step into the gap by an explorative interview study with eight in-service mathematics teachers from secondary schools.

## Theoretical background

Recently, Dreher et al. (2018) conceptualized problems around the old question of which knowledge is necessary for teachers with a new model of teacher knowledge emphasizing links between school mathematics and related university concepts. Their model refines Shulman's taxonomy as sketched in Figure 1. Dreher et al. (2018) split content knowledge (CK) into formal academic mathematics and more intuitive school mathematics.

In the German context, those two areas are linked by the secondary schools' curriculum, in which "fundamental ideas" (Dreher et al., 2018, p. 326; Kuntze et al., 2011) represent the structure of academic mathematics in school. They organize the curriculum's content and are revised by the students throughout the grades in a spiraled structure: Under the idea of "Numbers", Number systems develop from natural (grade 4) to nonnegative rational (grade 6) to rational (grade 8) to real numbers (grade 10). "Functions" start in verbal descriptions of dependencies (grade 6) and continue over tabular, graphical and formal descriptions of simple functions (grade 8) to more and more complicated ones (NK, 2015).

**Figure 1: Model of secondary school teachers' knowledge (inspired by Dreher et al., 2018, p. 330)**

In addition to curricular links between mathematics at school and in academics, Dreher et al. (2018) consider top-down relations – for example, during lesson planning, when teachers break down their academic knowledge to school level – and bottom-up relations that e.g. link students' "creative questions and answers" (Dreher et al., 2018, p. 328) to underlying mathematical concepts. Basing the links in teaching situations and the curriculum, the SRCK model is strongly related to the classroom. The representation of academic mathematics in the curriculum leads us to understand curricular knowledge as part of SRCK.

Dreher et al. (2018) assessed SRCK using a questionnaire and showed that the concept is empirically separable from general CK and from PCK. Yet they left it open to identify cognitive processes of SRCK as well as how to identify them in qualitative ways. As we will see, the identity  $0.999...=1$  inherits a broad variety of connections to academic mathematics. Therefore, analyzing the mathematics in teachers' reactions to students' responses on this topic seems a suitable way to observe SRCK. As students' erroneous statements are clearly part of PCK (Chick & Baker, 2005), this approach needs to separate knowledge about misconceptions from knowledge about the mathematics behind. We think that this is possible and, even more so, that the reactions to misconceptions linked to big ideas of mathematics reveal both SRCK and PCK and allow insight into their connections (Kuntze et al., 2011). So far, it seems that on the one hand the width and depth of CK predetermine how teachers implement their PCK in the classroom. On the other hand, without PCK, CK cannot be applied at all (Baumert & Kunter, 2013).

### **The identity of $0.999...=1$ in academic mathematics and school mathematics**

The mathematical symbol  $0.999...$  has a variety of meanings: It is a recurring decimal number as well as a sequence of finite decimals or of partial sums (in the dynamic sense of Weigand (2016)) or the limit of this sequence (in the static sense of Weigand (2016)) and a geometric series. These meanings cannot be clearly separated and may occur simultaneously (Bauer, 2011).

In school,  $0.999...$  is first met when working on decimal representations for fractions, which is one of the early experiences of infinity (Gardiner, 1985). Generalizing procedures like subtracting from finite decimals to their infinite counterparts at this stage happens unquestioned and is often used to show that  $0.999...=1$  (Bauer, 2011; Eisenmann, 2008). Yet Eisenmann (2008) points out that, for secondary school students, the decimal  $0.999...$  is very different from  $0.111...$  in its nature, as the latter one appears as a result of the (illegitimate but widely spread) written division algorithm for  $1:9$ . Never may  $0.999...$  be constructed as a result of  $1:1$ ,  $2:2$  etc., which might cause the doubts about  $0.999...=1$ , as reported in the introduction. Other reasons for the widely spread misconception that  $0.999...<1$  might be found in the language of limits, where terms like “approach” mislead to “but never reaches”, or in the understanding of decimal expansions, including the representation's non-uniqueness (Tall & Vinner, 1981; Weller, Arnon, Dubinsky, 2009).

In academic mathematics, the interpretation of  $0.999...$  as the limit of a geometric series is the most present one (Buchholtz et al., 2012). Thus, the question why  $0.999...=1$  is related to the topology of the real numbers and in nonstandard analysis is no longer true (Richman, 1999). In standard analysis, proving  $0.999...=1$  requires an understanding of converging sequences and series, including links to the big idea of “dealing with infinity” (Kuntze et al., 2011).

### **Teachers' reactions to cognitive conflicts**

Secondary school students might know from the introduction of decimal numbers in grade 6 that  $0.999...=1$ . This can later contrast their concept image of convergence of the series  $0.999...$  towards 1, as it is reported in some students' answers in Bauer (2011):

Mathematically it is 1, nevertheless I think there is always something remaining, even if it is however small. (Bauer, 2011, p. 90, translated by the authors)

Here, the student openly presents what Tall and Vinner (1981) call “potential conflict factors”: His concept image does not allow a limit to be actually reached, which leads to  $0.999... < 1$  (Tall & Vinner, 1981). This is closely related to a dynamic limit concept emphasizing potential and neglecting actual infinity (Weigand, 2016). Yet the student knows and states the mathematically correct answer. Though it cannot be seen from the quote whether he feels the conflict and a need to settle it, the potential for a cognitive conflict is evident. Despite a number of publications on how to evoke cognitive conflicts in the classroom, much less seems to be known on how teachers can help their students overcome them (Scott et al., 1991).

## Research questions and study design

The large number of possible connections from  $0.999...$  to academic mathematics and the lack of knowledge about teachers’ reactions to cognitive conflicts leads to three research questions: How do secondary school teachers react when students bring up misconceptions or potentially conflicting factors concerning the identity  $0.999...=1$ ? How do they refer to academic mathematics in their answers? And how do the reactions and the academic knowledge shown relate to each other?

In this explorative study, we report on interviews with eight teachers from different secondary schools in Lower Saxony. According to the curriculum (NK, 2015, pp. 26 and 58), all participants were expected to have experience in teaching  $0.999...=1$ . The interviews were conducted in an eased situation without any time pressure. First the teachers were asked about their contact with the topic in school. Then student’s response A (see Figure 2, responses taken from Bauer (2011)) was handed out in printed form. The participants were asked to comment on it and to explain how they would react. Then student’s response B – containing potential conflict factors as the quote above – was treated the same way. Finally, the teachers were asked to comment on a quote by Gardiner (1985; see Figure 2), especially on difficulties in putting his suggestion into practice.

<p>Instead of <math>0.99999...</math> (and so forth) we also write <math>0.\bar{9}</math>. Which of the following statements is true? Tick and give a reason.</p> <p><input type="checkbox"/> <math>0.\bar{9} &lt; 1</math>  <input type="checkbox"/> <math>0.\bar{9} = 1</math>  <input type="checkbox"/> <math>0.\bar{9} &gt; 1</math></p>	<p>Student's response A:</p> <p><math>0.\bar{9}</math> is unimaginably close to 1, but never reaches 1</p>	<p>Student's response B:</p> <p>Mathematically, <math>0.\bar{9} = 9/9 = 1</math>. But as you can put infinitely many digits of 9 behind, this number is always smaller than 1.</p>	<p>Quotation from Gardiner (1985), University of Warwick:</p> <p>No sensitive teacher would try to banish such ideas [misconceptions]: they are the raw material on which we must build.</p>
------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Figure 2: Material given to the teachers (translated by the authors unless originally English)**

The interviews were recorded, fully transcribed and analyzed using an inductive qualitative content analysis (Mayring, 2015). The transcripts were coded openly in two separate rounds: first for any eye-catching differences and for teachers’ reactions, second with focus on SRCK. In both rounds, the relevant teachers’ phrases were paraphrased in a common linguistic style. Then the paraphrases were shortened and rewritten more abstractly to receive possible categories. Those were unified and reduced to the most important categories, which were finally sorted into dimensions. In both rounds, coding manuals were written and given to an independent analyzer who recoded all transcripts. In cases of diverging ratings, consensus was reached. If necessary, examples were added to the manual or categories were renamed carefully.

## Results

Tables 1-3 show most of the categories found in the material in the left column. On the right, they provide the results of the rating. Dimensions are written in bold text, categories normally.

### Teachers' SRCK on 0.999...

From the broad range of links to academic mathematics, only a few were actually made by the teachers. All of them understood  $0.999\dots$  as a limit process in the dynamic sense. Only two teachers showed understanding of a static limit concept as well. Surprisingly, no teacher referred to a geometric series. Probably they had in mind that series are not taught in Lower Saxony schools.

**Table 1: SRCK dimensions shown by the teachers**

	T1	T2	T3	T4	T5	T6	T7	T8	
<b>Nature of 0.999...</b>									
is an object different from 1				X	X			X	
is a different representation for the same number as 1	X						X	X	← academic mathematics
is a dynamic limit	X	X	X	X	X	X	X	X	
is a static limit	X					X			← academic mathematics
<b>The identity <math>0.999\dots=1</math></b>									
knows proof(s) for the identity	X		X	X			X	X	
understands the presented proof	X	X		X		X	X	X	
doubts the presented proof			X		X			X	
... is a definition								X	
... is the result of a rounding process					X		X		
... does not hold					X				

One teacher denied that  $0.999\dots=1$  and one read the equality as a definition. Both of them saw no need in spending much time on the students' responses. Further, two teachers referred to rounding. Five teachers knew a proof for  $0.999\dots=1$ , four of them using  $0.999\dots=9/9=1$  or  $0.999\dots=3/3=1$  and one subtracting  $0.999\dots$  from 1. All of them applied techniques from finite decimal representations to infinite ones without justification. Three teachers doubted student B's claim that  $0.999\dots=9/9$ , though two of them claimed that  $0.999\dots=3/3$ . Teacher T8 later accepted the equality.

### Reactions to the students' responses

	T1	T2	T3	T4	T5	T6	T7	T8
<b>Dealing with student A's answer</b>								
link to underlying concepts			X	X				
arithmetical proofs	X	X	X	X		X	X	
correcting the fact		X					X	X
ignore							X	X
no specific reaction mentioned					X		X	X
<b>Dealing with student B's answer</b>								
link to underlying concepts	X		X			X	X	
arithmetical proofs		X		X		X		
no specific reaction mentioned					X			X

**Table 2: Teachers' reactions to both students' answers (shortened by non occurring)**

Inductively, we found five categories of teachers' reactions that applied to reactions on both students' responses. Most of the teachers responded to student's response A by showing an arithmetical proof for  $0.999\dots=1$ . Only two teachers went beyond by stressing notions of infinity or the static limit concept. Three pointed out the importance of correcting the student so that he would not memorize something wrong. The fourth reaction was to ignore, which two of the teachers intended. Teacher T7 named a broad variety of strategies depending on the students' grade.

As we comment on the teachers' reactions to student's response B, it should be noted that not all teachers noticed the conflicting factors in it (see Table 3). Only two teachers clearly named them. Both reacted by stressing the decimal representations' non-uniqueness; especially, they changed their approach compared to how they dealt with response A.

	T1	T2	T3	T4	T5	T6	T7	T8
Contact with $0.999...=1$ in school	sometimes	never	often	often	sometimes	rarely	-	rarely
Noticed the potential conflict factors	fully	no	no	partially	no	partially	fully	partially

**Table 3: Further four dimensions in teachers' responses**

Three teachers felt some conflict in the student's text but could not make sense of it. Some claimed that the student B had already disproved himself. Two of them (and another teacher who did not see any conflict at all) indicated that stressing the proof again should convince the student that  $0.999...=1$ . One wanted to use the proof to focus on a static limit concept, thus falling into both categories *link to underlying concepts* and *arithmetical proof*. Another link was made to the notion of infinity.

## Discussion

Regarding to our first two research questions, we need to conclude: Even though the topic of  $0.999...$  offers many possible links to academic knowledge, only the two concepts of non-unique representation and static limits were actually, and rarely, named by this study's participants. Further, several teachers' answers showed inconsistencies in their SRCK: One teacher claimed that  $0.999...$  and 1 are two representations for the same number and nevertheless referred to the process as rounding. Some claimed that  $0.999...=3/3$  but would not equal  $9/9$ . This strengthens our doubts about the teachers' access to academic mathematical knowledge, though all successfully finished at least two semesters of advanced mathematics at university. It especially raises the question on how to teach those links between school and academic mathematics to (pre- and in-service) teachers. An example of model-based task design for teacher education is given in Montes, Climent, Carillo, and Contreras (2019) in these proceedings; adopting this approach to the SRCK-model seems fruitful for both evaluating the task design process and improving teacher education programs.

In general, the teachers tend to respond to the misconception  $0.999...<1$  by showing an arithmetic proof. Some of them believed so much in the convincing power of proofs that they reacted to student B by restating and emphasizing the proof the student had already given. Only two participants fully recognized the potential conflict in student's response B; their common way of reacting was to establish a link to the decimal representations' non-uniqueness.

### Linking SRCK to the teachers' reactions

Except for T8, all teachers who showed at least one link to academic mathematics in their SRCK chose to talk about underlying concepts when confronted with the conflicting factors. This suggests that SRCK provides a most convenient way to react to cognitive conflicts, and thereby – as already known for CK in general – is a preliminary to successfully applying PCK (Baumert & Kunter, 2013). Yet in T3, we found a teacher who focused on the very general topic of (actual) infinity, thus establishing a link to one of the big ideas in mathematics (Kuntze et al., 2011) without showing much academic knowledge on  $0.999...=1$ .

Teachers who have more contact with the topic 0.999... in school more often relate it to underlying concepts. Whether experience mediates between SRCK and the reactions shown (Yopp et al., 2011) or whether teachers with higher SRCK spend more time and effort on 0.999... and thus gain more experience, cannot be answered from the data. Similarly, fully noticing the cognitive conflict seems to be linked to an approach of relating to underlying concepts as well as linked to high SRCK.

### Using the SRCK model in qualitative research

In our study, we used the SRCK model and qualitative content analysis to create detailed, comparable insight into teachers' knowledge. Yet the identity  $0.999...=1$  reveals boundaries of the distinction between academic and school mathematics: NK (2015) requires understanding limit processes without ever mentioning infinity. So does understanding infinity belong mainly to school or to academic mathematics? In the first case, the reactions of T3 that linked to this notion could form a new category *horizontal links within school mathematics*, whereas the other links are *vertical links to academic concepts*. This distinction would also foster independence of the curricular – hence cultural – background of our study: All mathematical links could be recorded before splitting them into horizontal and vertical ones depending on the local curriculum. This opens the door to an international curriculum-sensitive, yet comparable approach to SRCK.

Inductively developing dimensions brought to light some aspects of beliefs, for example, on the functions and nature of proofs. In subsequent studies, a multilayer model of teachers' knowledge including convictions – as suggested by Kuntze et al. (2011) – should be taken into account. Furthermore, studies like ours may help understand which of the many possible links from the curricular content to underlying concepts are a substantial part of SRCK in teachers' opinions.

The dimensions and categories developed for teachers' reactions allowed a clear distinction with broad consensus among all analyzers. In studies of a larger sample, they should be refined; especially, questions on their impact on students' learning and on their adequacy throughout different school grades arise.

# **“In school you notice the performance gap and how different it is between the students” – Student teachers’ collective orientations about the learners’ heterogeneity in mathematics**

Ann-Kristin Tewes<sup>1</sup>, Elisa Bitterlich<sup>1</sup>, Judith Jung<sup>1</sup>

<sup>1</sup>Technical University Dresden, Germany, [ann-kristin.tewes@tu-dresden.de](mailto:ann-kristin.tewes@tu-dresden.de)

*Collective orientations about the heterogeneity of the learners emerge on the basis of experiences that are unique to the individual, but in many ways structurally similar. Guided by the assumption that collective orientations significantly influence the practice of (student) teachers, our goal is to reconstruct (student) teachers’ ways of thinking in the context of heterogeneous learning groups in mathematics education using the documentary method. In the data of the project HeLeA<sup>1</sup>, it became apparent that one main focus of the group discussions was the variety of student performance. The differences in the achievement of the students, especially in mathematics, seem to be a great challenge for student teachers. Furthermore, there are discontinuities between the everyday discourse of student teachers and the academic discourse on the topic of heterogeneity.*

*Keywords: Heterogeneity, group discussion, teacher beliefs, collective orientation, teacher education.*

## **Introduction**

Heterogeneity is a central term of current debates regarding education and school system in Germany. In the educational context, it is associated with various categories of difference such as language, culture, gender or (dis)ability, and it is perceived to express “difference as a challenge to be dealt with actively” (Sliwka, 2010, p. 213). In Germany, discussions on heterogeneity in classrooms have recently been stimulated by educational policies like the ratification of the UN Convention on the Rights of Persons with Disabilities and social and demographic changes, e.g. increased linguistic-cultural differences because of a higher number of children with an immigrant background (Decristan et al., 2017). Due to changes in the main areas of attention – which are mostly oriented towards current political and social debates – different facets of heterogeneity and difference have been at the centre of focus (for some periods) lately. The impetus for a renewed focus on heterogeneity in Germany has been provided by the results of international comparison studies – in particular PISA, 2000/2009 (Klieme et al., 2010) – which have highlighted especially the sizeable differentiation in student achievement, the alarmingly high number of very low-achieving pupils, and a close relationship between social background and academic success (Döbert et al., 2004; Trautmann & Wischer, 2011).

---

<sup>1</sup> “Heterogeneity in teacher education from the start” (Heterogenität in der Lehrerbildung von Anfang an – HeLeA) is a sub-project of “TUD-SYLBBER” which is part of the “Qualitätsoffensive Lehrerbildung”, a joint initiative of the Federal Government and the Länder which aims to improve the quality of teacher training. The programme is funded by the Federal Ministry of Education and Research. The authors are responsible for the content of this publication.

The HeLeA project addresses this central debate about heterogeneity. The main assumptions of the project are that teachers' and student teachers' orientations, knowledge and attitudes play an important role in creating effective learning environments for all learners and in the development of an inclusive school that considers the learners' heterogeneity as something positive and normal (Booth, 2011; Reynolds, 2001). The quality of education depends to a high degree on the teaching staff, who play a key role in preparing their learners to take their place in society (Savolainen, 2009). Through qualitative (group discussion) and quantitative methods (questionnaire), the project aims at the reconstruction of student teachers' ways of thinking, speaking and feeling concerning the heterogeneity of learners in school, especially in mathematics. On the basis of the survey results, the project intends to design concepts for the education of student teachers in order to sensitize them to different facets of heterogeneity. The goal is to prepare them for encountering heterogeneity among their prospective pupils and to equip them with approaches for dealing with it in mathematics and also other school subjects. In this article, the focus is on the qualitative approach from HeLeA, as it provides interesting and emotional insights into the current state of teachers' opinions. Based on group discussions with high school mathematics students, the focus of this paper is on: "What collective orientations about the learners' heterogeneity in mathematics do student teachers have?"

## Theoretical background

The pedagogical discourse indicates multiple unresolved problems, and there is some criticism of previous approaches dealing with heterogeneity in school, like the homogenisation of learning groups through selection and forms of external differentiation (Trautmann & Wischer, 2011). At the same time, however, there is no lack of existing ideas and concepts for improving these approaches. Didactic-methodological concepts for internal differentiation have been discussed since the 1970s (Sliwka, 2010; Trautmann & Wischer, 2011). Strikingly, however, for most student and practising teachers the question of how to deal with heterogeneity nevertheless represents an important problem area in planning and teaching lessons. Schönknecht and de Boer (2008) point out that in describing heterogeneity, student teachers often seem influenced by polarisations and dichotomisations, as well as a limited perspective focusing on supposed "problem children". Many studies emphasise the individual and personal views of teachers and student teachers about heterogeneity (cf. Bitterlich & Jung, 2019). Most of these studies focus on teachers' beliefs and stereotypes<sup>2</sup> (Winheller, Müller, Hüpping, Rendtorff & Büker, 2012; Zobrist 2012). We focus on student teachers' collectively shared orientations concerning the learners' heterogeneity. In contrast to studies about teachers' and student teachers' beliefs and stereotype-threat, studies about collective orientations reconstruct those experiences and types of knowledge that can be considered as shared within the group of teachers. In this regard, collective orientations could be seen as "socially-agreed-upon knowledge base [...]. The

---

<sup>2</sup> Following Allport (1954), stereotypes – "the pictures in our head" – simplify our thinking and produce expectations about what other people are like and how they are likely to behave. In this sense, based on prior information (e.g. a student's test scores, social class, gender, ethnicity, race) a teacher develops expectations about the ability of the learner. Similar to this, beliefs are representative bits of information that a person has about an object, person or group of individuals based on certain facts or personal opinions (Ajzen & Fishbein, 1980).

key assumption behind them is that the members of the respective groups share a more or less common experience of enculturation into these groups” (Gellert, 2008).

Following Mannheim (1982), teachers tend to have the same or similar experiences and opinions because they belong to a ‘conjunctive space of experience’ (*konjunktiver Erfahrungsraum*).

Those who have biographic experience in common, have commonalities in their history of socialization and, thus, have a common or conjunctive experiential space, understand each other immediately insofar as these biographical commonalities become relevant in interaction and discourse. (Bohnsack, 2010, p. 105)

Teachers as well as student teachers represent a professional group whose conjunctive experiences materialise, on the one hand, via practical experience and, on the other hand, via conceptual-theoretical involvement with teaching and the didactic handling of heterogeneity (Sturm, 2012). The interweaving, or double structure, of their conceptual-theoretical conjunctive space of experience based on their own practical experiences, allows their participation in the social practice of teaching, and indeed creates it (Bohnsack, 2017).

In this context, Gellert (2008) emphasises that teaching should be perceived as a cultural practice that takes place in communities rather than an individual and independent practice that takes place in isolation behind closed classroom doors. In his findings, he emphasizes that the mathematics primary school teachers’ collective orientations about their own professional development sometimes work as obstacles against development. “Mutual validation can turn experience into law. [...] Collective teaching experience can be blind to alternative conceptions of teaching” (Gellert, 2008). Schieferdecker (2016) carried out group discussions with several groups of teachers about heterogeneity in society. The focus of his research is on the reconstruction of collective orientation patterns of teachers that can contribute to a broader understanding of the perception and management of heterogeneity in the educational practice of teachers. In this regard, the aim is to identify structures (which he assumes to be collectively shared) that teachers use in order to cope with the notions of social heterogeneity and heterogeneity in pedagogical practice. He reconstructs a tension between the conception of feasibility and the experience of powerlessness. On the one hand, teachers see themselves as solely responsible for the learning success of their students. On the other hand, they fail to ‘pick up every student where he or she stands’. But the reasons for their failure are suspected outside school (e.g. with parents). Even experienced teachers tend to see learners’ heterogeneity as a problem of increasing complexity which complicates successful teaching processes. To handle learners’ heterogeneity, teachers – and this is something that is collectively shared – homogenise them and create polarisations (e.g. high- and low-achieving learners) (Schieferdecker, 2016).

The aim of this paper is to reconstruct the collective orientations of student teachers in relation to mathematics. The performance heterogeneity<sup>3</sup> of the students is of great importance in Germany, as the school system aims for homogenisation (Trautmann & Wischer, 2011). We therefore believe that

---

<sup>3</sup> Helmke and Weinert (1997) point out, that in addition to subject-related and teaching aspects, the individual characteristics of the pupils, e.g. language, intelligence and learning strategies are of great relevance to the students’ performance (Helmke & Weinert, 1997).

the factor of performance differences in mathematics is particularly important to student teachers when talking about their experience in teaching math and when reflecting their own teacher education. We suspect that in a subject such as mathematics, the differences in performance become particularly clear. In this context, Thompson (1992) describes that American teachers consider mathematics as something static that contains a set of rules and procedures. To teach mathematics and to get a correct result, these have to be used, no matter if they have been understood. Since mathematics is often considered as a subject with ‘clear answers’, formal procedures and easily comparable results, student teachers might hold the (collective) orientation that especially in mathematics differences in achievement are more noticeable and with a higher weight than, e.g., in language-based subjects where different opportunities exist to express something or to write an essay.

## Methodology and procedures

One way to access collective and action-leading orientations of prospective teachers is through group discussions (e.g. Przyborski & Wohlrab-Sahr, 2014). Group discussions can help to identify and analyse the implicit or tacit knowledge of the participants while they talk about a specific topic (e.g. heterogeneity). The self-dynamic of the discussion process, without any interruptions by the researcher, is important to discover conjunctive spaces of experience, which become visible through ‘focusing metaphors’ in which the group adjusts itself to those specific topics that are most relevant in its members’ common experience (Bohnsack, 2010).

Concerning group discussions, the immanent meaning comprises that stock of knowledge which is made explicit by the participants themselves. This has to be distinguished from knowledge of experience, which is so much taken for granted by the participants that it must not and often cannot be made explicit by themselves. The participants understand each other because they hold common knowledge without any need to explicate it for each other. (Bohnsack, 2010, p.103)

The documentary method is a suitable method to analyse data from group discussions to identify and reconstruct collective experiences and common (used) ways of acting (Weller & Malheiros da Silva, 2011). In the identification, description and reconstruction of the (future) teachers’ collective perceptions, we see one possible way to gain an impression of the current perspectives of teachers and student teachers on dealing with the learners’ heterogeneity, especially in mathematics.

The documentary method offers [...] an access to the pre-reflexive or tacit knowledge, which is implied in the practice of action. Asking for the documentary meaning can [...] be understood as asking for *how*: how is practice produced or accomplished. (Bohnsack, 2010, p. 103)

So far, six group discussions have been held during which teacher students spoke about the general question: What kind of experiences have you made concerning the difference of learners in school and in class? The groups were homogeneous in terms of the participants’ school type. In each discussion, between four and seven student teachers spoke together for around one hour about their experiences in dealing with heterogeneity in the school context. Each discussion was video recorded and transcribed. This paper focusses on statements on the performance heterogeneity of students in relation to mathematics. We compare transcript scenes from two different group discussions (number two and four), because there the student teachers are from the same school type (high school) and all are teaching mathematics. As we described above, the teachers, in our case mathematic high school

teachers, tend to have the same or similar experiences and opinions. Because of their academic background they belong to a ‘conjunctive space of experience’. To answer the research question “What collective orientations about the learners’ heterogeneity in mathematics do student teachers have?” the scenes are analysed with a reflective interpretation. Within the framework of the documentary method, the stage of reflective interpretation is particularly promising for the identification and reconstruction of the ‘conjunctive space of experience’ (Mannheim, 1982).

## Results

From the very beginning of both group discussions, the focus was less on education in general than on mathematics, as the student teachers seem to have a ‘conjunctive space of experience’ concerning this topic. Differences in the learners’ achievement was a meaningful aspect of the discussion. Following the research question, we could identify the collective orientation that, especially in mathematics, performance differences are visible and challenging. We will illustrate this by showing short transcript extracts of group discussion number two and four, each followed by a brief analysis of the scene.

### Group number two

- Wiebke: I think in school you notice the performance gap and how different it is between the students. I think, especially in the subject math you always have these, [laughs] that are bomb in math and those, who do not understand it at all. To arrange the lessons in a way that all can somehow follow or are not under-challenged is quite difficult.
- Natalie: Yes. What is also always a topic are differentiated tasks, in a way, that either the tasks get more difficult in the end or the top-performing pupils get more tasks. And at the beginning the easier tasks. That is also addressed in teacher education. And also, that you should have extra tasks for those who are faster so they still have something to do or talk about. That happens all the time.
- Wiebke: But I think it is only about these differentiated tasks and for the faster pupil new tasks. I had a seminar, not in math but in English, where another heterogeneity, like language differences, was mentioned. And this could be transferred to math. Maybe a child is super good at math but just does not understand what's in the task. I think, you don't learn anything about this at university.

The first reaction on the impulse of the discussion concerned the differences in the learners’ performance. Wiebke argues, that in mathematics there are ‘always’ pupil who are extremely high achieving, what she illustrates with the metaphor of a bomb (which is a common expression in Germany) while there is also ‘always’ a group of pupils who do not understand mathematics at all. Through this dichotomous distinction, she describes from personal experience that it is ‘quite difficult’ to arrange lessons. The metaphorical use of ‘bomb’ for something exploding and powerful illustrates that such ‘bomb’ students are not necessarily considered by her as something positive. Natalie seems to understand Wiebke and argues that in university they ‘always’ heard something about how to use differentiated tasks and how to make sure they work. This could be seen as something positive. But in contrast to Natalie, Wiebke is not satisfied with this one-sided preparation

with the focus on achievement and tasks. In her opinion, it is also important to ‘learn’ something about other facets of heterogeneity, like language differences, which she emphasizes with the comparison to her studies in English. She notes that it is important for students to understand the tasks in order to solve them because linguistic competences are often needed to show mathematics performance. But her claim, to learn ‘nothing’ about this in university, could also be seen as an exaggeration.

### **Group number four**

Konrad: Especially during internships, I have seen great differences in the performance and skills. When you walk around during times of individual work, you could really see what the student is currently thinking about the task. As trainee that is usually very noticeable because you do not stand in front of the class but you help students in the back or walk around during individual work.

Niklas: Yes, I also noticed that. Either in middle school or in ‘pure’ high school classes. In one such pure high school it was such a monotony and all students were well-mannered and from suburban areas and tagged along even during the worst lessons. But even there you recognized achievement differences in mathematics like in middle school classes. Even in urban areas you have the same differences.

As in group discussion two, in discussion number four the reaction on the impulse for the discussion is about differences in achievement. Konrad's statement shows, that it seems easier to ‘see’ the learner's heterogeneity when you are not the person teaching in front of the class. Konrad seems to protect teachers as they are not able to ‘see’ differences when they have to concentrate on the lesson itself. Perhaps, he himself also made the experience of not being able to perceive so many achievement differences and to adequately respond to them when teaching himself. Niklas enlarges this topic by comparing different types of school and different environments. Either in (lower-achieving) middle school classes or in (higher-achieving) ‘pure’ high school classes, he claims that in mathematics the same differences in achievement exist. This also applies for urban and suburban areas. He points out one class of well-mannered students, which is a ‘pure’ high school class in a suburban area, which tolerates even the worst and most boring lessons.

### **Discussion**

Especially in the group discussion with high school student teachers for mathematics, differences in achievement was a central point of the discussion. In both conversations we could reconstruct the view, that especially in mathematics differences in achievement are suspected to be ‘visible’ and that teachers have to react to them through (differentiated) tasks. This aspect could therefore be seen as the most important for student teachers when they consider the heterogeneity of their prospective class in mathematics. It is noticeable, that it is less discussed, how differentiation of the content or the social formation in the class could look like. Differences in achievement seem to be important for the student teachers but possibly they don't know how to deal with this heterogeneity. The predication of Nathalie shows that theoretical knowledge of how to deal with heterogeneity and differentiated tasks has apparently been taught in the university. However, the two excerpts show that this knowledge cannot be applied in practice. This result also coincides with the four other group

discussions of the HeLeA project. Similarly to Gellert (2008) and Schieferdecker (2016), tensions were reconstructed which have to do with the problem of making pedagogical specialist knowledge (learned in university) compatible with the practice of teaching a heterogenic learning group. In all six group discussions, it was possible to reconstruct discontinuities between the everyday discourse of student teachers and the academic discourse on the subject of heterogeneity. One result of the HeLeA project is that the theoretical knowledge seems to be incompatible with the student teachers' experiences in school practice. To ensure that future teachers are more capable to apply the theory they have learned in practice, we have to give them tools to reflect their own lessons and train their ability to interpret situations. Personal practical experiences should be constantly analyzed and reflected in professional life – one possibility for this is team teaching. The results collected so far already provide initial insights into mathematics student teachers' collective orientations and guiding ideas on heterogeneity in mathematics (c.f. Bitterlich & Jung, 2019). One limitation of the used group discussions approach is that only collectively shared orientations can be reconstructed. What remains in the individual is hidden. But if we follow the assumption that teachers can be seen as a common group with shared experiences, collective orientations could be more important in certain circumstances.

# Teachers' noticing of language in mathematics classrooms

Carina Zindel

TU Dortmund University, Germany; carina.zindel@math.tu-dortmund.de

*Many studies point out teachers' crucial role in mathematics classrooms. This role is also emphasized through the increasing need of language-responsive teaching due to language diversity in the classrooms. The paper presents a qualitative study of teachers noticing mathematically relevant language issues in a video on a whole class discussion on variables. The study investigates which language resources and language obstacles the teachers notice and how they activate didactic categories of their content knowledge. It seems to be crucial to not only know the categories as disposition but also to activate them in a content-specific way.*

*Keywords: Pedagogical content knowledge, noticing, language-responsive teaching*

## Introduction

One important part of teachers' professional competence is their pedagogical content knowledge (PCK) (Shulman, 1986). Depaepe, Verschaffel, and Kelchtermans (2013) show that PCK has often been considered under perspectives of students' (mis)conceptions, instructional strategies, curriculum and others. Due to the increasing language diversity in mathematics classrooms, there is an increasing need of language-responsive teaching. However, only few studies deal with teachers' resources and obstacles when developing language-responsive mathematics classrooms (Radford & Barwell, 2016; Prediger, Sahin-Gür, & Zindel, 2018; Prediger, submitted). The aim of this study is to identify which language issues teachers notice in a classroom discussion and to analyze how they activate didactic categories when noticing these language issues. The article presents (1) the theoretical background of PCK and its role when noticing language issues, (2) the methods of the study, and (3) empirical insights which (mathematically relevant) language aspects teachers notice and how they activate didactic categories.

## Background of the study

### Identifying PCK in the connection from categories and practices

An important part of teacher knowledge is the pedagogical content knowledge (PCK) (for a literature review concerning different conceptualizations see Depaepe et al., 2013). In this context, Ball, Thames, and Phelps (2008) differentiate "knowledge of content and students" and "knowledge of content and teaching" (Ball, Thames, & Phelps, 2008, p. 399). They assume that "a clearer sense of ... content knowledge for teaching might inform the design of support materials for teachers as well as teacher education and professional development" (ibid., p. 405). This study aims at contributing to this clearer sense of content knowledge. Thereby, the study follows suggestions to focus not only the knowledge as dispositions but also on teacher practices (Depaepe et al., 2013) and the continuum from teachers' dispositions to performances in a situated perspective (Bloemeke, Gustafsson, & Shavelson, 2015). Our overarching project (Prediger, submitted; Prediger et al., 2018) is especially interested in the connections between teachers' (simulated) classroom practices and the knowledge

activated for these practices, following Bromme's (2001) conceptualization. More precisely, this study deals with the categories teachers activate for noticing in language-responsive teaching.

### Noticing as a relevant teacher practice in language-responsive teaching

In general, noticing is described as the process of making “sense of complex classroom environments in which they cannot be aware of or respond to everything that is occurring” (Jacobs, Lamb, & Philipp, 2010, p. 170). Noticing aspects consists of two processes: first “attending to particular events in an instructional setting” and second “making sense of events in an instructional setting” (Sherin et al., 2011, p. 5). Interpreting these events involves “relating observed events to abstract categories” (ibid., p. 5). Abstract didactic categories are the mental schemes that structure situations. This study defines these events or aspects as those utterances and actions that teachers could identify as language resources or language obstacles when activating abstract categories and relating them to learners' specific utterances or actions (Figure 1). Hence, the aspects teachers notice depend on their background pedagogical content knowledge (Prediger & Zindel, 2017).

**Figure 1: Noticing as activating PCK in a content-specific way**

In the case of language-responsive mathematics teaching, *noticing language* has been identified as one of five typical situational demands (Prediger, submitted). Here, *noticing language* is the foundation for further jobs such as *supporting language* or *developing language*. With respect to the relevant categories, noticing language requires attending to learners' obstacles, but even more on learners' language resources in order to take decisions for an adaptive support. Other studies also focus on noticing the resources. Kilic et al. (2019) for example investigate the effects of a faculty-school collaboration program with regard to preservice teachers' noticing of mathematical opportunities emerged from students' mathematics.

For the case of language-responsive teaching, it is important that teachers know how the language issues are tied to the teaching of their subject (Bunch, 2013, p. 299). Hence, language-responsive teaching requires knowledge on mathematically relevant language demands and adequate teaching practices. In order to consider both, teachers' knowledge and their practices, this study focuses on teachers' processes in PD-integrated diagnostic activities.

This study focuses on two (abstract) didactic categories, which several studies highlight when dealing with language responsive teaching: *word* level and *discourse* level (Moschkovich, 2015; Prediger, submitted). Studies have shown that students' obstacles and resources differ on these levels and that especially the discourse level is important for mathematics learning as language and mathematics are strongly connected on this level (Moschkovich, 2015).

## Focus of the investigation

Based on these theoretical backgrounds, the aim of this study is to identify which language issues teachers notice in a classroom discussion and to analyze how they activate didactic categories when noticing these language issues. Hence, the research questions are:

- (RQ1) *Which language resources and language obstacles do teachers notice when watching a video on a whole class discussion about the meaning of variables?*
- (RQ2) *How do teachers activate the categories word level and discourse level when noticing these language obstacles and language resources?*

## Methods

### Data gathering: PD-integrated diagnostic activity

In the overarching project, we conducted several PD-integrated diagnostic activities due to two reasons. First, these activities offer insights in teachers' knowledge and second, the facilitator can directly react and use the results in the PD. In this paper, the focus is on diagnostic activities of *noticing language*. We collected  $n=12$  written products on the diagnostic activity translated in Figure 2. The sample consisted of German middle and high school mathematics teachers in their third session of a volunteer professional development series on language-responsive mathematics classrooms. The transcript teachers should analyze after watching the video scene contains many different language resources and language obstacles (Figure 3, Figure 4). This richness allows analyzing which of these aspects teachers focus on and thereby teachers' noticing.

A grade 10 class worked on the following task and conducted a whole class discussion on the match:

**Classroom task:** Ms. Maier buys presents for her colleagues. One bottle of wine costs 3 Euro. Additionally, she needs one bag for 1 Euro. Does the function equation  $f(x) = 3x + 1$  fit to this situation?

**Activity for the teachers:** Watch the video of the whole class discussion and analyze the corresponding transcript [here printed in Figure 4] with regard to the learners' conceptual and language resources and obstacles.

**Figure 2: PD-integrated diagnostic activity on noticing language and identifying language issues**

In order to identify potential starting points for learning processes, teachers should identify mathematically relevant language obstacles and mathematically relevant language resources. A coding scheme of content-specific language resources (R) and language obstacles (O) that teachers could notice in this scene (Figure 3, Figure 4) was developed by, and discussed within, our research group. There is no hierarchy in the list. This list is not a complete list, so the coding scheme allows for additional individual categories (R9 and O7). Each noticeable aspect contains an (abstract) category (here: the discourse level/ different discourse practices) related to the observed event (i.e. utterance and/or action; Figure 1). After watching the video scene of the classroom discussion in the PD, the teachers should analyze the transcript with regard to conceptual and language obstacles and resources. We collected teachers' written products on this task and videotaped the whole PD including the group discussions in order to gain insights in the PD-processes.

- (R1) Differentiating the amount of colleagues and the amount of bottles  
 (R2) Explaining the meaning of  $x$  as number of bottles/colleagues  
 (R3) Explaining the meaning of the constant “3” as price of one bottle and the meaning of “1” as price of one bag  
 (R4) Generalizing the number of bottles/ colleagues  
 (R5) Describing a general relationship between the number of colleagues/bottles and the price by calculating values  
 (R6) Generalizing the number of bags  
 (R7) Describing a general relationship (between any amount of bottles/colleagues/bags/prices)  
 (R8) Explaining the meaning of variables as unknowns and generalizers  
 (R9) Further resource  
 (O1) No identifying the meaning of “1” as price of one bag  
 (O2) No generalization of the amount of colleagues/bottles  
 (O3) No explanation of the meaning of  $f(x)$  as total price  
 (O4) Inappropriate basis for argumentation when explaining the (non)match of the function equation  
 (O5) Overstressing the relevance of “colleagues” as singular or plural (A/N: both have the same spelling in German)  
 (O6) No explication of the functional relationship between the number of colleagues/bottles and the price  
 (O7) Further obstacle

**Figure 3: Coding scheme for noticeable aspects (utterances and actions) in the scene**

2	David	Hm, Ms. Maier buys [...] presents for her colleagues. One bottle of wine costs 3 Euro. Additionally, she needs one bag for 1 Euro.	
3	Max	[5s] For?	<b>O1</b>
5	Celina	Well, I don't think that fits, because hm I think (...) $f(x)$ equals 3 plus 1...	<b>O2, O4</b>
6	Fynn	I don't think that fits either, because it doesn't say how many bottles she buys (...)	<b>R1 O2</b>
7	Alexandra	I think that fits, because the function equation has $3x$ plus one. And three is then (...) the value of the bottles, $x$ are the colleagues. And plus 1 is what you only have to pay once, because the 3 are always with the colleagues (...)	<b>R2, R3, O3</b>
9	Altin	Hm. I think that fits, because hm $x$ is simply intended for the colleagues. So, if she had three colleagues, she would have to pay nine Euros.	<b>R4, R5</b>
10	Nils	[3s] It depends on hm whether she buys more than one bottle of wine. Because, if more bottles were bought, you could take the amount as $x$ and then the question fits.	<b>R2, R4</b>
11	Tatjana	Well I think it doesn't fit because the number of colleagues is unknown.	<b>O4</b>
12	Ben	I think, it also doesn't fit because the text says colleagues. And these are several and our function equation says $3x$ (...)	<b>O4, O5</b>
13	Christian	And if $3x$ , so the number of bottles is unknown, then you don't know how many bags you need either. Then this should be $x$ , too. You don't know how many bags she takes.	<b>R6, R7, O6</b>
17	Fynn	Well this does not fit because it is not given how many bottles the woman wants to buy.	<b>O4</b>
19	Max	It doesn't fit because the number [...] is not given, how many – for how many colleagues she needs how many bottles. Because it needs to be better [...] explained or presented.	<b>R1, R7</b>
21	Nils	It fits because the number of colleagues is $x$ . It is a non-determined number. That means, you can choose the number, how many colleagues there are.	<b>R8</b>
22	Alexandra	Well it says that the wine costs three Euro. And three is three times $x$ and $x$ is the unknown. That means that this is the number of colleagues. And it says she needs <u>one</u> bag. So she only buys one bag and therefor plus 1.	<b>R2, R3, O3</b>
24 - 26	Altin	The problem is, how big is the bag? Because [...] if there are more colleagues, then I don't think that all bottles fit into one bag and then she has to buy a second one. And then there would have to be plus two.	<b>R6, R7</b>

**Figure 4: Transcript of the discussion and noticeable language resources (R) and obstacles (O)**

## Data analysis procedures

This paper focuses on the results of teachers' written analysis of the classroom discussion. These written products of the teachers were analyzed by collecting the noticed language aspects and comparing them with the aspects R1-R9 and O1-O7 (Figure 3 shows the inductively generated coding scheme for noticeable aspects). As teachers do not make the distinction of resource and obstacle explicit in their products, also utterances or aspects that *could* be used as a resource are coded as noticed resource (This reflects a resource-oriented positioning towards teachers' products.) Following the conceptualization of "noticed aspects" as "abstract categories related to specific utterances or actions" (Figure 1), teachers' written products were also analyzed with regard to the question *how* they activate the (abstract) categories *word level* and *discourse level* and especially whether they activate them in a content-specific way.

## Results

### Insights into three cases

In a first approach, the paper presents three cases of teachers' written products (Figure 5) in order to illustrate the functioning of the coding scheme (language-related aspects are highlighted in black).

<b>Camilla Lippott</b> - Meaning of $f(x)$ and $x$ is not clear for many learners, as well as the meaning of the 1 - changing meaning of $x \Rightarrow$ number of colleagues; number of bags - David: only reads aloud, does not participate in the discussion (O7) - Max: does not recognize the meaning of the variable - Alexandra seems to have understood the assignment, but has difficulties in verbalizing (O7) - Celina does not give reasons at all (O4)	
<b>Selma Ludwig</b> <u>Mathematical resources &amp; difficulties</u> • Meaning of the variable $x$ not clear (Fynn, Max, Celina) • Notion of variable not clear • Additional variable for bags (Altin, Christian)	<u>Language resources &amp; difficulties</u> • Colleagues $\neq 3x$ ? (O7) • Meaning of "Does the function equation fit?" not clear (O7) • <u>One bag</u> (O1) • Explanation linguistically vague (Alexandra) (O7) • Number of colleagues $\neq$ Colleagues (O5)
<b>Peter Tremnitz</b> - Max for? unknown (by, for) (O1) - Celina creates a model on her own (and in a wrong way) instead of analyzing the given term - Fynn struggles with interpreting the $x$ as variable - Alexandra has understood the problem, but she can only insufficiently verbalize the meaning of the 1 (for one bag) $\Rightarrow$ clarifies it later (O6) - Tatjana does not find a concrete number of colleagues – obstacle in functional relationship - Ben: $3x$ – not interpreted variable - Christian: it remains unclear whether he imposes an upper limit for one bag or whether he regards the number of bags as proportionally increasing. The task says that she needs only one bag. (R6, R7) - Altin: $+1$ incorrectly interpreted repeatedly	

**Figure 5: Three cases of teachers' written products and their coding**

Camilla points out that David only reads aloud and does not participate in the discussion (O7). Hence, she activates the category discourse level in terms of participating in the classroom discourse. Besides, she states that Alexandra struggles with verbalizing the functional relationship (O7). Thereby, she names the discourse practice of verbalizing, but she does not explicitly relates it to the observed

utterance. It remains unclear which difficulties Alexandra might have and whether these are difficulties in finding correct words on a lexical level or whether she has difficulties in explaining on the discourse level for example. A similar category could underlie her observation that Celina does not give any reasons at all (resp. inappropriate basis for argumentation, O4).

In contrast to the two other teachers, Selma makes an explicit distinction between mathematical aspects and language aspects. She identifies five language obstacles: O1, O5 and three further obstacles that are summarized under O7. The further obstacles are (1) identifying the meaning of “3x” as number of colleagues, (2) no understanding of the question, and (3) explanation linguistically vague. Thereby, Selma activates the category “discourse level”, too. However, she describes the aspects only partly by only naming the abstract category (“explanation vague”) or by only naming a part of the situation (“one bag”). It remains unclear which categories she relates to which observed utterances.

Peter recognizes the possible idea of generalizing the number of bags R6 as “proportionally increasing” (R7). Thereby, he notices an utterance that could be used as a resource for the discursive demand of generalizing and describing a general relationship, even though this is not the relationship focused by the task. Peter activated the category “discourse level”, too, by explicitly relating the discourse practices to the observed utterances in most cases.

Whereas Camilla and Selma only notice obstacles, Peter also identifies a potential resource, although he does not make explicit that it is a resource. Nevertheless, noticing such aspects is presumably a first step towards responding to those utterances in an appreciative way.

### Teachers’ noticing of language resources and language obstacles

Figure 6 presents a summary of the coding of all twelve teachers’ products with regard to the amount of noticed resources and noticed obstacles, sorted by teachers (Figure 6, left) and sorted by aspects (Figure 6, right).

**Figure 6: Amount of noticed resources and noticed obstacles by teacher (left) and by aspect (right)**

It is striking that teachers notice much more obstacles than resources (Figure 6). Only four teachers notice resources at all, but even these four teachers notice only one or two utterances that could be used as resources in the whole scene (Figure 6, left). These observations raise the question, why teachers notice some aspects very often, whereas other aspects are not noticed at all. In order to identify possible reasons for these observations, the following section investigates teachers’ underlying categories in their noticing.

### Teachers' activated categories in their noticing of language obstacles and resources

As teachers focus much on the aspects O1 and O5 (Figure 3), they seem to focus on demands on a *word level*. This problem is already well known (Moschkovich, 2015; Prediger et al., 2018). Both aspects describe obstacles that result from wrongly understood words in the text. For noticing other aspects it would have been necessary to activate further categories like other discourse practices on the discourse level and relating them to learners' utterances.

In the three presented cases, all teachers activate the category *discourse level*, although they do this on different ways. Some teachers remain on the discourse level in a general way (like Camilla), others differentiate several discourse practices (but name only the category or only the utterance like Selma) and others differentiate discourse practices and relate them explicitly to the observed utterances or actions (like Peter). The same phenomena become visible in other cases, too. These observations are paralleled by the fact that some teachers differentiate single students whereas other teachers describe to resources and obstacles of the class as a whole.

Summing up, teachers focus much more on language obstacles than on language resources. If they identify language resources, they remain on the word level. Only few teachers notice different discourse practices that could be built on although there are many different noticeable discourse practices in the scene that could be used as a resource in a further classroom discussion (Figure 3, Figure 4). If activated at all, the categories on the discourse level are often activated in a general way, i.e. that the abstract categories are not explicitly related to the observed utterances or actions.

### Discussion and outlook

Noticing aspects consists of two processes, "attending to particular events" and "making sense of events" (Sherin et al., 2011, p. 5). For the case of language-responsive teaching, this paper has investigated which aspects teacher notice and how they activate the in this case important didactic categories *word level* and *discourse level* (concerning the two categories cf. Moschkovich, 2015; Prediger, submitted). The results show that teachers focus much more on language obstacles than on language resources. Such a deficit-oriented focus presumably leads to unused learning opportunities, as the existing resources are not identified as possible starting points for learning processes.

Teachers' noticing depends on teachers' background knowledge of didactic categories (Prediger & Zindel, 2017). However, it seems to be not enough to know the categories as teachers remain very vague in their articulation of the noticing. So knowing a category seems to be only a first step in a category-based noticing. A further step is activating a category in a content-specific way, i.e. not only naming the abstract category, but also relating it to the observed mathematical issue (cf. Figure 1). It might be helpful if PDs dealt with possible language resources and language obstacles that could be expected in different math contents. Hence, PDs should support teachers in acquiring didactic categories as well as activating them in a content-specific way in order to support teachers' noticing.

Of course, the results gained by a sample of  $n=12$  must be interpreted cautiously. We continue the data gathering in following PDs, so that this sample will be enlarged. Furthermore, we are going to analyze how this first noticing develops in group-discussions in the PDs. We will analyze the video material of the PD in order to gain deeper insights in teachers' noticing and its development.

**Acknowledgement.** The presented study has been conducted within the project MuM-innovation which is financially supported by the German Ministry of Education and Research (BMBF-research grant no. 03VP02270 to S. Prediger) in the framework of DZLM, the German Center for Mathematics teacher education (which is financially supported by the German Telekom-Foundation).

### Introduction

TWG21 met for the second time in Utrecht at CERME11 and in this conference we sought to continue the work started at CERME10. The aim of the previous meeting was to ascertain where the interest of our community is when thinking about assessment, and to maintain the focus firmly on mathematics. At CERME11 we discussed 14 papers and 3 posters which helped defining such interest. We noticed again a variety of focal points: from validation of large-scale assessment instruments, to the affordances and drawbacks of online assessment – especially in the university context - to the details of construction of individualised feedback. As in the previous meeting the papers also presented a variety of methodologies: from large quantitative studies to more nuanced qualitative investigations. Among the submissions we also received papers related to students' perspectives and teachers' perspectives on assessment. These themes were not prominent in the past meeting of the group and we welcomed the new perspectives they brought. Finally, we decided to group papers together that indicated the role that mathematics has in the assessment: this is to say papers that focus on the specifics of mathematics, such as assessing proof.

### Thematic clusters

We identified 5 overarching themes that will serve to organise the papers submitted to TWG21. Below, we describe each of these themes in turn.

**Large scale standardised assessment:** There is strong interest in our community for the use and validation of large-scale standardized assessment, both for benchmarking national students' attainment and for mapping common misconceptions across educational stages. Garuti and Martignone present the introduction of the INVALSI standardised tests in Italy and then investigate the possibility to assess argumentation through the multiple-choice questions included in the INVALSI tests. By using Toulmin's model (1958) to analyse the structure of arguments included in the tests the authors find that although standardised multiple-choice arguments can identify only certain aspects of argumentation, this is not to say that the aspects that these tests do identify have no educational value. They conclude by proposing that the Toulmin's model (1958) could be used to guide the construction of such tests. Klegseth, Kaspersen and Solstad use Rash Analysis to determine

whether non-standardised test included in Norwegian textbooks are a valid and reliable indicator of mathematical competence. In order to do so the authors focused on the concept of function. The items tested were divided into 5 competencies categories and the authors found that, with a careful selection of such test items, the set they identified can be a reliable and valid measure of mathematical competences for these students. Drüke-Noe and Siller present a newly developed test with easy tasks which assesses basic mathematical competencies that are essential for vocational training. The test is used in years 8 and 9 in Germany. From both a content-oriented and a process-oriented perspective, preliminary test results reveal a substantial lack of these competencies in all academic tracks, and differential effects were found with respect to year and class that need to be examined beyond curricular analyses. Finally, Lasorsa, Garuti, Desimoni, Papa, Costanzo and Ceravolo also worked from the database generated by the INVALSI test for mathematical proficiency in Italy and investigated the psychometric and qualitative-educational properties of a pool of these questions. They seek to find specific cognitive obstacles that the students need to overcome to reach the desired competence levels.

**Assessment with technology and Computer Aided Assessment (CAA):** As in CERME10 we received papers on the use of technology for assessment, both papers at university level. Sangwin reports the development and evaluation of an online linear algebra examination administered using the system STACK (Sangwin, 2013). The aim of this study is to investigate whether common questions in linear algebra could be assessed automatically, which was the case for most of the questions tested. The implication for the assessment of mathematics are that tools need to be created and tested to assess explanation, justification and reasoning, and that the current questions of paper-pencil test should be reconsidered since they often focus on mechanical processes. Barana and Marchisio report the implementation of automatic assessment methods both in classroom activities and in online homework tasks to enact formative assessment strategies. The aim of such implementation was to foster self-regulation in the students. Their findings illustrate how formative assessment strategies can be implemented into such a blended-learning setting and how students perceived the effectiveness of the experiment.

**Assessment of mathematics: the teachers' perspective:** We received four contributions on this topic, all reporting research in school settings. Horoks, Pilet, Coppé, De Simone and Grugeon-Allys present the design of a large-scale questionnaire aimed at analysing teachers' assessment practices and how teachers use the information they gather to promote students' learning, in the context of algebra. The authors discuss the design of suitable questions to gather information on the diversity of teachers' assessing practices. Kaplan, Kan and Haser present a study that investigated preservice middle school mathematics teachers' (PST) professional development related to formative assessment practices and focus on how preservice teachers' practices changed during the teacher education program. The authors explored PSTs' performance on a task where they were asked to analyse a lesson plan without any formative assessment opportunities built in and found PSTs did not always realise the lesson plan lacked any formative assessment, especially if they had not yet attended to measurement and assessment courses and methods of teaching courses. Moreover, PSTs were keener to suggest assessing strategies based on their role as teachers, and less to insert peer assessment into the plan. Sangari, van den Heuvel-Panhuizen, Veldhuis and Gooya report preliminary results of

a survey of Iranian teachers aimed at investigating to what extent teachers engaged with Descriptive Assessment, an approach for evaluating students' achievement by collecting and documenting evidence regarding their learning and performance. The survey showed that teachers engage with some of the formative assessment tasks, although not as frequently as it would be desirable. Finally, Prendergast, Treacy and O'Meara presented a study concerning teachers' perceptions of the Bonus Point Initiative (BPI) in Ireland. This initiative consists in awarding an extra 25 points in final examination results to those students who choose to study mathematics at higher level. The study adopted a mixed-method design. Findings show that, although teachers recognized the value of the BPI initiative in promoting the study of mathematics and recognizing the effort paid by students in studying maths at higher level, many of them feared that the BPI may decrease the standard of students attending to higher level courses.

**Assessment of mathematics: the students' perspective:** These papers focused on the impact of assessment on students' experiences and attitudes both at school and university levels. Demosthenous, Christou and Deetra Pitta-Pantazi propose a framework for designing different types of assessment tasks to elicit evidence about how students respond to the mathematical ideas presented in learning trajectories. The authors illustrate the application of the framework by drawing on a learning trajectory of fraction division for sixth grade students and discuss how the enactment of the trajectory in classroom could be adjusted to students' current understanding. Häsä, Rämö and Viii Virtanen discuss a study part of an ongoing larger project concerning student self-assessment skills in university courses. The authors developed a method enabling large cohorts of students to assess their own learning outcomes and to give their own course grades with the help of an automatic verification system. The paper explores whether the self-assessed grades correspond to the students' actual skills, and how well the automatic system can detect issues in the self-assessment. Based on an expert's evaluation of the skills of two students, the study concludes that although for large part the model works as intended, there are some cases where neither the self-assessment nor the computer verification seem to be accurate. Bóra and Juhász discuss pair-work testing. Their pilot study consisted of four tests: twice students were tested in pairs and twice students were tested individually. The researchers recorded the marks and overall performance of the two-two sets of each type of tests. Online questionnaires revealed that in general students had a positive attitude towards paired testing: they rated positively the concept and they rated their testing experience positively. In addition, the overall level of paired work was high. The authors point to the need to continue the study with a larger number of students to learn more about how paired testing improve collaboration and mastery of skills.

**Aspects specific to the assessment of mathematics:** Starting from the work in our previous meeting we wanted to emphasise the role of mathematics in the assessment, e.g. the specifics of assessing mathematics. We received four contribution to this topic. Bolondi, Ferretti and Santi use the framework of didactical situations (Duval, 1995) to investigate the persistence of certain mathematical misconception across educational stages (e.g. from school to university mathematics). By analysing the data collected in the database generated by the INVALSI test for mathematical proficiency in Italy the authors found that certain misconceptions concerning the operations between exponentials persist across the school to university transition, for low as well as medium attaining

students. Watkins, Lamm, Kohli and Kimani investigate the relation between characteristics, beliefs, background and perception of students on student attainment in the context of US Community Colleges, a much under-researched area. Using linear regression on a large database collected for the study they are able to individuate some predictors of student achievement and conclude that rich professional development opportunities for teachers have the potential to enhance teachers' effectiveness in this context. Cusi and Telsoni describe the design of individualized teaching/learning paths in the context of formative assessment at university level. The paths are designed to be tailored to the students' responses to online test and provide tailored feedback at each stage of the test. Preliminary results show how students interact with the feedback received and highlight that few students are aware both of the difficulties they have in solving the problems and how to overcome them. The individualized teaching/learning paths have the potential to develop the awareness of strategies to overcome difficulties. Finally, Turiano, Boero and Morselli explore the emergence of a 'culture of theorems' (Boero, 2007) through assessment involving narratives in a 10<sup>th</sup> grade classroom. After the students were taught some Euclidian geometry they were given as part of their assessment the task to write to a friend in another school and explain what a theorem is. Preliminary analysis of the narratives shows instances of students' meta-mathematical knowledge regarding the culture of theorems.

## Conclusions

The papers that were presented in the TWG21 indicated once more the variety of interests in the assessment of mathematics community, both in terms of focus and of methodologies. Again we received papers adopting quantitative methods (such as Rasch analysis) and papers focusing on small in depth case studies. This reflects the variety of approaches in our field and it is normal that this variety emerges on the work of our group. However, while in the past meeting we found that authors were concerned by the lack of a shared language to discuss assessment, this time we welcomed more agreement on basic definitions. The emphasis that we detected on students' and teachers' perspectives also indicate the need for investigating how assessment affects those participating in it, following the observation we made at CERME10 of a lack of studies on this topic. Again, we sought to maintain the focus on mathematics – e.g. we highlighted the impact of the discipline characteristics on the way in which we think about assessment, both summative and formative. Finally, we plan to meet again at CERME12 in Bolzano (Italy) to push forward the work of the group and our thinking on the assessment of mathematics.

# Strategies of formative assessment enacted through automatic assessment in blended modality

Alice Barana<sup>1</sup> and Marina Marchisio<sup>2</sup>

<sup>1</sup>Department of Mathematics of the University of Turin; Turin; Italy; [alice.barana@unito.it](mailto:alice.barana@unito.it)

<sup>2</sup>Department of Mathematics of the University of Turin; Turin; Italy; [marina.marchisio@unito.it](mailto:marina.marchisio@unito.it)

*This paper intends to contribute to the research on formative assessment in Mathematics providing a model of automatic assessment aimed at enhancing learning and self-regulation. The model was developed at the Department of Mathematics of the University of Turin (Italy). The main features of the model are: availability, algorithmic questions, open answers, immediate feedback, interactive feedback, and real-life contextualization. The effectiveness of the model to enact formative strategies is discussed through the results of a didactic experimentation involving 299 students of 8<sup>th</sup> grade, where automatically assessed assignments have been used both during Mathematics classes and as online homework.*

*Keywords: Automatic assessment, computer assisted instruction, feedback, formative assessment.*

## Introduction

It is widely acknowledged that assessment has a great influence on learning, impacting on when and how students work and learn. In particular, formative assessment practices help develop understanding and motivation, encouraging positive attitudes toward learning. Being responsive to the users' actions, digital technologies can make new room for formative assessment: with their capabilities of computing grades and offering feedback in real time, they can return information to students and teachers that is relevant to support and enhance learning processes. Web-based digital materials with automatic assessment can be used in face-to-face, blended or online courses; according to the modality adopted, they can facilitate personalized approaches as well as foster peer discussion.

This paper intends to contribute to the research on computer aided assessment in Mathematics, by proposing a model of automatic formative assessment and interactive feedback developed by the Department of Mathematics of the University of Turin (Italy). After a brief review of the literature on formative assessment, feedback and automatic assessment, the paper shows a model of automatic formative assessment using a system based on an Advanced Computing Environment, particularly effective for Mathematics. The model is discussed through some results of a didactic experimentation which involves 8<sup>th</sup> grade students.

## Theoretical framework

### Formative assessment

The term “formative evaluation” was coined by Michael Scriven in 1966 in opposition to “summative evaluation”, to describe a practice aimed to collect information during a course in order to develop the curriculum (Scriven, 1966). Benjamin Bloom borrowed the term to indicate a strategy for mastery learning, namely a set of diagnostic-progress tests which should assess the achievement of the small units in which the program is divided (Bloom, 1968). Bloom's studies evidenced the effectiveness of

this strategy to motivate students to forge ahead with the learning path. In 1989 D. Royce Sadler highlighted the role of feedback as a key distinction between formative and summative assessment. Sadler conceptualized formative assessment as the way learners use information from judgments about their work to improve their competence (Sadler, 1989).

More recently, Paul Black and Dylan Wiliam contributed to the development of a theoretical framework for the formative assessment, with particular reference to Mathematics Education. They spoke about formative practice, giving the well-known definition:

practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited. (Black & Wiliam, 2009)

They individuated five key strategies through which formative practices can be enacted, involving students, peers and teachers: clarifying and sharing learning intentions and criteria for success; engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; providing feedback that moves learners forward; activating students as instructional resources; and activating students as the owners of their own learning.

## **Feedback**

The provision of feedback is the most distinctive feature of formative assessment. The power of feedback emerges in Hattie's metanalysis where it is considered one of the most effective strategies for learning (Hattie, 2009). John Hattie and Helen Timperley expanded upon the model of good feedback, conceptualizing it as "information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding" (Hattie & Timperley, 2007). Effective feedback, whose purpose is to reduce the discrepancy between current and desired understanding, indicates what the learning goals are, what progress is being made toward the goal and what activities need to be undertaken in order to make better progress. Feedback can work at four levels: the task level, giving information about how well the task has been accomplished; the process level, showing the main process needed to perform the task; the self-regulation level, activating metacognitive process; the self-level, adding personal evaluations about the learner.

Sadler emphasizes the focus on the learner's processing of feedback, noticing that if the information is not elaborated by the learner to alter the gap between current and reference performance, it will not have any effect on learning (Sadler, 1989). In order for feedback to be effective, students have to possess a concept of the standard being aimed for, compare the actual level of performance with the standard and engage in appropriate action, which leads to some closure of the gap.

Besides improving understanding, feedback can also be effective to enhance self-regulation, a process whereby learners set goals for their learning and monitor and regulate their cognition, motivation and behavior through internal feedback (Pintrich & Zusho, 2007). The process of generation of internal feedback can be facilitated by well-designed feedback which, according to Nicol and Macfarlane-Dick (2006), should clarify what good performance is; facilitate the development of self-assessment; deliver high quality information to students about their learning; encourage teacher and peer dialogue

around learning; encourage positive attitudes, motivation and self-esteem; provide opportunities to close the gap between current and desired performance; and provide information to teachers that can be used to help shape the teaching.

### **Automatic assessment**

Automatic assessment is one particular form of Computer Aided Assessment, characterized by the automated elaboration of students' answers and provision of feedback. Multiple choice is the most common question format; it is supported by the majority of online platforms, even though it considerably limits the cognitive processes involved in answering, especially in Mathematics (Bennett, 2012). To overcome this limitation, research centers and universities started to develop systems that are able to process open-ended answers from a mathematical point of view and to establish if they are equivalent to the correct solutions. Examples of similar Automatic Assessment Systems (AAS) are STACK, relying on the Computer Algebra System (CAS) Maxima (Sangwin, 2015) and Maple T.A., running on the engine of the Advanced Computing Environment (ACE) Maple (Barana, Marchisio, & Rabellino, 2015). By exploiting programming languages or mathematical packages, these AASs allow to build interactive worksheets based on algorithms where answers, feedback and values are calculated over random parameters and can be shown in different representational registers. Thus, new solutions for computer-based items can be conceived, including dynamic explorations, animations, symbolic manipulation that offer students experiences of mathematical construction and conceptual understanding (Stacey & Wiliam, 2013).

### **A model of formative automatic assessment for Mathematics**

The Department of Mathematics of the University of Turin has designed a model for creating questions conceived for the formative assessment of Mathematics, using Moebius Assessment. (formerly known as Maple T.A.). This AAS was chosen for its powerful grading capabilities, for the robust mathematical engine running behind the system and for the possibility of integration within the Virtual Learning Environment (VLE) Moodle (Barana & Marchisio, 2016).

Aiming at enhancing learning and self-regulation, automatically assessed assignments should have the following features (Barana, Conte, Fioravera, Marchisio, & Rabellino, 2018):

- availability: students can attempt the assignments, integrated in a VLE, at their own pace, without limitation in data, time and number of attempts;
- algorithm-based questions and answers: random values, parameters or formulas make questions, and their answers, randomly change at every attempt. Though variables based on algorithms, random parameters, mathematical formulas, graphics and even animated plots can be shown in questions and feedback;
- open-ended answers: the multiple-choice modality is avoided whenever possible; open answers, given in different representational registers (words, numbers, symbols, tables, graphics) are graded through algorithms which verify if the student's answer matches the correct one, independently of the form;
- immediate feedback: results are computed in a very brief time and they are shown to the students while they are still focused on the task. Brief assignments are advised, in order to increase the immediacy of feedback;

- interactive feedback: just after giving an incorrect answer, the system can go through a step-by-step guided resolution that interactively shows a possible process for solving the task, which recalls previous knowledge and engage students in simpler tasks. They can gradually acquire the background and the process that enables them to answer the initial problem. They earn partial credits for the correctness of their answer in the step-by-step process;
- real-life contextualization: whenever possible, questions refer to real-world issues, which contributes to the creation of meanings and to a deeper understanding, as students can associate abstract concepts to real-life or concrete objects.

The feedback provided through this model acts not only at the task level, giving information about the correctness, but also at the process level, showing the steps toward the solution. Moreover, it can also act at the metacognitive level, providing opportunities for self-assessment, engaging less motivated students in active drills and offering partial credits for correct answers. This feedback satisfies the conditions individuated by Nicol and Macfarlane-Dick (2006) for the development of self-regulation. This model is particularly relevant in making students elaborate the feedback, as it is displayed interactively while they are still engaged with the task. Feedback can be effective according to Sadler's model: in fact, the interactive feedback offers a concept of standard that students can actively possess; immediate feedback helps them compare the actual level of performance with the standard; when trying the assignment again, students find similar tasks with different values, so that they are engaged in an activity that makes them repeat the process until mastered.

## Research questions

The focus of this paper is to show how automatic assessment, implemented in a blended modality through classroom activities and online work, allows the enactment of formative strategies in order to enhance learning and self-regulation. In particular, the paper investigates whether the interactive feedback can be effective according to Sadler's model and whether the blended use of the automatic assessment can support formative assessment's strategies.

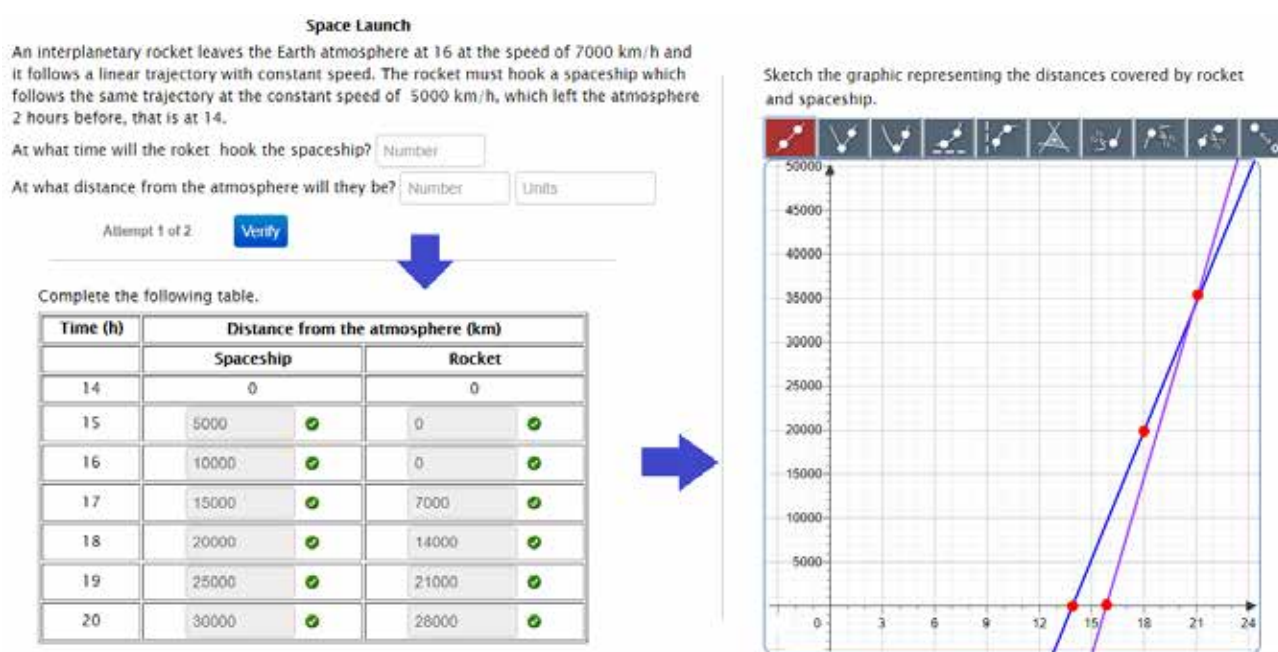

## Didactic experimentation and data collection

A set of materials designed according to the model illustrated above has been proposed to 13 8<sup>th</sup> grade classes of 6 different lower secondary schools in the town of Turin, for a total of 299 students, during the school year 2017/2018. Interactive materials with automatic assessment, organized in 10 different units, were created by university experts and inserted in a dedicated VLE. The tasks were mainly designed using items from the INVALSI surveys, the national standardized tests that take place annually in Italy, in collaboration with an INVALSI expert, expanded and adapted to the automatic assessment. Mathematics teachers, working in close connection with the researchers, could use the materials in two modalities:

- in the classroom, with the support of the Interactive Whiteboard (IWB), where tasks were displayed. Students, in small groups of 3 or 4, were asked to solve one task. All the answers were collected by the teacher, one was collectively selected to be checked using the AAS. After verifying whether it was correct, all the groups, in turn, had to show their solving process to the others. The interactive worksheets displayed at the IWB supported the collective discussion and gave prompts for deeper reflection.

- for homework, using the online assessment and the interactive feedback to check understanding. Students could autonomously navigate within the platform and make one or more attempts to the assignments.

One example of question is shown in Figure 1. It asks students to solve a problem about linear models, open to different approaches. Students who give the incorrect answer to the main task are engaged with the exploration of the situation through a table to complete and a graphic to draw interactively. This question has been used online with some classes and in the classroom with others. On the platform, students were guided through the solving process and could repeat the problem with different data; in classroom, only the main task was displayed initially and the different solutions made by the groups of students were shared and discussed, with the support of the automatic assessment. During the experimentation, a PhD student participated to the lessons regarding the module on functions and modeling, the target topic of the experimentation. Lessons were videotaped and all data from platform usage were extracted in order to study the use of the assignments. The appreciation of the activities was measured through a questionnaire distributed at the end of the school year.

**Figure 1: Example of automatically assessed question**

## Results and discussion

In order to evaluate whether the interactive feedback was effective according to Sadler's model, the usage and results of online assignments were analyzed. For each student the average number of attempts per assignment has been computed: it ranges from 1 to 12, with an average value of 1.70, which expresses students' tendency to repeat the questions. Then, the average grade each student earned in their first assignment attempt was compared with the average grade they earned in their last attempt through a pairwise Student t-test: the mean of initial grades resulted to be 51.55/100 (standard deviation: 19.63), while the mean of final grades was 59.02/100 (standard deviation: 19.87); the

increase is statistically significant ( $p < 0.0005$ ). These results show that students used the information provided in the feedback to improve their results in subsequent activities.

Answers to the final questionnaire show students' perceived effectiveness of the automatic assessment. Table 2 reports the percentage of students' answers, given in a Likert scale from 1 (completely disagree) to 5 (completely agree). In particular, it emerges that students appreciated the usefulness of the group work in the classroom, supported by the use of the platform, and the online tests with immediate feedback. The low percentages of negative answers show that the feedback obtained through automatic assessment and peer work was useful to develop conceptual knowledge, since students could better understand the topics; it was also effective at a process level, to understand how to solve the problems; and at a metacognitive level, developing awareness of one's preparation.

Questions	1	2	3	4	5
Working in group was useful.	1.4%	6.3%	23.1%	38.5%	30.8%
Class activities were useful to better understand some Mathematical topics.	1.4%	4.5%	29.1%	45.9%	19.1%
Using the platform during classroom lessons was useful.	0.5%	3.6%	32.1%	47.1%	16.7%
I appreciated the possibility to revise the material used in class through the platform.	0.0%	8.2%	35.3%	36.4%	20.0%
The online exercises were useful to better understand the topics.	2.5%	5.6%	20.5%	46.0%	25.5%
The online exercises helped me make clear if I understood the topics.	2.5%	14.3%	26.7%	37.3%	19.3%
It is useful to have the correct answer displayed immediately after answering.	1.2%	3.7%	13.0%	36.0%	46.0%
The immediate assessment helped me understand how to answer the questions.	1.2%	5.0%	19.9%	32.3%	41.6%
Problems with step-by-step guided resolution helped me understand how to solve the exercises.	1.2%	8.7%	26.7%	34.2%	29.7%
Online exercises helped me to be aware of my preparation.	3.7%	8.1%	28.6%	40.4%	19.3%

**Table 2: Student's answers to the final questionnaire, given in Likert scale 1 to 5**

The open answers to the questions "what did you appreciate the most?" and "what were the online assessments useful for?", evidenced how the use of automatic assessment both in classroom and online supported the enactment of the strategies of formative assessment. Comments such as: "in my opinion, online exercises are useful to better understand the process to build a formula", "the platform was very useful to better understand both the current topic and the resolution of problems" and "I think that the online tests were useful, because they showed me the many possibilities to solve one

problem” show how online assignments could clarify and share criteria for success. Tasks in the online tests were effective to elicit evidence of students’ understanding, as other students report: “online tests were useful because only by doing them I was able to acknowledge whether I had understood a topic or not”, “online tests were useful to individuate the points where I should improve”. Other comments prove that automatic and interactive feedback supported learning improvements: “I could have immediate access to the result to understand where I made a mistake and I had the chance to make another attempt with different data to drill”, “with the book you can do the assignments but you can’t acknowledge if your resolution is correct, while the platform always shows you both the correct answers and the solving processes”, “if you don’t understand a topic, with guided exercises you can gradually learn how to solve them autonomously”, “in classroom it often happens that I think I have understood a topic, but the next day I can’t understand it anymore, while with the platform I can work whenever I need to”. The assignments were also effective to activate students as owners of their own learning, as they themselves report: “technology encourages youngsters to work hard with homework, therefore they can better understand Mathematics”, “during classwork or homework I often felt willing and happy to solve the exercises, and they were useful to understand the lesson”, “I appreciated the online tests because they made me reason and work hard; sometimes I also had fun when doing Mathematics”. Groupwork was very appreciated and it allowed students to be activated as learning resources one for another, as their comments show: “classroom lessons were useful because, besides solving problems, we had to interact with each other and this allowed us to better understand the tasks”, “I appreciated reasoning together on the things that we were not able to do”, “I appreciated sharing ideas with classmates and helping each other”.

## Conclusions

The results of the experimentation reported above show that the blended use of the online assessment made it possible to activate all the agents of the formative assessment (students, peers and teacher) and all the 5 key strategies individuated by Black and Wiliam: in the classroom, students received feedback from discussion and sharing ideas with peers, while on the platform the interactive feedback offered a guided support for understanding concepts and processes. This conception of automatic assessment provides enhancements with respect to paper-and-pen work and traditional book exercises: students can individuate their mistakes and make more attempts to improve their understanding, they can be actively engaged in Mathematical work and even have fun, although items are not game based. The results of this experimentation gave prompts for the activation of other research projects, aimed at studying the impact of these methodologies on students of different levels and backgrounds, as well as for the application of this model of formative automatic assessment to the learning of other subjects, even outside the STEM area, thus starting interdisciplinary collaborations.

## Acknowledgments

We would like to thank Stefano Boffo, Francesco Gagliardi (CNR) and Rodolfo Zich (Fondazione Torino Wireless) for promoting the project and for participating to its realization. We are also grateful to Rossella Garuti (INVALSI) who collaborated to the development of the didactic materials.

*In this work we show the use of the INVALSI database as an instrument to collect organized data from national standardized tests in order to study students' mathematical thinking on a large scale. It allows us to create appropriate correlations to single out the behavior of the students relative to a specific mathematical topic or a cognitive issue. In this study we have used the INVALSI database to study how grade 10 students work with powers in the domain of algebra. We analyze the quantitative data within a semiotic theoretical framework. Analyzing items taken from the INVALSI tests we are able to single out a general behavior that involves a population of Italian students and that persists in time. We interpret the results within our theoretical framework, thereby giving a quantitative validation to a theoretical perspective that has been proven consistent by qualitative investigations.*

*Keywords: Standardized assessments, qualitative and quantitative methodologies, algebra, semiotics, powers.*

## Introduction.

It is more than 10 years that the Italian Ministry of Education (MIUR) has established national standardized tests (INVALSI) in mathematics. In detail, every year since 2008 INVALSI administers Italian and Mathematics (and since 2018, English) large-scale assessment tests to Italian students from Primary School to High Secondary School. The tests are devised according to a robust theoretical framework that has been developed according to mathematics education research. As we will see, a key tool that made it possible to focus our investigation was a database containing data about the INVALSI assessment.

The aim of this paper is to show how the INVALSI database can be effectively used also for research purposes. We study how high school students deal with powers analyzing their answers to items that have been administered throughout several school years. The items have been collected using the INVALSI database GESTINV (Gestinv, 2018) in order to single out consistent data regarding powers.

Our research interest focused on syntactic aspects because INVALSI tests show that Italian high school students have severe difficulties in handling the meaning of algebraic formalism when dealing with powers. This is particularly interesting if we take into account the efforts and attention that both students and teachers devote to algebraic calculations in the first two years of high school.

Our study wants to shed some light on the following issues:

What information can standardized assessments provide about student's learning difficulties regarding powers? What research tools can we use?

What information can we acquire from standardized assessments about mathematical practices in Italian high schools?

## Theoretical framework.

Gestinv is a database which includes all the administered INVALSI tests in Italy. There are now 13,000 users amongst in service and preservice teachers and researchers. As regards mathematics there are almost 1700 items available.

Gestinv contains all the items of the INVALSI tests indexed according to the National Curricula, the results from the statistical point of view, the content, the key words, the percentage of correct, wrong and invalid answers and other characteristics. It is possible to carry out searches correlating these indexes. It has been used as a research tool in several researches to single out difficulties in specific mathematics topics or problems, for example in Ferretti and Gambini (2018), or in Ferretti, Giberti and Lemmo (2018). Gestinv allows both a fine grain and a coarse grain analysis of mathematics didactical phenomena and the data can be organized according to the basic contents and the indications of the Italian national curriculum.

To create a consistent framework for our study, it is necessary to combine the potentialities of Gestinv with a theoretical lens that allows us to look into the complexity of the didactical phenomenon that we want to investigate with the database. In the case of this paper our aim is to use Gestinv to observe the behavior of students in algebra, in particular when working with powers.

The learning of algebra is a key research issue in mathematics education, that involves a leap from procedural to relational and general cognitive functioning. Such a change in cognitive perspective is underpinned by the use of semiotic representations that in algebra implies the use of symbolic language intertwined with other semiotic systems.

Duval's (1995, 2008) semiotic approach highlights a specific cognitive functioning in mathematics, due to the special epistemological nature of its objects that do not allow ostensive references. Thinking and learning in mathematics is identified with the coordination of semiotic registers via treatment and conversion. Treatment is a semiotic transformation from a representation into another within the same register and conversion is a semiotic transformation from a representation in one register into another representation in another register.

The inaccessible nature of mathematical objects leads the student in a cognitive paradox that obliges him to identify the mathematical object with its semiotic representations (Duval, 1993). The cognitive paradox can hinder the student's meaning making processes since he is unable to establish the correct relationship between the mathematical object (the signified) and several representations (its signifiers). Conversion is particularly difficult to carry out because there is no syntactic rule that binds the first representation in one register with the second in the other register. In conversion, the pupil ends up with a series of unrelated representations that he is unable to refer to the same mathematical concept. According to Duval, conversion is the key cognitive function that guarantees the conceptual acquisition of mathematical objects.

Treatments instead rest on the structure of the semiotic register that provides the pupil with the syntactic rules to go from one representation to the other via the semiotic transformation. Therefore, we expect that students are able recognize that different representations involved in treatment transformations refer to the same mathematical object. Within this framework our research questions are: Q1: What precise information, regarding powers, can we acquire from a research that implements Gestinv? Q2: Is it possible to collect information that is coherent with solid research findings? Q3: What methodological tools does Gestinv provide?

## Methodology.

Our research methodology intertwines qualitative and quantitative methodologies according to Johnson and Onwuegbuzie (2004) and Iori (2018). In our research design we mixed quantitative

and qualitative methodologies according to the following scheme: QUAL -----> QUAN -----> QUAN+QUAL. From a qualitative point of view our aim was to ascertain higher school students' difficulties in algebra. In particular our focus was on the students' ability to give meaning to the syntactic structure of algebra. Gestinv allowed us to carry out a quantitative analysis based on the INVALSI grade ten mathematics items, selecting the ones with lower scores. Among these we noticed that the management of powers yielded the worst results, in particular the tasks involving treatment operations. At this point we carry out a Quan/Qual analysis that combines our semiotic lens (Qual) with the study of the characteristic curves and the distractor plots (Quan).

In Figure 3 we see an example of our basic tool. On the x-axis are the students' level of competence, measured on the basis of the whole test and on the y-axis are the probabilities of answers to the distractors in function of the level of competence. The solid line represents the curve predicted by the model (characteristic curve) whereas the dotted lines are the empirical results of the test, plotted by deciles. Characteristic curves and distractor plots are an effective quantitative tool to highlight correlations between the students' answers to a specific item according to the basic contents and the indications of the Italian national curriculum, which informs the structure of the INVALSI test.

We point out the fact that we selected items close to the kind of algebra activity usually performed in Italian high schools during the first two years of secondary school. Moreover the items were selected according to the INVALSI theoretical framework, which considers the ability to handle semiotic transformations as one of the basic cognitive processes. We used the functions of Gestinv to choose items that matched our research needs in terms of cognitive processes, mathematical content and learning objectives. We turned out with items that highlight students' difficulties in giving sense to algebraic representations as they undergo treatment transformations. It is important to keep in mind that in Italy students, when learning algebra, are mainly exposed to complicated, heavy, and long algebraic calculations, basically treatments. This is also true for the teaching and learning of powers.

## Results.

The following task was administered in 2017 Mathematics Grade 10 INVALSI test.

You can write the expression  $\left(a - \frac{1}{a}\right)^2$  like:

A. ☐  $a^2 + \frac{1}{a^2} - 2$

B. ☐  $\frac{a^4 + 1}{a^2}$

C. ☐  $a^2 - \left(\frac{1}{a}\right)^2$

D. ☐  $\frac{a^2 - 2a + 1}{a^2}$

**Figure 1: Task in Mathematics Grade 10 INVALSI Test 2017**

This INVALSI test was administered to 540.000 grade 10 students; the results refer to a sample of about 48.000 students representative of the whole population. The task requires to perform a

treatment operation in the algebraic register, applying a well-known identity. As we can see in the following figure (Figure 2), only 34% of the students gave the correct answer; the majority of students who did not solve the task correctly chose option C. This item disproves Duval's claim that conversion is the key semiotic transformation and that treatment supports students in the construction of the correct meaning of mathematical concepts, in this study, powers. All the incorrect options reveal difficulties in the treatment operations and the mathematical meaning is completely lost. For example, option C formally resembles the original algebraic expression but there is no link to the correct mathematical meaning of powers. It is interesting how the students do not rely on the algebraic transformation rules to give sense to their mathematical activity. This item provides a quantitative confirm of qualitative researches that show how treatment transformations can result in a change or loss of meaning (D'Amore, 2007; Santi, 2011). Such researches show that meaning cannot be reduced to the structure of semiotic systems, but it is rooted in the range of social activity, at a personal and cultural level. In absence of a meaningful personal activity, the student, according to the cognitive paradox, interprets the semiotic representations as if they were unrelated mathematical objects, thereby losing the reference to the common mathematical object, even if he can rely on precise transformation rules. Rules and procedures that Italian students have trained over and over again in their algebra classes.

**Figure 2: Results referred to the task in Mathematics Grade 10 INVALSI Test 2017**

As we can see in the following graph (Figure 3), among the various options of incorrect answers, option C is the most frequently chosen at all levels of competence, up to medium-high skill levels. It testifies that this loss of meaning roots in convictions and beliefs that affect even the most competent students.

**Figure 3: Characteristic Curve referred to the task in Mathematics Grade 10 INVALSI Test 2017**

The following task was administered in Mathematics Grade 10 INVALSI Test in the year 2015.

The expression  $a^{43} + a^{44}$  is equal to:

A. ☐  $a^{44-43}$

B. ☐  $a^{43} \cdot (a+1)$

C. ☐  $a^{87}$

D. ☐  $2a^{87}$

**Figure 4: Task in Mathematics Grade 10 INVALSI Test 2015**

In 2015 almost 550000 Grade 10 students performed this INVALSI test, and the national results referred to a sample of 48440 students. As we can see in the following graphs, only a third of Italian students provided the correct answer; among the incorrect options, the most chosen option is C. In option C the exponents of the two powers in the text are summed. Again, this protocol shows a loss of meaning, due to a treatment, when the student goes from the original  $a^{43} + a^{44}$  to  $a^{87}$ . The expression  $a^n + a^m$  puzzles the student who is not able to frame it appropriately in the context of powers, thereby he resorts to the well-known identity  $a^n \cdot a^m = a^{(n+m)}$  which leads to a loss of the original meaning. This result suggests that factoring out the GCF is meaningless to most students, despite the thorough practice in terms of treatment transformations they are exposed to. Meaningless in the sense that they confuse the algebraic representations (signifiers) with the mathematical object (signified) and they are not able to establish the correct semiotic reference to the mathematical object.

**Figure 5: Results referred to the task in Mathematics Grade 10 INVALSI Test 2015**

The Characteristic Curve (Figure 6), shows that, among the incorrect options, Option C is the most chosen at all levels of competence.

**Figure 6: Characteristic Curve referred to the task in Mathematics Grade 10 INVALSI Test 2015**

The following question was in the Mathematics INVALSI test that was administered in Italy in 2012 to all Grade 10 students. Almost 533.000 students performed the test and the results referred to a sample of almost 50.000 Grade 10 Italian students. To answer the task correctly, it is necessary to manipulate the exponents of an algebraic expression with two terms.

The expression  $a^{37} + a^{38}$  is equal to:

- A. ☐  $2a^{75}$
- B. ☐  $a^{75}$
- C. ☐  $a^{37}(a+1)$
- D. ☐  $a^{37 \cdot 38}$

**Figure 7: Task in Mathematics Grade 10 INVALSI Test 2012**

As we can see in the following graphs (Figure 8), only 35% of the students answered correctly. More than 25% of students chose option B, in which the exponent of the power is the sum of the exponents of the power in the text. Also, in this situation, option B is the most chosen incorrect option at all levels of competences (Figure 9). If we compare this item we the former we can see that the behavior of the students is exactly the same both in terms of scores and of its characteristic curves. The combination of the last two items shows how Gestinv provides quantitative and qualitative information that we can compare across time to gain further insight on a teaching-learning phenomenon

**Figure 8: Results referred to the task in Mathematics Grade 10 INVALSI Test 2012****Figure 9: Characteristic Curve referred to the task in Mathematics Grade 10 INVALSI Test 2012****Answer to the research questions.**

A1) At a coarse-grained level, Gestinv highlights rooted difficulties in students facing treatments regarding powers. This is a quantitatively relevant macro phenomenon that persists with the same features across time.

A2) At a fine-grained level, Gestinv provides data that are coherent with solid research findings. In particular, it unveils at a quantitative level the phenomenon of change/loss of meaning due to treatment semiotic transformations. Several studies (D'Amore, 2007; D'Amore & Fandiño Pinilla, 2007; Santi, 2011) have shown that at all school levels, including prospective teachers, also treatment bewilders students who experience a loss or a change of meaning in treatment transformations. The loss and/or change of meaning due to treatment transformations implies that mathematical cognition in general and in particular the algebraic one cannot be reduced to a complex transformation of signs. Meaning is beyond the mere relation sign-object and it is necessary to take into account other basic features that characterize sense-making processes in mathematics. Moreover, data easily available in Gestinv show that this phenomenon also affects students with medium-high levels of competences. Thus teacher's didactical awareness is not only aimed at helping weak students but also the so-called stronger ones, devising an effective didactical transposition and didactical engineering that encompass the complexity of mathematical thinking and learning.

A3) Gestinv is an effective tool that entangles quantitative and qualitative research methodologies. As regards the quantitative approaches, they are based on a statistically significant population. It allows us to provide a quantitative validation of theoretical results, confirmed at a qualitative level. Furthermore, the characteristic curves are a powerful tool to intertwine quantitative and qualitative analyses.

**Conclusions.**

Gestinv implements a new research method that combines quantitative and qualitative approaches. In this study, it allowed us to highlight a macro didactical phenomenon that is quantitatively relevant. Thanks to the combination of the quantitative and qualitative approaches we were able both to frame the students' behavior within an appropriate theoretical framework and provide a statistically based quantitative validation of such a theoretical result.

From an educational point of view, Gestinv shows how the school mathematical practices confirm the research results of mathematics education.

Further research is required to understand if Gestinv, implemented as a research method, is able to single out new didactical phenomena that cannot be framed in the current perspectives and therefore prompts new theoretical research.

# Students' attitudes and responses to pair-work testing in mathematics

Eszter Bóra<sup>1</sup> and Péter Juhász<sup>2</sup>

*Keywords: Pair-work testing, 21th century skills.*

## Introduction

In Hungary, mathematics teachers usually teach every topic separately, one after the other. At the end of each topic the students write a test, these results are the main factors contributing to the final evaluation of a student work during the year. Other popular forms of assessments used daily are short oral individual assessments typically at the beginning of the class, short written tests (between 5-20 minutes) and checking the homework problems (OECD, 2015). There are several problems with these traditional tests taking practices.

First, the problem with the longer, end-of-topic tests are, that they can also contribute to the development of bad studying habits (e.g. last-minute studying, bad time-management), being these tests are often infrequent and their dates are known beforehand.

Second, in general, writing a test is not a perfect option for assess one's understanding of a concept or level of mastery. Since a worrying number of students develop test anxiety over the years, and so, it is hard to tell how well they mastered the given topics. In Hungary there is a surprisingly high level of test anxiety among children (Bodas & Ollandick, 2005). For these reasons, we started to experiment with routines of testing with a novel approach. We want to encourage students to perceive testing situations more like an interesting challenge, as a part of the learning process. With a group of students, we tried pair-work tests. Our reasoning behind this idea is the following: if one of them run out of ideas, the other can help. If none of them has an idea, they can realize the problems are indeed hard and they can try to develop new ideas together. If they fail to solve a problem hopefully they will not attribute it to their own failure, lack of skills, because they see their pairs struggling with it as well. Thus it helps to develop a healthy attribution theory, or mindset to mathematics, and in general, to learning.

An additional factor encouraging us to experiment with this type of test is that collaborative skills are well sought after in the workplaces. Unsurprisingly, according to many researchers the necessary 21th century skills (Voogt, 2012) are: collaboration experience, critical thinking, problem-solving skills. Unfortunately, in Hungary the mathematical educational culture is only started to develop and practice more group working, cooperative techniques in a wider context (Andrews, 2003). So, we think it is important to develop, adopt these cooperative techniques in our local contexts as well.

The novelty of our work is to examine collaboration in a testing scenario in Hungarian mathematics education.

## Our study

In our current pilot study there were four tests: twice students were tested in pairs and twice students were tested individually. We recorded the marks and overall performance of two-two sets of each type of tests. The tests had the same format and length, similar difficulties and recurring topics.

The pairs were randomly selected for the pair-work tests. They did not know beforehand who their partner will be for the test. If the number of students was odd, then the first step was to know which students is willing to work alone.

After the pair-work tests we conducted an online questionnaire. Where we asked the following five questions. What percentage of the test was your contribution? How do you like the concept of writing tests in pair? How would you rate your experience during the test? How did you like your pair before the test? How did you like your pair after the test?

We made an unstructured interview with the teacher about his observations during the test, and about his opinion about the possible long-term impacts of the paired testings.

What are the students' attitudes to paired testing? We can assume from the result of the questionnaire that most student perceived the test as a fair one. We can also assume more confidently, that students have a positive attitude towards paired testing: they rated positively the concept, and they also rated their testing experience positively, despite, as in some cases, their initial not so positive attitude to their partners.

How did students respond to paired testing? Their attitudes towards each other improved. The overall level of paired work was high, the style of writing had more clarity than solo work. According to the teacher's interview, in general, students collaborated intensely but quietly, not disturbing each other.

Given the small sample size and time-frame, further research is needed to determine how paired testing improve collaboration and mastery of skills.

## Classroom assessment tasks and learning trajectories

Eleni Demosthenous, Constantinos Christou and Demetra Pitta-Pantazi

University of Cyprus, Cyprus; [edemos03@ucy.ac.cy](mailto:edemos03@ucy.ac.cy), [edchrist@ucy.ac.cy](mailto:edchrist@ucy.ac.cy), [dpitta@ucy.ac.cy](mailto:dpitta@ucy.ac.cy)

*Abstract. One of the purposes of assessment is to inform the classroom teacher about students' current understanding in order to improve the teaching and learning processes. Learning trajectories present a developmental progression towards increasing understanding of mathematical ideas and are commonly found in curriculum materials to assist teachers in planning instruction. Assessing students' learning along the trajectory could serve as a mediator for adjusting the pacing and the selection of opportunities during the classroom enactment. We propose a framework for designing different types of assessment tasks to elicit evidence about how students respond to the mathematical ideas presented in the trajectory. We illustrate the application of the framework by drawing on a learning trajectory of fraction division for sixth grade students and discuss how the enactment of the trajectory in classroom could be adjusted to students' current understanding.*

*Keywords: Classroom assessment, learning trajectories, assessment tasks.*

### Introduction

Research evidence indicates that assessment could enhance learning, double the speed of learning and reduce the achievement gap between low and high achievers (e.g. Black & Wiliam, 1998; Kluger & DeNisi, 1996). The aforementioned is commonly referred to as formative assessment or assessment for learning. Even though there are differences in the use of these terms (Swaffield, 2011), their focus is on providing feedback to the teacher and student to improve the teaching and learning. In this paper, we use the term “classroom assessment for learning” to highlight that the classroom is the context in which assessment takes place and that the purpose is to elicit evidence about students' current understanding for making instructional decisions to enhance the learning processes.

The learning trajectory can affect and enhance the classroom assessment for learning (Ebby & Petit, 2018; Sztajn, Confrey, Wilson & Edgington, 2012). According to Clements and Sarama (2004), a learning trajectory includes the learning goal, the developmental progressions of thinking and learning, and the sequence of instructional tasks. A learning trajectory takes into account theoretical and empirical data to form a learning route that involves processes to develop increasing sophistication in understanding, which is linked with an instructional sequence (Heritage, 2008; Clements & Sarama, 2004). Classroom assessment could then be closely linked with these cognitive pre-designed learning trajectories as they inform the teacher about the desired learning goal and a progression towards developing understanding. Thus, they can help teachers interpret how students respond to these goals and how they move along the progression path by making informed decisions (Ebby & Petit, 2018).

### Literature review

Assessment tasks could provide information about where students stand regarding the learning trajectory and students' levels of understanding and misunderstanding (Bennett, 2011). The design of assessment tasks has been mainly an issue of discussion for high-stake assessments and standardized tests but it is time to include clear descriptions of the form and key features of classroom assessment in order to enrich the current research base (Kingston & Nash, 2011).

Different types of tasks elicit evidence about various facets of students' understanding. Existing frameworks of assessment tasks rely on categorizations based on the format of tasks or the level of processes students are expected to engage with. Phelan, Choi, Vendlinski, Baker and Herman (2011) categorized tasks into basic computational tasks, partially worked examples, word problems, graphic problems and explanation tasks. Webb, Alt, Ely and Vesperman (2005) and deLange (1999) identified levels of assessment tasks. Webb et al. (2005) suggested that tasks could engage students in recall of information, skills and concepts, strategic thinking, and extended thinking. deLange (1999) categorized tasks into those of reproduction, procedures, concepts and definitions; connections and problem solving; mathematization, mathematical thinking, generalization and insight.

It seems that there is consensus that assessment tasks should elicit evidence from students' engagement with recall procedures to complex reasoning. However, the field lacks a systematic way for making connections between assessment tasks, increasing complexity and learning trajectories. In this paper, a framework is presented towards this aim in order to contribute to the discussion of learning trajectories and assessment for learning. The framework describes types of tasks for classroom assessment for learning which are linked with the learning trajectories aiming (1) to elicit evidence about how students respond to the mathematical ideas presented in the learning trajectory and (2) to inform as well as adjust accordingly the enactment of the learning trajectory as it unfolds in classroom.

Sztajn et al. (2012) mentioned that teachers make sense of students' ideas and respond accordingly by relying on students' reasoning when they follow a learning trajectory since they help teachers identify common misconceptions beforehand. Then, the levels of learning "could serve as reference points for assessments designed to report where students are along the way to meeting the goals of instruction and perhaps something about the problems they might be having in moving ahead" (Daro, Mosher & Corcoran, 2011, p. 29). In addition, it is critical to interpret appropriately the evidence for planning instructional adjustments. The majority of studies, so far, do not elaborate on the possible instructional adjustments based on the evidence from various assessments approaches (McMillan, Venable & Varier, 2013). Instructional adjustments include differentiation for remediation, reteaching using different strategies and changing the pacing of instruction (Hoover & Abrams, 2013).

## **Development of framework**

The framework was formulated by relying on existing categorizations of tasks (i.e., deLange, 1999; Webb et al., 2005), international studies (e.g. TIMSS, PISA) and online resources (e.g. map.mathshell.org). We identified key points of learning, critical features of tasks, ways to capture increasing complexity and then designed tasks for grades 4 to 6. In total, 161 tasks were piloted in real classroom settings during a school year. Based on the feedback from teachers' comments and the coding of students' responses, the types of tasks were refined through several cycles of revisions. In this paper, we present only assessment tasks for a selected learning trajectory for sixth grade.

The framework describes different types of tasks for the purpose of classroom assessment for learning and presents the role of learning trajectories in designing assessment tasks and in planning instructional adjustments. Learning trajectories are foundational since assessment elicits evidence of how students' learning develops towards the expected goal and supports teachers in deciding for their

next teaching actions (Heritage, 2008). A learning trajectory as presented in the curriculum could inform the development of assessment tasks and the evidence from the assessment tasks then shapes the enactment of the learning trajectory in classroom (Figure 1). The fact that teachers in the Cypriot educational context follow closely the learning trajectories as presented in the curriculum materials and particularly in textbooks facilitated the process of designing assessment tasks that were aligned with the learning trajectories by identifying key points in learning. However, the classroom enactment is not expected to be identical to the intended curriculum. Indeed, the evidence from students' responses in the assessment tasks could contribute in adjusting the enactment in classroom to students' ongoing needs.

**Figure 1: Classroom assessment tasks and learning trajectories**

We define a task for classroom assessment to consist of a single request of what students are expected to do and the necessary information to respond to that request. Three different types of tasks were formed and two task features were selected. Table 1 presents the three types of tasks with their respective description. The different tasks aim to elicit evidence regarding students' progression along the learning trajectory and be aligned to the increasing expertise and sophistication as expected by the trajectory. These tasks are not intended to be seen as consecutive and linear steps of learning (e.g., it is not assumed that necessarily “apply and connect” tasks will be used after “recall and reproduce”). These tasks could be used in classroom according to how the learning trajectory unfolds and inform of the ways students develop increasing expertise.

Type of Task	Description of Tasks
Recall and Reproduce	Students are able to respond to these tasks because they can use taught procedures and technical skills.
Apply and Connect	Students are able to respond to these tasks because they can apply the mathematical ideas in various contexts and make connections between representations and mathematical ideas.
Reflect and Generate	Students are able to respond to these tasks because they can investigate mathematical ideas, structures and contexts, and develop their own mathematical products.

**Table 1: Types of classroom assessment for learning tasks**

Familiarity and complexity are two features that characterize the tasks. The familiarity of the task is determined by students' previous experiences with the requests of the task and the information provided. The complexity of the task is determined by (a) the number of steps to complete the assessment task, (b) the amount and nature of information that students need to handle, and (c) the possible deviations that alter the complexity according to the mathematical topic (e.g. the place of the unknown in an equation, the choice of numbers).

## Application of the framework

In this paper, we discuss the application of the framework to design tasks for a learning progression on fraction division, which serves as the context to present examples of the three different tasks for assessment for learning. Fraction division was selected since on one hand it is not a difficult topic when students work only procedurally to invert and multiply. On the other hand, it is conceptually demanding since fraction division could be represented using various ways and connected with other mathematical ideas (Li, Chen & An, 2009).

There are different approaches in the learning trajectories in textbooks around the world (e.g., Li et al., 2009). Only the trajectory found in the Cypriot curriculum materials is presented since it shaped the design of assessment tasks. This trajectory is not presented as an exemplary one but rather as a medium to exemplify the types of assessment tasks, to illustrate how the increasing sophistication in understanding could be captured and to discuss possible instructional adjustments. The selected trajectory is designed to engage students first with whole numbers divided by fractions by making links with quotative division of whole numbers. Then, students are engaged with fractions divided by whole numbers by making links with partitive division of whole numbers. Afterwards, they are introduced to fractions divided by fractions, where again the quotative division appears and they engage also with division of mixed numbers. Students are expected to have the opportunity to learn different procedures (i.e., invert and multiply, convert to fractions of common denominator and divide the numerators), represent fraction division using number line and area models, interpret representations, and solve word problems.

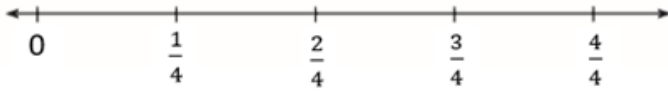

The first type of task aims to assess whether students can reproduce the procedure of fraction division. The procedure is expected to have been taught and practiced. Hence, students would have extensive familiarity. Figure 2 presents an example of “recall and reproduce” tasks. These are different mathematical expressions in order to identify which of these students can complete fluently and flexibly. The last two expressions have increased complexity due to the position of the unknown. This example consists of expressions with different number characteristics and it is not intended to present a step of the instructional sequence but a medium for capturing increasing understanding.

Find the unknown $v$ .	
(a) $6 \div \frac{3}{4} = v$	(b) $\frac{3}{10} \div 5 = v$
(c) $\frac{1}{3} \div \frac{1}{6} = v$	(d) $2\frac{5}{6} \div 1\frac{1}{2} = v$
(e) $1\frac{1}{3} \div v = \frac{2}{3}$	(f) $v \div \frac{1}{4} = \frac{4}{5}$

**Figure 2: Example of “Recall and Reproduce” tasks**

The second type of assessment tasks intend to assess whether students understand the underlying mathematical concept, in this case, the way in which fraction division could be interpreted and represented. It is anticipated that this type of task will bring to the surface students’ reasoning and misconceptions. Figure 3 shows examples of “apply and connect” tasks. Students are asked to represent the fraction division using an area model and a number line. In the first case, students would need to interpret the fraction division as “ $\frac{3}{4}$  divided by 2” and represent it (e.g., divide the rectangle

in 4 equal stripes, shade 3 out of the 4 and then divide the shaded area into two equal regions). In the second case, students would need to interpret the fraction division as “how many  $\frac{1}{4}$ ’s are in  $\frac{3}{4}$ ,” and represent it (i.e., draw three jumps of  $\frac{1}{4}$ ). Deviation to the complexity of the tasks could be achieved without providing the area model and the number line or asking students to provide more than one representation of the mathematical expression (e.g., verbal and pictorial). The last example is a word problem in which students would not only need to identify which procedure to pursue but also to interpret and communicate their thought process.

<p>Represent the mathematical expression using a rectangular model and find the quotient.</p> $\frac{3}{4} \div 2 =$ <div style="margin: 10px 0;">  </div>
<p>Represent the mathematical expression on the number line and find the quotient.</p> $\frac{3}{4} \div \frac{1}{4} =$ <div style="margin: 10px 0;">  </div>
<p>Mr. Apostolos has a piece of wood of <math>\frac{5}{6}</math> m length. He wants to cut it into equal pieces of <math>\frac{1}{8}</math> m. Explain the way in which Mr. Apostolos can work to find beforehand whether it is possible to make 7 such pieces.</p>

**Figure 3: Examples of “Apply and Connect” tasks**

Students are expected to have worked on representing fraction division using a variety of representations and solving word problems. Hence, the requests of the tasks would be familiar to the students. However, depending on the given context of representation and word problem, students would need to decide how to apply the procedure of fraction division and how to interpret it.

The third type of assessment tasks intend to assess whether students can investigate independently mathematical ideas, structures and contexts, and develop their own mathematical products. For example, students could engage in evaluating arguments, generating justifications, forming examples and non-examples. Students are expected to have limited familiarity with the request of the tasks in order to engage in generating an idea instead of recalling it. Figure 4 presents examples of “reflect and generate” tasks. The first task asks students to generate a word problem based on the given mathematical expression. Students are anticipated to have had opportunities in solving word problems but they are now asked to formulate their own word problem by taking into account the given numbers and an appropriate real life situation. The next task, which was adapted from Askew et al. (2015), presents a statement and students are asked to explore whether it is always true, sometimes or never.

Students would need to compare the quotient and the dividend in different cases of numbers (e.g., division of two integers, division of two fractions).

Write a word problem that corresponds to the mathematical expression $\frac{6}{9} \div \frac{1}{3}$ .
Marios says: “When I divide two numbers, the quotient is always smaller than the dividend” Do you think that this is always, sometimes or never true? Explain.

**Figure 4: Examples of “Reflect and Generate” tasks**

A less complex task could be designed by asking students to complete the description of a word problem based on a given mathematical expression while a more complex task could ask students to write a word problem for a mathematical expression consisting of two operations (e.g.  $5 + (\frac{6}{9} \div \frac{1}{3})$ ). Another option is to modify the nature of the information by reducing the complexity such as “Find the cases for which the division of two numbers gives a quotient larger than the dividend”. In this way, students would need to identify cases of numbers that confirm the statement instead of exploring all possible cases of numbers to decide whether Marios’ argument holds true in all, some or none of these cases.

## Discussion

The framework aims to contribute to the discussion about how classroom assessment could be linked with learning trajectories (e.g., Ebby & Petit, 2018; Heritage, 2008). Different types of tasks were formed based on the pre-designed trajectory in curriculum materials that aim to elicit evidence about students’ understanding along the increasing expertise of the learning trajectory in order to make informed decisions of how the enactment of the learning trajectory in classroom could be adjusted. Hence, we rely on students’ understanding to discuss about teachers’ instructional adjustments.

The adjustments elaborate on differentiation, reteaching and changing the pace of instruction (Hoover & Abrams, 2013). Students’ responses to “recall and reproduce” tasks could inform the classroom teacher whether students reproduce the procedure of dividing fractions correctly. If students use the procedures incorrectly (e.g. invert the dividend instead of the divisor and multiply), the teacher might need to provide more opportunities in reteaching the procedure and in using other procedures (e.g. converting into like fractions) to develop understanding. If students complete incorrectly the last two mathematical expressions (in which the place of the unknown differs), then the teacher might make explicit links between division of whole numbers and division of fractions. If students seem to make minor arithmetical mistakes (e.g. in converting mixed numbers to improper fractions), then either they face difficulties with previously taught mathematical concepts or they need further practice. Hence, along the enactment of the learning trajectory in classroom, more time and relevant opportunities could be planned. The evidence elicited from “apply and connect” tasks could indicate whether students are facing difficulty in making sense of fraction division, in using different representations, in identifying fraction division in various contexts and even making connections with fraction multiplication. If students find difficulties with the area model and the number line, then either more opportunities are needed to make sense of what fraction division means or more

opportunities are needed with the particular representational formats (e.g. by corresponding various fraction division expressions with their respective representations). If students solve the problem incorrectly (e.g. they mention that it is possible to make 7 such pieces), then either more opportunities are needed to address previously taught concepts (e.g., converting into like fractions) or more opportunities to develop understanding of how fraction division could be interpreted. The “reflect and generate” tasks could inform teachers whether students could extend their understanding of mathematical ideas and exhibit higher-order thinking. If students find difficulties in writing a word problem that corresponds to the given mathematical expression, then students might need further opportunities to reflect on the structure of relevant word problems and opportunities to write word problems using for example integer numbers. Students who are not able to respond fully or complete at all the last task might need further opportunities that engage them in reflecting about the structure of numbers and to develop arguments that justify or refute a statement.

Decisions about instructional adjustments would also be regulated by the number of students facing constraints and time limitations. The number of students will determine whether adjustments will involve the whole class, groups of students or individual students. The teachers’ role is quite demanding in making decisions for the pacing of instruction and for the selection and amount of learning opportunities. Particularly, teachers find most difficult the process of using assessment information to plan instructional actions (Heritage, Kim, Vendlinski & Herman, 2009) while some teachers may not even use the information to adapt their instruction (Zhao, Van den Heuvel-Panhuizen & Veldhuis, 2017).

The presentation of the framework, in this paper, is limited to its application in the design of assessment tasks based on a learning trajectory for fraction division. The framework could be validated and further refined by developing tasks for other grade levels. Further empirical evidence could provide insight into the potential and limitations of the framework from its application in real classroom settings. Further research could also explore what kind of evidence is purposeful for teachers to be elicited from assessment tasks and how decisions about instructional adjustments could be planned to move students towards increasing expertise along the learning trajectory.

# Diagnosis of basic mathematical competencies in years 8 and 9

Christina Drüke-Noe<sup>1</sup> and Hans-Stefan Siller<sup>2</sup>

<sup>1</sup> Pädagogische Hochschule Weingarten, Weingarten, Germany; druekenoe@ph-weingarten.de

<sup>2</sup> Universität Würzburg, Würzburg, Germany; hans-stefan.siller@mathematik.uni-wuerzburg.de

*In this paper we present a newly developed test with easy tasks which assesses basic mathematical competencies that are essential for vocational training. This test is used in years 8 and 9 in Germany. From both a content-oriented and a process-oriented perspective, preliminary test results reveal a substantial lack of these competencies in all academic tracks, and differential effects can be found with respect to year and class that need to be examined beyond curricular analyses.*

*Keywords: mathematics tasks, diagnostic test, assessment, basic competencies, vocational training.*

Many professions require at least basic mathematical competencies to understand or to implement work processes, and such competencies are a prerequisite to successfully begin vocational training. Consequently, in mathematics these competencies should have been acquired beforehand by means of working on tasks. So far and especially in international comparative tests, the relation between tasks, basic mathematical needs and vocational training has hardly been examined as the few initial approaches to adult education primarily focus on social participation and necessary mathematical understanding. In this paper we present our task-based approach to testing secondary students' basic mathematical competencies and raise ideas how to support these students adequately and in time.

## The role of tasks in Mathematics

Especially in Mathematics tasks are essential and thus they are being used from various perspectives in both research and teaching. In any case they require engagement with a certain mathematical content (e.g. Christiansen & Walther, 1986), and they are understood here as orally or written set assignments to students to carry out a subject-oriented activity (Drüke-Noe et al., 2017).

In research, tasks can serve as documents of mathematics instruction. This applies e.g. to the project COACTIV in which tasks are used not only to assess teachers' professional knowledge but also to get insight into the level of cognitive activation potentially realized in teaching or assessing mathematics (Kunter et al., 2013). Tasks also form the linking element between curricular standards and the professional knowledge of teachers on the one hand and the aimed-at knowledge, skills and competencies of students on the other hand (Neubrand, Jordan, Krauss, Blum, & Löwen, 2013).

Furthermore, tasks are essential in tests to assess the achievement of learning goals. For this purpose, oral and especially written tests are regularly set in Germany. These tests, which are either set internally or externally, comprise a range of tasks of a certain cognitive demand to examine competencies either formatively or summatively. Due to their backwash effect on teaching as well as their impact on the students' further educational career, centrally set external examinations at the end of various stages of education are quite prominent examples of summative written tests. Interestingly though, in several European countries as well as in different federal states of Germany such centrally set exams are often of a relatively low level of cognitive demand and cover only a limited range of competencies (Kühn & Drüke-Noe, 2013; Drüke-Noe & Kühn, 2017). This also applies to internally

written mathematics tests in Germany, so called class tests (Drücke-Noe, 2014). From a normative perspective, however, adequate compilations of tasks in tests are crucial as they “summarize the core components of an instructional unit and ultimately specify the level of mathematical achievement that teachers require” (Neubrand et al. 2013, p. 128) and thus make social expectations transparent for both teachers and students.

It can be concluded that tasks are “actively configurable content-related and didactic elements that serve to structure mathematics instruction” (Neubrand et al., 2013, p. 126; see also Zaslavsky, 2007, p. 434) that “provide the basis for students’ cognitive activities” (Neubrand et al., 2013, p. 127) and therefore play an essential role in teaching, learning and assessing mathematics.

## Tests and Basic Competencies

In Germany, as a consequence from only mediocre results in international comparative studies like e.g. TIMSS and PISA, educational standards have been implemented in almost all subjects in the last fifteen years. In the course of this, the focus of attention shifted towards regular formative examinations of learning goals and competencies, and several centrally set formative tests were introduced nationwide in Germany that serve as diagnostic instruments. These tests are designed on the basis of the German Educational Standards and are in accordance with the standards’ conception. Therefore, their tasks cover all five content strands (quantity, measuring, space and shape, change and relationships, uncertainty and statistics), all six competencies (argumentation, problem solving, modeling, use of representations, working technically, communication) and all three levels of cognitive demand (low, medium, high). Two different kinds of tests are set: A first kind is compulsory comparative tests which are set in the years 3 and 8 (9-year- and 14-year-olds) which are administered as well as corrected within schools. The test results are to provide diagnostic information in which areas both teaching and learning should be improved to prepare students for a successful completion of compulsory education one or two years later at ISCED-level 2. A second kind of tests is centrally set every six years in the years 4 and 9. Its conception is standard-based, too, but this nationwide test is only taken by a representative sample of students and its results are only used by the education administration to monitor the school system with respect to the successful achievement of the educational standards. For both years 4 and 9 and especially for the latter one results reveal regularly that on average one quarter of all German students miss minimal educational standards (Pant et al., 2013). Very similar findings come up in a German longitudinal study on Bavarian secondary students of different school tracks (vom Hofe & Hafner, 2009) as well as in regular international studies like PISA (e.g. Neubrand & Neubrand, 2004).

To summarize, there is much empirical evidence for the mathematical achievement of year 9-students that firstly implies that 16-year-olds, who leave school at the end of lower secondary education and are about to enter a phase of vocational training, lack substantial basic skills such as a reflective use of knowledge and abilities. Secondly, these students presumably lack not only the basis for an understanding of routines beyond their mechanical application but also knowledge of problem solving activities. Consequently, it seems not only necessary to diagnose such basic competencies well beforehand but also – which is even more important – to support these low-achievers in time both on a class-level and individually, too. More efforts need to be taken so that in the future less students fail

minimal standards since a successful achievement of at least minimal standards is a precondition to successfully begin (and complete) a vocational training after the end of year 9 (or year 10).

These necessities form the basis of our task-based project „Diagnostic scaffolding of basic mathematical competencies for vocational training“. In this project we assess basic mathematical competencies well before students leave school. We test entire classes and can provide teachers with quantitative and qualitative feedback on the test results. Teachers can use this feedback to support their students to better achieve basic competencies by the end of compulsory education.

## **Basic Competencies and the Start of Vocational Training**

Based on the German Educational Standards we designed a test that only assesses basic mathematical competencies relevant for vocational training. As an adequate selection of tasks for such a test substantially relies on both an understanding of basic competencies as well as of what is necessary to successfully start a vocational training, we briefly outline essential elements of both here.

In Germany, there are different empirical and normative approaches to defining basic competencies for the end of compulsory education, which is usually the end of lower secondary education irrespective of successfully obtaining a formal school leaving certificate. However, there is no consensus as to whether basic competencies characterize what is really necessary to be prepared for a life as a citizen, for a successful start and/ or completion of a vocational training. It is equally diverse who defines basic competencies; is it teachers or researchers or those who continue working with these students after a certain stage of education? Some other task-based approaches to defining basic competencies which are relevant for our one and only focus on the end of lower secondary education are briefly outlined in the following: One primarily normative concept by Sill and Sikora (2007) considers empirical results from national comparative studies and defines basic mathematical competencies needed for further education, everyday life and society. It comprises three so-called competency levels that distinguish whether certain knowledge and abilities should be immediately and automatically applicable or be easily re-activated or be only exemplary and episodal. A second concept is essential for our approach as it is explicitly based on the German Standards. It combines a normative with an empirical approach and defines basic mathematical competencies as those

which all students of all educational levels must at least and permanently have at the end of compulsory education. These competencies are a prerequisite for sovereignly mastering everyday life and actively participating as politically mature citizens in social and cultural life. These competencies are equally a prerequisite for a successful and promising start into a vocational training and a pursuance of one's profession. Those who do not have these basic competencies will presumably not sufficiently be able to get along in these situations without help. These students must timely and particularly intensively be supported (Drücke-Noe et al., 2011, p. 8).

A third German and predominantly empirical approach is the “Model of Competency Levels for the Educational Standards for a qualified school leaving certificate at the end of year 9 and at the end of year 10” which was passed by the Standing Conference of the Ministers of Education and Cultural Affairs. Based on results from several large scale studies and applying probabilistic test theories which relate task difficulties to students' abilities, this model is based on a competency scale which

distinguishes six competency levels. These levels describe students' abilities on the basis of task properties. The lowest two levels, which we only focus on here, define the minimal standard as a set of competencies that all students must have achieved by the end of a certain educational stage. Students at or below this minimum standard can only comprehend or apply the most simple standard argumentations or problem solving activities, use simple models or well-known visualizations, apply one-step routines or extract single pieces of information from simple texts (Kultusministerkonferenz, 2011, p. 29ff).

Several other international approaches to basic mathematical competencies also relate structural errors to procedural processes: Brown and Burton (1978) already do so in their "Diagnostic Models for Procedural Bugs in Basic Mathematical Skills" and stress the close relation between basic skills, procedural and conceptual knowledge. In his analyses of structural errors with respect to procedural knowledge Wu (1999, p. 1) stresses that "in mathematics, skills and understanding are completely intertwined". Ritter-Johnson, Siegler and Alibali (2001, p. 346) equally claim that "conceptual and procedural knowledge influence one another [...] and develop iteratively, with increases in one type of knowledge leading to increases in the other type of knowledge".

Consequently, a traditionally rather content-focused perspective on teaching (and testing) ought to be widened to a more comprehensive one which considers both content and processes not only when putting curricular regulations into practice but also when teaching and testing basic competencies which – amongst others – are necessary to work successfully on mathematics tasks. With respect to vocational training, Weißeno and colleagues (2016, p. 3) additionally point out that "mathematical skills play an important role in developing job specific competencies in a number of occupations that require intermediate qualifications." Thus, learners do not have to be experts in the field of mathematics, but they must be able to implement the necessary basic skills, as well as be able to critically reflect upon and to apply processes in the course of solving tasks to correspond with the concept of "Higher General Education" as developed by Fischer (2001).

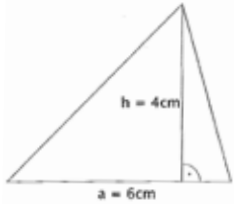

In our project, we designed a task-based test to assess students' basic mathematical competencies relevant for vocational training. Due to our test conception we can derive information on these competencies from both a content- and a process-oriented perspective. Furthermore, this information and deeper test analyses allow us to deduce a specific feedback to support teachers and students.

## **Test Conception and Task Features**

To both evaluate basic competencies and consider a prospective ability to take up vocational training, our test addresses students who aim at getting a qualified school leaving certificate at the end of year 9 or at the end of year 10 (ISCED-level 2). To allow for sufficient time for compensation before leaving school, both versions of this test (see below) can be taken well before, i. e. in year 8 (14-year-olds) and/ or in year 9 (15-year-olds) and can be set in all school tracks.

Since the test's conception is based on the Educational Standards, it covers all five content strands, all six competencies and all three levels of cognitive demand (see Table 1). All tasks were selected correspondingly and thus allow analyses from a content- and a process-oriented perspective. Based on cognitive analyses we can describe the content addressed and the competencies needed when

solving a task, which we briefly outline below by means of three examples. As only basic competencies are to be assessed, only relevant content areas of the curriculum of the preceding years 7 and 8 are tested. This curricular validity has been approved by experts. Almost all tasks are presumed to be empirically easy (i. e. at least 80 % correct answers are expected) as they were developed in accordance with characteristics of the two lowest levels of the competency level-model (KMK, 2011). However, from our perspective relevant basic competencies not only comprise the ability to apply certain routines and procedures to show *how* something works but also to use them critically and/ or to explain *why* something works: Therefore, we intentionally included some presumably empirically more difficult tasks in the test and only for these we anticipated less than 80 % correct answers.

<p>Calculate the area of the triangle.</p> 	<p>Use the illustration to explain why the area of a parallelogram is determined by applying the rule <math>\text{Area} = \text{Length of Base} \cdot \text{Height}</math>.</p> 	<p>Heike's savings book shows 180 €. The interest rate is 2 % per annum.</p> <p>Calculate the amount of interest after 4 months.</p>
------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------

**Figure 1: The tasks “Triangle” (left), “Parallelogram” (middle) and “Savings book” (right)**

Three tasks (see Figure 1) are to illustrate our approach: The task „Triangle“ is cognitively easy and it tests *how* something works. The representation immediately leads to a procedure to calculate the area by means of the given lengths of the triangle's base and height. This task ought to be empirically easy as calculating the area of this elementary figure requires just one step with small numbers. The task “Parallelogram” represents those that test *why* something works. The rule to determine the area of this quadrilateral is explicitly named. Using the representation students need to develop a strategy to explain *why* the area can be calculated by means of this rule. According to the competency level-model (KMK, 2011) it must be assumed, though, that this is no empirically easy task as it requires an argumentation. In the task “Savings book” students must initially extract relevant information from a simple text (communication) to then design a strategy and apply a basic mathematical model to calculate the amount of interest (problem solving, modeling, working technically).

Test version	Competence						Level of cognitive demand		
	Argumentation	Problem solving	Modeling	Use of Representations	Working technically	Communication	low	medium	high
<b>B</b>	4	2	4	11	9	7	3	11	1
<b>E</b>	8	7	5	9	8	12	2	11	2

**Table 1: Numbers of tasks that require one or more of the six competencies and numbers of tasks of the given level of cognitive demand**

The two test versions (B: basic version, E: extended version) comprise 15 tasks each with three tasks per content strand that all require open answers. Eight tasks are identical in both versions and almost all the remaining seven ones are parallel versions of each other which differ either only as regards their presumed task difficulty or as regards the track-specific curriculum. The students have

45 minutes to work on the test, and they may only use pens, a ruler and a device to measure angles. Before the test was finally used, it was tried and tested beforehand and improved further.

By means of a coding scheme and applying a dichotomous coding with double digits, different types of correct, partly correct or wrong answers are identified. Further analyses of the test results allow us to provide teachers with quantitative feedback (charts on types of answers with respect to content strands) and with qualitative feedback on missing basic competencies. Thus, this diagnostic test with its combined content- and process-oriented design and the subsequent detailed feedback may not only close a gap PISA leaves but also provides teachers with class-specific information on (missing) basic competencies of prospective school leavers. Teachers can then use this detailed information to develop suitable interventions to better support their students to acquire basic competencies.

## Sample and preliminary results

The test was set to a non-representative sample of students (N=367) in 16 academic and nonacademic classes (see Table 2) from two German states (Baden-Württemberg, Rhineland-Palatinate). The test took place at the beginning of the second semester in the school year 2016/17.

Test version	Academic track	Nonacademic track
B	---	Baden-Württemberg: 2 classes in year 8 (N=52), 2 classes in year 9 (N=45)
E	Rhineland-Palatinate: 2 classes in year 8 (N=52), 8 classes in year 9 (N=189)	Baden-Württemberg: 2 classes in year 9 (N=29)

**Table 2: Sample of classes and students that took the diagnostic test**

In accordance with the standard-based test conception we present preliminary findings firstly from a **content-oriented perspective** and then from a process-based one. Irrespective of track and year, hardly one quarter of all students (23 %) correctly solved both tasks on the area of elementary figures (see Figure 1), and almost equally many students (26 %) solved none of these two correctly. It is interesting to note that the task „Triangle“, which rather focuses on procedures (knowing *how*), was solved considerably better by students from the nonacademic track (nonacademic track: 76 %, academic track: 64 %). However, considering both this task's features and the predominance of routines in Germany, a much higher percentage of correct answers could have been expected. Less surprising, far more students from the academic track were able to solve the task „Parallelogram“ (nonacademic track: 6 %, academic track: 42 %) which rather focusses on understanding (knowing *why*). As expected, in both tracks students of year 9 solved both tasks better than those in year 8 but from a content-based perspective the overall results of both tasks are rather astounding as the area of such basic figures is an integral part of every curriculum. Error analyses reveal that students typically fail when distinguishing formulae (here: area of a rectangle and that of a parallelogram) or when explaining a rule (see “Parallelogram”) although it is explicitly given here.

For analyses from a **process-oriented perspective** we focus on modeling here. Detailed analyses of the students' work rely on steps of the modeling cycle by Blum and Leiß (2005). As expected and irrespective of track and year, in all six modeling tasks students primarily find it difficult to understand the real situation and then to constitute a situation model. Furthermore, validating a result

proves to be another difficult step even for students of the academic track. Surprisingly, in year 9 only 39,2 % of the students in the academic track solved “Savings book” correctly (non-academic track: 20,7 %) and many typically failed when validating an even obviously wrong result like e. g. an annual amount of interest of 9000 €. Based on detailed analyses of this kind we provide teachers with both quantitative and qualitative feedback on their students’ basic competencies. The qualitative feedback is based on cognitive analyses of all tasks which serve as a basis for class-specific descriptions of the most frequent mistakes per task. All these descriptions help to characterize existing and lacking basic mathematical competencies within each class and can support teachers in their successive work.

## Summary and Implications

The preliminary results of our test correspond with results from representative national and international studies. Beyond this, our test which is curricular valid *and* addresses basic mathematical competencies relevant for vocational training once more highlights a discrepancy: Though these competencies are broadly considered to be essential, considerably high proportions of students can neither use nor apply them and thus lack crucial preconditions to successfully start a vocational training and succeed in their later professional careers. This leaves many things to do: From both a scientific and a diagnostic perspective, further analyses beyond curricular ones are necessary to explain unexpected differential effects as regards tracks, years and classes. Secondly, far greater efforts are needed to turn *all* students into citizens of age (cf. Fischer, 2001) and to provide them with basic mathematical competencies. We are currently developing adaptive lesson material to be implemented (and evaluated) in teaching. This material specifically addresses students’ typical difficulties as regards acquiring and keeping basic mathematical competencies. The material aims at supporting students to better solve tasks on *how* something works as well as those on *why* something works, which means that all students should be able to write down argumentations or to validate results to name just a few examples. Last but not least it will be necessary to improve not only the tasks but also the kinds of feedback we provide the teachers with.

# Assessment and argumentation: an analysis of mathematics standardized items

Rossella Garuti<sup>1</sup> and Francesca Martignone<sup>2</sup>

<sup>1</sup>INVALSI, Rome, Italy, [rossella.garuti@libero.it](mailto:rossella.garuti@libero.it)

<sup>2</sup> Università del Piemonte Orientale, Alessandria, Italy, [francesca.martignone@uniupo.it](mailto:francesca.martignone@uniupo.it)

*In this paper, after a brief description of Italian National Guidelines and Evaluation System, we present and analyze two examples of standardized items focused on argumentation. The qualitative analysis is carried out by using theoretical lenses coming from studies about mathematical argumentation: in particular, we use Toulmin's model to identify common features in the structure of these standardized items. The first results of our analysis give us the elements to reflect on the multiple-choice items structures that could be used for identifying specific aspects about argumentation and for assessing students' skills.*

*Keywords: Assessment, argumentation, standardized tests.*

## Introduction

Since many years, mathematics education research has dealt with teaching and learning argumentation and proof (Hanna, 2007). The importance of argumentation in mathematics education was perceived also at the institutional level and has led to important changes in the orientation of different countries curricula (from primary to secondary school) all over the world.

Also, in the frameworks of the main international surveys, as IEA TIMSS and OECD PISA, argumentation is an important milestone. In the Mathematics Framework of IEA TIMSS 2019 (IEA, 2017) one of the three cognitive domains (*reasoning*) is described as:

Reasoning mathematically involves logical, systematic thinking. It includes intuitive and inductive reasoning based on patterns and regularities [...]. Reasoning involves the ability to observe and make conjectures. It also involves making logical deductions based on specific assumptions and rules, and justifying results. (TIMSS 2019 Mathematics Framework, p. 24)

As regards OECD PISA survey, in the recent version of the mathematical framework, we read:

Mathematical literacy therefore comprises two related aspects: mathematical reasoning and problem solving. Mathematical literacy plays an important role in being able to use mathematics to solve real-world problems. However, mathematical reasoning also goes beyond solving problems in the traditional sense to include making informed judgements in general about that important family of societal issues which can be addressed mathematically. It also includes making judgements about the validity of information that bombards individuals by means of considering their quantitative and logical implications. (PISA 2021, Mathematics Framework, First draft, p. 10)

In this paper we examine how Italian mathematics standardized tests try to assess specific aspects related to argumentation skills: we analyse two items selected from grade 5 (primary school) national standardized tests. We use theoretical lenses taken from research in mathematics education in order

to highlight the argumentation features that these two standardized items focused on. Our reflections are grounded in the studies on argumentation processes carried out by some Italian researchers (Boero, Garuti & Lemut, 2007; Boero, Douek, Morselli & Pedemonte, 2010; Arzarello & Sabena, 2011).

### **Italian National Guideline and standardized tests**

In the last ten years, new Italian National Guideline (NG) for the first cycle of instruction (i.e. pre-primary, primary and middle school) have been proposed by the Ministry of Education (Ministero dell'Istruzione, Università e Ricerca, MIUR). For primary and middle school (grades 1 to 8), the NG were first published in 2007 with the latest version arriving in 2012 (MIUR, 2012). Italian legislation does not lay down a strict curriculum, but it indicates the goals for competence development at the end of grades 3, 5 and 8.

Some of these goals refer explicitly to the argumentative skills that students should acquire:

[the student] constructs reasoning by formulating hypotheses, by supporting his/her ideas and by dealing with others' points of view (grade 5, end of primary school, MIUR 2012, p. 50, translation by the authors)

[the student] produces arguments based on the theoretical knowledge acquired [...] [the student] supports his/her beliefs by choosing examples and counterexamples and by using concatenations of claims; [the student] agrees to change his/her opinion recognizing the logical consequences of a correct argument" (grade 8, end of middle school, MIUR 2012, p. 51, translation by the authors).

The Italian Ministry of Public Education has established the standardized assessment of the Italian educational system, and commissioned the INVALSI ([www.invalsi.it](http://www.invalsi.it)) to carry out annual surveys nationwide to all students in the second and fifth grades of primary school, grade 8, and high school (grades 10 and 13). INVALSI is a research institute with the status of legal entity governed by public law. INVALSI carries out periodic and systematic checks on students knowledge and skills (about reading comprehension, grammatical knowledge and mathematical competency), and on the overall quality of the educational offers from schools and vocational training institutions; in particular, it runs the National Evaluation System (SNV). The INVALSI standardized tests were created for system evaluation and this is their primary purpose. The statistical representative sample comprises approximately 30,000 students (with tests administered under controlled conditions). Moreover, the tests are administered at census level and students results are provided to each school institution. The SNV Framework defines what type of mathematics is assessed by the SNV tests and how it is evaluated. It identifies two dimensions along which the items are built: the mathematical content, divided into four major areas (Numbers, Space and Figures, Relations and Functions, Data and Uncertainty), and the mathematical processes involved in solving the items (Knowing, Problem Solving, Arguing and Proving). These dimensions are closely and explicitly related to the goals for competence development of NG. The framework adopted by SNV assessment includes aspects of mathematical modelling as in PISA survey (Niss, 2015), and aspects of mathematics as a body of knowledge logically consistent and systematically structured, characterized by a strong cultural unity (Arzarello, Garuti, & Ricci, 2015). The INVALSI tests are designed by expert teachers, educational

and disciplinary researchers, statisticians and experts of the school system. (Garuti & Martignone, 2015; Garuti, Lasorsa, & Pozio, 2017).

### **Argumentation in INVALSI tests**

As stressed before, taking into account the NG suggestions, INVALSI tests aim to assess also argumentation skills. Therefore, our research questions are: which aspects related to argumentation skills can be assessed by a standardized test? And in which way? These are very general questions that we faced starting from a more specific investigation about which elements were taken into account in the construction of some INVALSI argumentative items.

In a INVALSI booklet there are approximately 40-50 items and about 10% of these are about argumentation. A standardized test cannot assess all the argumentative skills quoted in the NG (e.g. formulating hypotheses or exploring a problem situation in order to produce conjectures), but it can propose tasks that ask students to support his/her statements, to show examples and counterexamples, and to recognize the logical consequences of a correct argument. In the SNV framework the limits of standardized tests in the assessment of mathematical competencies, particularly with regard to the argumentative skills, are well explained, but it is also clear that some aspects of this capability can be assessed. For example, by means of items that ask to choose the correct answer and the right justification of it among the options proposed, or to produce and justify the answer. In INVALSI tests, two item-format types are used to assess the argumentative skills: open constructed-response items and selected-response (multiple-choice) items. The first may ask the student to explain how the answer was reached or to justify the answer of a given statement; the second requires to select one response among a number of options.

In this paper we analyze two multiple-choice items selected from grade 5 tests. We joined the groups of teachers and experts, who produced the INVALSI tests, therefore we can argue about the choices made during items productions. These choices are the results of discussion in which Mathematical Knowledge for Teaching (Ball, Thames, & Phelps, 2008), the experiences developed in the classrooms, and knowledge about educational research studies merged.

Any discourse cannot be accepted as an argumentation, “[...] a reason or reasons offered for or against a proposition, opinion or measure” (Webster Dictionary), and may include verbal arguments, numerical data, drawings etc. Argumentation can indicate both the process which produces a logically connected discourse about a given subject and the text produced by the process (Douek, 2007).

In order to describe the structure of mathematics argumentations, as texts produced, different studies use Toulmin’s model (1958). In the next paragraph we show some interpretative tools proposed by this model.

### **An interpretative tool for the argumentation structure**

Toulmin’s model (1958) has been used for the analysis of arguments in mathematics education (Pedemonte, 2007) as a tool to analyses structural features of mathematics argumentation both with pre-service teachers (Arzarello & Sabena, 2011) and primary students (Douek & Scali, 2000). Many studies report the limitations of this model in order to analyze mathematical argumentation (Nielsen 2011), in particular to study the dialogical and dialectical elements of verbal interaction that take

place in the classroom. The “argumentation” is much more complex than the arguments that make it up, but Toulmin’s model can be used to identify the argument structure, in particular to break down arguments into their constituent parts. In Toulmin’s basic model an argument comprises three elements: the Claim (C), i.e. the statement; the Data (D), i.e. the data that justify the claim C; and the Warrant (W), i.e. the inference rule which allows data D to be connected to claim C.

We use this way of breaking down arguments into their constituent parts to identify and compare some elements in the structure of multiple-choice options of INVALSI argumentative items.

### Research questions

In our study we focus on written texts, in particular INVALSI multiple-choice items in which students have to choose among different sentences. In this frame, we refine our initial research questions: can we identify common structures in the different answer options in INVALSI tests? How can we carry out *a posteriori* analysis of the argumentative items by using some interpretative tools coming from Toulmin’s model?

### Examples of INVALSI argumentative items

The first example (Figure 1) is a geometry item relating to equivalence between plane figures.

Observe the following figures:

Figure A

Figure B

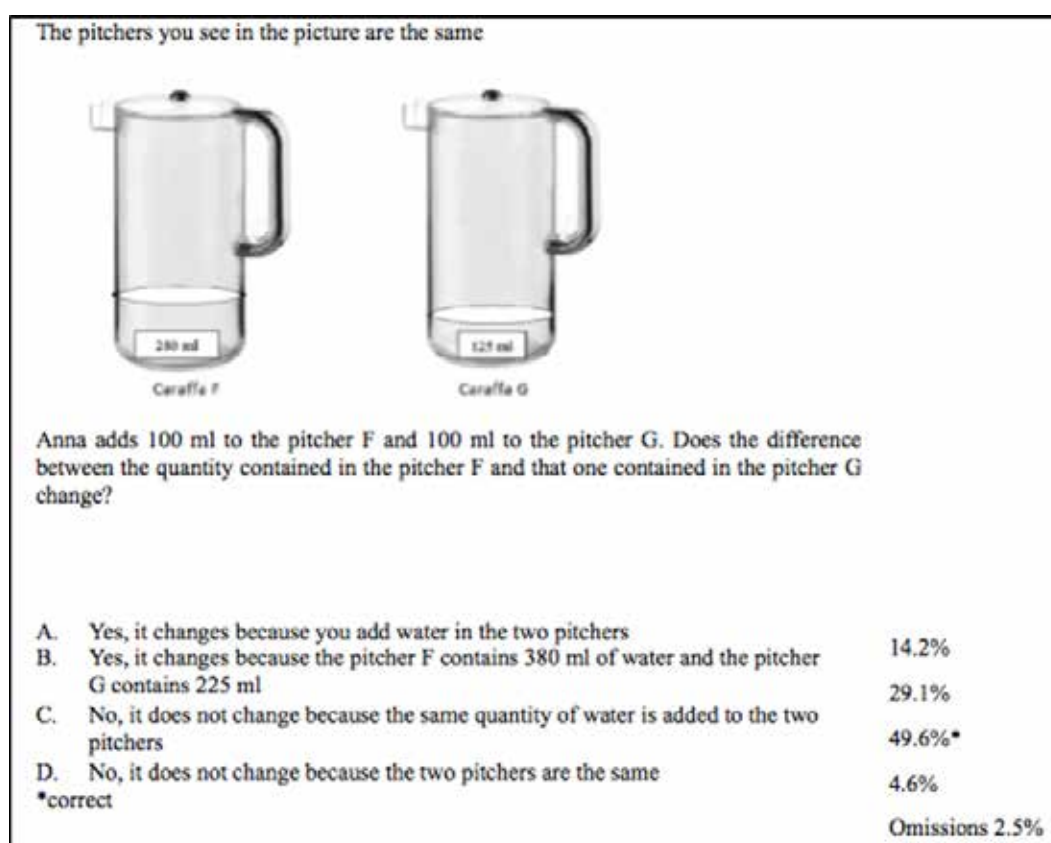

Do the two figures have the same area?

A. No, because the two figures have different dimensions	30.3%
B. Yes, because the triangles that make up the figure A are the same ones that make up the figure B	41.4%*
C. No, because the two figures have different perimeters	19.6%
D. Yes, because each of the two figures is filled with right triangles	7.4%
*correct	Omissions 1.3%

**Figure 1: Item from SNV 2016, grade 5 (indicating the percentage for each option) (translation by the authors)**

The student must choose the correct answer: the options are built up by two “Yes” and two “No” followed by arguments that have to justify correctly the answer. The stem consists of two figures and

a question that is common in activities about geometrical objects in primary school. This example shows a structure in the construction of the item that we identified as very common in the INVALSI argumentative items. In the different options, the student has to choose not only if the answer is Yes or No, but also the correct argumentation: i.e. the argumentation that is relevant and useful to answer correctly the question. For these reasons, all the sentences after Yes and No are true sentences, but in only one is there a correct argument. In particular, options A and C (together are chosen by about the 50% of students) are both referring to the fact that the dimensions of the rectangles are different: these may refer to a misconception like "if the sizes are different then the area must be different" quite common in primary school. Option D (chosen by 7.4% of the students) is weaker and refers to invariance of shapes (right triangles). Using the Toulmin's model to interpret the item structure, we can identify Data (D) (i.e. the representation of two equivalent rectangles made by the same triangles), Claim (C) (i.e. the recognition of the equivalence of the figures: "Yes, they have the same area" or "No, they don't have the same area") and Warrants (W) (i.e. the inference rule which allows Data (D) to be connected to Claim (C) about the identification of the same area of the rectangles). Therefore, focusing on the structure of the four options, the students have to choose the options where they recognize both the right answer to the question about the equivalence of the figures area and the right justification of it. The second example (Figure 2) deals with a situation framed in a field of experience external to mathematics.

**Figure 2: Item from SNV 2016, grade 5 (indicating the percentage for each option) (translation by the authors)**

This item requires to understand that the difference in the amount of water contained in equal pitchers doesn't change if we add the same amount of water in each one of them. The students have to recognize the correct statement that justifies this invariance. The incorrect options highlight misconceptions related to the situation of invariance or difficulties in identifying a condition that is necessary, but not sufficient. In this example, the students can identify arguments (Warrants) linked also to everyday life experience, or can use forms of reasoning for general principles about adding quantities to different initial amounts. The statistical data show that this item has a higher percentage of correct answers: we can conjecture that it is because it refers to everyday life experiences. The option B focuses on the difference between relative and absolute increase and it was chosen by many students (29.1%). In fact, the other options show more general arguments about shape and content of the pitchers.

Using the Toulmin's model: data (D) is represented by the figure and the text of the question that describes the situation. Claim (C) is about the increase of water in the two pitchers after the addition of the same quantity of water. Warrant (W) is given by the arguments in support of responses (two for answer Yes and two for answer No). Although the mathematical content and context are very different from the previous example, we identify the same structure: all the arguments are true, but only one is adequate in order to support the correct answer.

Summarizing, the analysis of the structure of these two items show that all the Warrants are true and pertinent (i.e. relating directly) to the mathematical content of the item, but only one is adequate, that is useful to support the Claim.

## Discussion

In this paper we discussed some features of INVALSI items focused on argumentation: multiple-choice items where the student has to identify the right arguments to support his/her answer concerning a given statement. Analyzing this tests, we demonstrate how certain aspects of argumentation can be assessed through the use of standardized items. In particular, the ability of the students to choose the correct argument to support a statement. We are aware that the analysis of other argumentative skills, such as the production of justifications to support a claim, requires analysis tools other than the Toulmin's model, which provides us with information only on the structural aspects of the argumentation. By means of two examples, we show some characteristics of argumentative items and we use Toulmin's model as *a posteriori* interpretative tool to describe and interpret the structure of these items. We chose Toulmin's model as an interpretative tool because it allows us to analyze retrospectively the structural aspects of argumentative items focusing on the characteristics of the justifications (Warrant), regardless of the mathematical content involved. The analysis carried out in this paper wants to show how, even if we chose two items that deal with different topics and contexts, we can identify in the structure of the items some similar characteristics: i.e. structural characteristics that the use of Toulmin's model can clearly highlight.

In the examples presented here all the justifications (Warrants) are true and pertinent, but in INVALSI tests we can also find items where all the justifications (Warrants) are true but only one is pertinent or items where the incorrect options are false but pertinent. In the latter case, as regards the first example (Figure 1), the three incorrect response options could have been as follows: *No, because the*

*two figures have different areas; No, because the two figures have a different number of triangles; Yes, because the two figures are congruent.* The justifications are false, but directly relevant (i.e. pertinent) to the context of the question.

It is clear that, as underlined at the very beginning of the paper, standardized items can evaluate only some features of argumentation, as well as the Toulmin's model can identify only specific types of argumentation structures, but this doesn't mean that a study about these elements cannot give us some educational information about the assessment on argumentation and helpful tips for designing other kinds of standardized items about argumentation. As a matter of fact, in the further steps of our study, we are investigating if the Toulmin's model can become a useful *a priori* tool in order to construct items in which the argumentations have different structures: i.e. items with the same structure of those presented here; items where it is explicit that the answer is No (or Yes) and the students have to choose the only warrant that justifies it; items in which, starting from the data and by a given warrant, the students have to choose which statement, among those proposed, is justified by the argument (from Warrant to Claim).

Therefore, in our study the Toulmin's model is being transformed from a *a posteriori* analysis tool that sheds light on the passage from Claim to Warrant (I have a Claim and I have to identify which Warrant is adequate to justify that Claim) to a tool for constructing argumentative items, that to say to a *a priori* analysis tool.

## Evaluating students' self-assessment in large classes

University of Helsinki, Finland; <sup>1</sup>jokke.hasa@helsinki.fi, <sup>2</sup>johanna.ramo@helsinki.fi,  
<sup>3</sup>viivi.virtanen@helsinki.fi

*This study is part of an ongoing larger project concerning student self-assessment skills in university courses. We have developed a method enabling large cohorts of students to assess their own learning outcomes and to give their own course grades with the help of an automatic verification system. This paper explores the question of accuracy, namely, whether the self-assessed grades correspond to the students' actual skills, and how well the automatic system can pick up issues in the self-assessment. Based on an expert's evaluation of the skills of two students, we conclude that although for large part the model works as intended, there are some cases where neither the self-assessment nor the computer verification seem to be accurate.*

**Keywords:** Self-assessment, assessment for learning, digital assessment, accuracy, large classes.

### Introduction

The ability to judge the quality of one's own work is one of the core skills that should be developed during university studies. Self-assessment has been viewed as a valuable assessment process through which student can learn to understand the expectations, criteria and standards used in assessment, and further, to be able to regulate own learning and acquire skills for lifelong learning (Falchikov & Boud, 1989; Kearney, Perkins, & Kennedy-Clark, 2016). However, academic community seem to be resistant to change the prevailing assessment practices focusing on testing and grading, and practices such as self-assessment are scarcely implemented at course level (Boud et al., 2018; Postareff, Virtanen, Katajavuori, & Lindblom-Ylänne, 2012).

In this paper, we draw attention to assessment practices in university first-year mathematics by examining an implementation of student self-assessment processes into large class setting. During this process, students frequently evaluated the quality of their learning outcomes, received feedback on their performance, and finally decided their own grades according to particular criteria. The intended learning outcomes were made transparent through a rubric including both content knowledge and generic skills, such as writing mathematics. The digital environment gave opportunity for monitoring learning process and giving real-time formative feedback in line with previous research on online assessment (Ćukušić, Garača, & Jadrić, 2014; Gigandi, Morrow, & Davis, 2011; Ibabe & Jauregizar, 2010), and further, it formed a basis of assessment of the student's progress. The emphasis of self-assessment was in developing student capability in making evaluative judgements (Ajjawi, Tai, Dawson, & Boud, 2018) and building their metacognition skills (Mok, Lung, Cheng, Cheung, & Ng, 2006), so that the students' ability to self-regulate their learning for current and future learning would improve. We fill the gap in research by showing how, in the case of summative self-assessment, the problems aroused by large class setting were resolved by using digital and automatic verification and real-time feedback.

## **Self-assessment as a tool for learning**

Self-assessment can be defined as a process during which student evaluate their own achievements and judge about their own performance (Falchikov & Boud, 1989). The judgements students make are based on information and evidence about their own performance collected from various sources (Yan & Brown, 2017). In this paper, we refer to self-assessment as a process in which the students evaluate their own progress and performance and give justifications for the result of their evaluation according to teacher-given criteria showing intended learning outcomes.

The use of self-assessment has been shown to improve student engagement and motivation (e.g. Andrade & Du, 2007; Mok et. al, 2006), self-efficacy (Kissling & O'Donnell, 2015) and academic performance (Ibabe & Jauregizar, 2010), while the ability to self-assess is reportedly intermingled with ability to self-regulate own learning (Panadero, Brown, & Strijbos, 2016) and with life-long learning skills (Kearney et al., 2016). Consequently, the literature encourages the use of self-assessment for formative purposes. Research shows that in large class settings digital environments with effective formative online assessment can foster a learner-centred focus and engagement in learning (Gigandi et al. 2011; Ibabe & Jauregizar, 2010). Recent results show that online self-assessment can also improve students' academic success (Ćukušić et al. 2014). However, the debate concerning students generating their own grades by self-assessing their own work is more complicated and constantly questioned (Boud et al., 2018; Tejeiro et al., 2010). One of the main challenges regarding self-assessment for grading is the question of accuracy: How can we be sure that students' grades are valid and reliable?

### **The question of accuracy**

Many studies have found high correlations between self- and teacher-ratings (Falchikov & Boud, 1989; Kearney et al., 2016). The results indicate that students are able to make reasonable accurate judgements if they are properly provided with training and background information to the process. Also, students vary in their capability to evaluate their performance e.g., high achievers tend to underestimate their performance whereas low achievers tend to overestimate it (Boud & Falchikov, 1989; Boud et al., 2013; Kearney et al., 2016). However, the accuracy of student self-assessments can be improved through using criteria and standards (Andrade & Du, 2007), while students need to have multiple opportunities for practising self-assessment in relation to given criteria, with feedback to help calibrate the judgements (Hosein and Harle, 2018; Kearney et al., 2016). On the other hand, Boud, Lawson and Thompson (2013) argue that increase in accurate self-assessment is not immediately transferable, because standards and criteria are somewhat domain-specific. Hence, we suggest that in order to understand the expectations, criteria, and disciplinary standards of mathematics, and to develop capabilities to make accurate and realistic assessments on own learning processes and outcomes, it is required that self-assessment processes are implemented in first-year university mathematics. However, in large class setting, typical to that learning context, the challenge how to give evidence-based feedback for improving the accuracy needs to be resolved.

### **The DISA model**

This study is part of a research project centred around an assessment model called DISA (**D**igital **S**elf-assessment). In the model, students assess their own learning outcomes throughout the course

by using a detailed rubric articulating the subgoals of the ultimate intended learning outcomes. Learning goals and criteria are clearly identified, and through self-assessment activities the students are actively engaged with them. Evidence of learning is elicited during the course, and students receive feedback for their self-assessment from an automatic digital system.

The feedback is generated in the following way. Every course task has been linked with the learning objectives it is supporting. This enables the automatic system to compute, based on the student's coursework, an index from 0 to 1 for each learning objective. This index estimates how well the student has acquired the learning objective. From these indices, the system then computes tentative grades in each course topic. These tentative grades are compared to the student's self-assessed grades, and the student is advised either to consider a higher or a lower grade for themselves.

In addition, self-assessment is used for summative purpose in the end of the course, as the students self-assess and justify how well they have achieved the intended learning outcomes, and proceed in deciding their own course grade based on the self-assessment. In order to prevent abuse of the self-assessment process, the system described above is used to verify the validity of the course grades. If the self-assessed topic grades differ too much from the computed ones, the student's final course grade is disputed. Earlier results imply that the model supports students in using deep learning approach, and encourages them to study for themselves, not for an exam (Nieminen, Rämö, Häsä, & Tuohilampi, 2017).

### **Aim of the study**

This study aims at gaining a better understanding of the use of self-assessment as an integral part of assessment in a large first-year university mathematics course. In the course context, self-assessment is used to give students an opportunity to think metacognitively about their learning. We hypothesise that student active engagement into self-assessment processes is enhanced if these processes are valued in grading, but then, the question of accuracy needs to be resolved. This question is two-fold: firstly, we are interested in the validity of the student grades, in other words, whether they reflect true learning, both in content knowledge and domain-specific generic skills such as writing mathematics. Secondly, we need to examine the reliability of the automatic verification system: can it spot the cases where self-assessment is inaccurate? The research questions in this study are:

1. How do the students' evaluations of their own skills compare with evaluations performed by the automatic verification system?
2. How does an expert judge the student's acquired skills in cases where the automatic verification disagrees with student's self-assessment?

### **Method**

This study uses data collected from students taking a first year mathematics course at a major research-intensive university in Finland. The second author was the lecturer for the course. The course was a proof-based linear algebra course dealing with finite-dimensional vector spaces, and it lasted for seven weeks (half a term). During the course, students were given weekly problems to solve, part of which were assessed and given feedback on. Some of the tasks were assessed by the tutors, some by an automatic assessment system called Stack (Sangwin, 2013). Some tasks were also peer-reviewed.

The course was not graded with a final exam, but grading was done by self-assessment using the DISA model. The self-assessment was based on a detailed learning objectives matrix prepared by the teacher. The learning objectives were divided into 10 topics: six content-specific and four generic skills topics, and the students were asked to give themselves a grade from 0–5 in each of these topics, 0 meaning fail. They were also asked to write down reasons for choosing that grade. In the end of the course, students chose their own final grade. They were left to decide by themselves how to combine the grades from the different topics. The DISA system was used to verify the final self-assessment.

It is worth noting that, in the Finnish context, although the teacher is responsible for the course grades, these can be awarded by any means the teacher chooses. There is little fear of distorting the grades, as the final grade of a first-year mathematics course carries very little weight in the final outcome of a student's study programme. Also, all courses and exams can be usually retaken as many times as the student wishes.

The participants of this study were 158 students who took the linear algebra course described above, gave themselves their own grades using the DISA model, and gave consent for using their data. Most of the students were majoring in either mathematics, mathematics education or some other field related to mathematics such as computer science, physics or chemistry. Most students were first year students, but the cohort included also older participants, up to post-doctoral level.

We narrow our study to two of the ten learning objective topics of the course: (1) “Matrices” (content-specific) and (2) “Reading and writing mathematics” (generic skill). These two topics were chosen since both are among the most central topics of the course and there were relatively many tasks linked to them. Also, we wanted to compare self-assessments on a content-specific topic with those on a generic skill. Henceforth, these topics are abbreviated as [M] and [RW]. Examples of learning objectives pertaining to these topics are given in Table 1.

Topic	Skills corresponding to grades 1-2	Skills corresponding to grades 3-4	Skills corresponding to grade 5
Matrices [M]	I can perform basic matrix operations and know what zero and identity matrices are	I can check, using the definition of an inverse, whether two given matrices are each other's inverses	I can apply matrix multiplication and properties of matrices in modelling practical problems
Reading and writing [RW]	I use course's notation in my answers	I write complete, intelligible sentences that are readable to others	I can write proofs for claims that concern abstract or general objects

**Table 1: Part of the learning objectives matrix of the course. In total, there were 10 topics and 10–15 learning objectives in each topic**

To answer Research question 1, we compared the grades students gave themselves on the two topics in the final self-assessment with the results of the automatic verification of that self-assessment. The computations were done with R version 3.5.0. For Research question 2, coursework and final self-

assessment of two students whose self-assessment was poorly in line with the automatic verification were chosen for closer inspection. In this manuscript, we call them Student A and Student B. The two students' anonymised answers to all of the written tasks as well as their Stack exercise points were analysed by the second author. This author was also the teacher of the course and can be regarded as an expert in the subject. When the expert was grading the students, she did not know how the students had assessed themselves. The expert read every written solution the student had submitted, and evaluated which learning objects in topics [M] and [RW] the student had reached.

Every time the expert could see the student mastering a learning object, she made a note in the learning objectives matrix. After that, there were learning objectives for mastering of which the student had not provided any evidence in the written solutions. The expert then looked at the Stack exercises that were linked to these learning objectives to see how many points the student had received from them. She used the information in determining whether the student had reached the remaining learning objectives. When the expert had considered each learning objective, she awarded the student a grade in both topics by looking from the learning objectives matrix which grade the reached learning objectives corresponded to. In borderline cases, the expert used her expertise as a mathematician and teacher of the course. For the topic "Reading and writing mathematics", the expert could only evaluate the student's skills in writing as there were no tasks that were linked to reading skills.

## Results

### Research question 1: comparison of self-assessed grades with automatic verification

The distributions of the self-assessed grades in the two topics [M] (Matrices) and [RW] (Reading and writing mathematics) are shown in Table 2. We see that the students gave the grades 3 and 4 more often for [RW] than for [M], but the top grade 5 was more common in [M] than in [RW].

Grade	1	2	3	4	5
[M]	3	10	25	47	73
[RW]	2	10	37	58	51

**Table 2: Frequencies of each grade in the two topics**

The computer verification system computed tentative grades for the two topics for each student. The distribution of differences between the computed grade and student self-assessed grade are reported in Table 3.

Difference	-5	-4	-3	-2	-1	0	1	2
[M]	1	1	5	20	26	86	19	0
[RW]	0	2	6	15	20	75	34	6

**Table 3: Frequencies of the differences: computed grade minus self-assessed grade in the two topics**

We see that the computer and student grades agree well. In [M], there are 86 matches, 53 cases in which the self-assessed grade was higher than the computed grade (negative difference), and only 19 cases in which the self-assessed grade was lower (positive difference). In [RW], there are 75 matches,

43 cases in which the self-assessed grade was higher, and 40 cases in which the self-assessed grade was lower. In both topics, between 81-83 % of self-assessed grades lie within 1 grade point from the computed grade.

### **Research question 2: Expert opinion in conflicted cases**

Student A's self-assessed grades were lower than the computed ones. For both topics, the self-assessed grade was 4 and computed grade 5. The expert's evaluation agreed with the computed grades. The expert observed that Student A had done almost all tasks during the course. Even though not all the answers were correct, all the learning objectives in topic [M] were fulfilled. Students were asked to make corrections to some tasks, and student A had always resubmitted solutions written in good mathematical style. The student's explanations were concise and readable, and the student was able to construct proofs concerning abstract mathematical objects. Based on this, the expert's grade for topic [RW] was 5.

Student B's self-assessed grades were greater than the computed ones. For topic [M], the self-assessed grade was 5 and the computed grade 3. The expert's evaluation yielded grade 4, that is, something in between. For [RW], the self-assessed grade was 3 and the computed grade 1. The expert's evaluation agreed with the self-assessed one. The expert observed that Student B had submitted only a fraction of the course tasks. However, the expert was able to evaluate from the solutions that Student B accomplished almost all learning objectives in [M]. Some of Student B's skills were shown in the intermediate steps of tasks that were not directly linked to topic [M]. For example, the student determined whether given vectors are linearly independent by forming a system of linear equations and calculating the determinant of the coefficient matrix. This showed that the student knew how invertibility of matrices is connected to the number of solutions of a system of linear equations even though the topic of the task was linear independence. Student B had not corrected any solutions when encouraged to. According to the expert, the student reached partially all the learning objectives in [RW], but did not fully master any of them, not even the ones corresponding to grade 1. For example, the student mixed up equivalence arrows with equality signs, wrote long, confused sentences and used "if-then" structures inside a proof in the place of assumptions and conclusions. However, the overall structures of the proofs were correct. Based on this, the expert's interpretation was that the student's grade for [RW] was 3.

### **Discussion**

In this study, a new model of determining course grades via self-assessment was examined with a focus on the accuracy of the self-assessed grades. The students gave themselves grades in all course topics, and these grades were automatically verified by comparing them against the course work the students had done. We analysed the results of the verified self-assessment in two topics, one content-specific topic (matrices) and one subject-related generic skill (reading and writing mathematics).

The students' self-assessment agreed well with the automatic verification. Most discrepancies are within one grade point, which can be explained by the coarseness of the grading scale: the "real" skill level is often between two grade points and must be forced to one or the other direction. The high agreement is not surprising, as previous studies have shown that explicit criteria and standards support self-assessment, as does frequent practice and feedback (Andrade & Du, 2007; Kearney et al., 2016).

It remains to be studied how great an effect the feedback that the students received for their self-assessment exercises had on their final self-assessment.

The students gave fairly good grades to themselves in both examined topics. For reading and writing mathematics, the grades were more concentrated around the second-best grade, whereas for matrices, the top grade was clearly the most common grade. Perhaps it was easier for the students to understand the learning objectives as well as recognise their achievements in the mathematical topic, and without clear evidence for mastery, they were hesitant to award themselves the best grade in a generic skill. Our results could be understood in the view of previous results (Falchikov & Boud, 1989) showing that in science courses, self-assessment was more accurate than in other fields.

We examined more closely two students whose self-examined and computed grades differed. In the first case, self-evaluated grades were below the computed ones. The expert's evaluation agreed with the computed grade. The student was a high achiever, and from previous studies we know that such students tend to underestimate their performance (Boud et al., 2013; Kearney et al., 2016). In the second case, the self-evaluated grades were above the computed ones. The expert's evaluation was between the two for the mathematical topic and agreed with the self-assessed grade for the generic skill. In this case, the student had skipped many tasks which made it difficult for the automatic system to estimate the grade fairly. Also, the expert noted that the student seemed to have some skills from all grade categories in the learning objectives matrix, but not to have fully reached any. This kind of case would be very difficult for the automatic verification system to estimate correctly.

The study used a method in which an expert evaluated students' skills based on all the work they had done on the course, evaluating against the intended learning outcomes, not by grading individual tasks. The method suffered from some of the maladies related to teacher evaluation, such as time restriction and personal bias. The accuracy of teacher-grading is not an issue to be taken as obvious truth (Brown, 1997). One should also note that neither the expert nor the automatic system were able to evaluate students' reading skills even though they were included in the self-assessed grades.

This study opened a new way to critically examine a self-assessment model as a viable option for grading students. We did not find any fundamental problem with reliability. However, at least in one of the studied cases, the verification system did not estimate the student's skills very well. A larger sample needs to be studied in order to find out whether such issues are common. Also, we need to study students' written justifications for their grades in order to better understand what is involved when the self-assessment process does not go as intended.

*In this paper, we present a questionnaire that we have designed to establish a picture of secondary school teaching assessment practices in mathematics. This research follows a request from the Ministry of National Education, to take into account a specific mathematical content (algebra) in the analysis of teachers' practices at a large scale (1200 teachers). We begin by presenting our theoretical and methodological tools to characterize teacher assessment practices, and then present the project and the methodology adopted to link teachers' practices and their students' learning. We then give some examples of questions that we have designed for the teachers' survey, to be implemented in the fall of 2018.*

*Keywords: Assessment, teachers' practices, algebra, national surveys, teacher survey.*

### General presentation of the project

The DEPP (Directorate for Evaluation, Prospective and Performance) is responsible for the design, management and operation of the statistical information about the education system in France. It contributes to the evaluation of policies conducted by the Ministry of National Education. It has already developed an expertise about assessment, through national and international surveys on education, which focuses mainly on generic teaching conditions and practices, and not on practices related to a specific content. At the same time, the DEPP periodically assesses 5th graders (last year of elementary school) and 9th graders (last year of middle school) in the curriculum's disciplines by the CEDRE test (Cycle of Disciplinary Evaluations carried out on a Sample basis).

The new cycle of student's assessment which began in June 2018 is the first opportunity to establish a picture of teaching practices on a specific mathematical content. In this context, the goals of the PRAESCO 2017-2019 programme (Enquiry on Teaching Practices based on Specific Contents) are to make available to policy-makers and the educational community a set of indicators on teaching practices in mathematics, and to research the effects of these practises on the students' learning of specific mathematical contents (numbers and calculation for the 5th graders and algebra for the 9th graders). The role of the researchers commissioned by the DEPP is to build a questionnaire based upon a theoretical framework for identifying variables in mathematics teaching modalities, and to bring a scientific and didactic dimension to the analysis of this survey. In this paper, we focus on the design of the survey about teachers' assessment practices at the 9<sup>th</sup> grade level. Our theoretical and methodological frameworks

We explain our theoretical framework for the analysis of teachers' practices and more particularly for assessment practices in relation to students' learning in mathematics. We also explain our choice to select algebra as the specific mathematical content for the survey.

## Teachers' practices and students' learning in mathematics

Our hypotheses on teaching and learning are based on the adaptation of the Activity Theory for didactic (Vandebrouck, 2018): it is mainly through students' mathematical activities that their learning takes place, activities caused, in large part, by the tasks they are given to do. The tasks therefore have a central place in our analyses, to anticipate possible learning for the students, but also to characterize teachers' practices through their choice of tasks for the students and the actual implementation of the work around those tasks in class.

To have a more comprehensive view of teachers' practice, we adopt the theoretical framework of the Double Approach (Robert & Rogalski, 2005), taking also into account some determinants of teacher practices that are not only related to the targeted students' learning. We consider the various constraints that influence the teaching profession, which leads us to include in our analysis of teachers' practises, institutional, social and personal components of the teaching profession, in addition to cognitive and mediative ones.

In this large panorama of teachers' professional activities and context, we consider that assessing students plays a significant role in the teaching and learning process, as it allows the students' actual mathematical activities to be taken into consideration by the teacher, to build appropriate teaching, in the short or long term. This is why our questionnaire includes a section about assessment practices, that we will describe below.

### Assessment

In our previous work (Horoks et al., accepted; Pilet & Horoks, 2017), we have built a framework for analysing the assessment practices of secondary school teachers in mathematics, considering the specificities of the mathematical content. The various definitions of *assessment*, found in the literature and on which we rely, highlight three dimensions in the act of evaluation: taking information, interpreting it and using it for decision-making. We characterise *assessment practices*, using De Ketele's (2010) definition, through everything the teacher does to take information about students' mathematical activities (what they do, know, say, write) and how the teachers use this information, especially to promote students' learning. For De Ketele (*ibid.*), this information must be sufficiently relevant, valid and reliable, leading the teacher to examine its degree of adequacy with a set of criteria, linked to the teacher's goals, to make a decision. For Black & Wiliam (1998) also:

The term 'assessment' refers to all those activities undertaken by teachers, and by their students in assessing themselves, which provide information to be used as feedback to modify the teaching and learning activities in which they are engaged. (Black & Wiliam, 1998, pp.7-8)

Depending on the function given to assessment by the teacher, this collection and exploitation of information can be done in different ways, more or less formal and with greater or lesser effects on teachers' subsequent choices for their class.

For Black & Wiliam (1998), students' assessment is called *formative* when the information collected by the teacher is used to meet students' needs and when the students can self-evaluate through the realization of the tasks that they have been given. Ash & Levitt (2003) argue that formative assessment is a joint teacher-student activity, which remains fairly close to what the student already

knows how to do. The teacher collects clues about one student's activity in order to analyse this activity and plan the next step to help this student evolve.

## Algebra

In this project, our approach to analyse teachers' practice, focuses on the mathematical contents to be taught, which led us to choose the field of elementary algebra, by consensus among the participants of the project, and for several reasons. First of all, because elementary algebra represents an important challenge for the future of students' studies in secondary and higher education, but also because teachers often express difficulties in teaching algebra (Kieran, 2007). It is also a choice that allows us to build on existing research results in mathematics education about the teaching of algebra. We have relied on the work of (Grugeron et al., 2012; Pilet, 2015; Sirejacob, 2017) who, on the basis of an epistemological study, have established a reference for a *mathematical organization* (Chevallard, 1999) of the teaching of algebra at this school level. The latter provides the types of tasks representative of the algebraic domain, which makes it possible to question the coverage of this domain by the tasks proposed by teachers, and the pertinence of these tasks (for learning or for assessment). This reference also provides information on the levels of reasoning expected from the students, and on the properties that can be brought forward by the teacher to institutionalize knowledge, validate or invalidate students' productions.

## Presentation of the methodology

### General protocol

Our framework to analyse assessment practices has already been used for studies involving fewer teachers, but over a longer period (several years). The transition to a larger scale requires a specific methodology, that we have been designing with the DEPP during the first year of the project. The general protocol is presented in Table 1. This study is based on statistical and didactical analyses performed by the researchers.

Period of time	Protocol
January – September 2018	Design of the questionnaire
September - November 2018	Selection of teachers for the first version of the questionnaire
December 2018	Experiment (teacher's first version of the questionnaire and assessment of the students' algebraic skills)
January-February 2019	Analysis of the experimental data and classroom observation for a sample of 50 teachers, improvement of the questionnaire
April – May 2019	Selection of teachers for the final version of the questionnaire, with a sample of 1200 secondary mathematics teachers
June 2019	Implementation of the final version of the questionnaire
June 2019 – February 2020	Analysis of the data

**Table 1: General protocol**

In an attempt to overcome the fact that a questionnaire can only give access to declarative practices, we chose to complete the analyses by observing some teachers in their classes. For that purpose, the first experiment, to be carried out from December 2018, involves only 50 teachers, chosen as a representative sample of teachers in France among the 1200 teachers (in terms of experience, teaching environment and geographical context) selected for the first version of the questionnaire. These teachers will also fill the questionnaire while their students are assessed through a mathematical test.

Later on, they will be observed while teaching algebra in their classroom (on the cognitive and mediative components of their practises, as defined by the Double Approach (Robert & Rogalski, 2005) and also asked questions about their work outside of class. This first step is smaller by the number of teachers involved, but more demanding for the researchers, because of the observation accompanying the questionnaire. It should help us identify whether the questions of the questionnaire are reliable and relevant for characterising teachers' actual practices through their answer to the questionnaire and improve the final version of the questionnaire that will be proposed at a larger scale in June 2019.

In the same perspective, we ask the teachers, in the beginning of the questionnaire, to choose one of their 9th grade classes, and to answer the questions with this particular class in mind. We believe that the identification of a reference class and the choice of a precise mathematical content allow us to get as close as possible to the real practices of the teacher. In addition, an assessment of the students in the teachers' reference class is conducted (around 30 000 students in total), in order to investigate a crucial issue: the impact of practices, and more specifically teacher assessment practices, on their students' learning.

### **Designing the questionnaire**

To design the questionnaire, we brought together a team of researchers in mathematics education and experienced mathematics teachers in secondary education. Regular meetings, some of which were held with the members of the DEPP involved in the project, allowed us to agree on the formulations for the questions, in order to be able to perform a valid analysis of the teachers' answers, both from a statistical and didactical point of view. The questionnaire was then tested on teachers, whom we contacted individually, to ensure that the questions were understood and to have a better idea of the time required to complete the questionnaire, which final online version should not exceed 45 minutes for the teachers to answer.

The questionnaire consists of 121 questions (530 sub-questions in total). For statistical analysis purposes, the questions are closed-questions with multiple choices, with 4 level - scales (of frequency, difficulty, opinion, or adequacy to content or to students). Some of the questions focus specifically on algebraic contents, others focus more broadly on practices when teaching mathematics in general. To support possible results, we sometimes question the same aspect of practices in several questions but with different formulations throughout the questionnaire.

The questionnaire consists of 4 sections, with questions about:

- the teaching context and the teacher's background (experience, training, institutional constraints and possibilities, uses of technology for teaching and personal views on teaching and learning, especially about algebra)
- classroom preparation (resources, selection of algebraic tasks, time allotted to specific contents and tasks)
- management of classroom teaching (classroom work arrangements in the different phases of a mathematics session, interactions in class)
- and student's assessment (20 questions, 106 sub-questions, including 31 sub-questions about algebra).

In this presentation of the 9th grade level survey, we are focusing on teaching practices in elementary algebra, and in particular the practices of the teachers to assess their students' learning on this content. We make the hypothesis that assessment can play a rather important part in students' learning, but of course it is not easy to separate these particular practices, and their effects on students, from the rest of teachers' actions.

### Questions about the assessment practices

In the last section of the questionnaire, we ask questions about teacher's relationship with assessment as well as the way he or she implements assessment in class. Concerning the teachers' relationship to assessment, we want to characterize in particular the functions given to assessment by teachers, including or not a better learning for their students (grade, rank, distribute, sanction, etc. Merle, 2015). In terms of teachers' assessment practices, we have applied the definition of assessment - *taking information, interpreting it and using it for decision-making* - to design this part of the questionnaire.

We want to identify the moments (Chevallard, 1999), where teachers gather information on their students' knowledge (before beginning to teach algebra in their reference class, or at the end of this chapter, and throughout the teaching of this subject), and the means used to do so, through formal or informal processes (Allal & Mottier-Lopez, 2007) and through which type of algebraic task), made more or less obvious for the students by the teachers' discourse.

We also try to appreciate the way teachers interpret some information about their students' possible answers to given tasks, by asking them to comment on student's productions (cf. Figure 1, with a question concerning also the decision making based on this interpretation). It might also give us access to the teachers' relationship to algebra, and the role of error in their vision of mathematics teaching, as well as their consideration of the students' procedures rather than their only results.

Here is the text of a summative assessment task and Guillaume's production:

Here is a calculation program:  
 Choose a number, Add 7, Multiply the result by 4, Subtract 3 to the last result  
 What is the result of this program if at the beginning the chosen number is 6?  
*Guillaume's answer:*  $6+7=13 \times 4=52-3=49$

When I assess Guillaume's production, I consider that:

	I disagree	I rather disagree	I rather agree	I agree
The result is correct, and I won't give Guillaume any feedback on the calculation, as he will understand later why it is not correct				
The answer is correct, but I will write a comment to explain that it is not correctly written mathematically				
If a lot of students have written the calculation this way, I will take a moment to clarify it with the entire class				
The result is false, because the way it is written is not correct				

**Figure 1 – Example of a question about the judgment on a student's production in a summative test**

We also question the teachers about the exploitation they usually do, of the information about their students' knowledge or know-how: if and how they adapt their teaching consequently, for some students or the entire class, and with which support on the mathematical contents.

In fact, several questions about assessment practices appear in other sections of the questionnaire. In the first part, about the context and personal information, we ask teachers if they feel the need for further training about students' assessment, among other topics. We also ask them about the possible origins for their students' difficulties in mathematics, and their students' needs to understand what is at stake in algebra, which can be linked to diagnostic assessment. The choice of tasks that they make for their *reference class*, largely questioned in the third part of the questionnaire, focusing on teachers' preparation of the class, can also be compared with the tasks chosen for assessment, to spot possible gaps between the two.

In the questionnaire's part about the management of the teaching in the classroom there are questions about the collective work on students' productions on a given task, that we link to assessment. Some questions in this part also (see Figure 2) focus on students' error management and ask the teachers to position themselves on the levels of mathematical discourse they generally use with their students (from almost never to very often). The following proposals (figure 2) participate, more or less, to a process of *formative assessment*. For example, Proposal 4 (figure) doesn't rely on the mathematical properties linked to the preservation of equality, but is referring to the gestures accompanying the technique, which we do not believe to be rich enough to help the students understand their mistakes and learn from them (Sirejacob, 2017).

<p>In my class, when solving the equation <math>8x+5 = 3x+20</math>, a student writes:  <math>8x-3x=20-5</math>    so <math>5x=15</math>    so <math>x=10</math></p> <p>Here are different proposals for the teacher to address the error made by this student. Give your opinion on each of these proposals:</p> <ol style="list-style-type: none"> <li>1) <i>The teacher asks the student to recognise the operation between 5 and x, and draws the student's attention on the difference between addition and multiplication.</i></li> <li>2) <i>The teacher asks the student to replace x by 10 to see if 10 is a solution of the equation.</i></li> <li>3) <i>The teacher asks the student to look up in his or her textbook to find the mathematical property to be used here</i></li> <li>4) <i>The teacher asks the student to tell how the 5 can be passed on to the other side of the equation</i></li> </ol>
-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Figure 2 – Example of a question about the management of a student's error in class**

About the particular case of summative assessment, which is the kind of assessment that is the one most associated to the act of evaluation by teachers in France (De Ketele, 2010), the questionnaire asks about its frequency, duration and formats, with a particular interest for the teachers' choice of tasks for that purpose. This choice reveals a potential link with the algebraic tasks chosen for this chapter in the *reference class*, in terms of domain coverage, pertinence for assessment or learning, and also, in terms of complexity and variety among all the possible tasks. The practices for correcting these summative assessments are also investigated (through the scoring, the feedback to students) as they allow us to better understand the function of these assessments and their potential formative dimension (see Figure 3).

After a summative test is taken in my class:

	Almost never	Sometimes	Often	Very often
I give the correction in class for every task in the test				
I give the correction in class only for some of the tasks				
I organise a moment for questions after the students have consulted their corrected paper				
I select some of the students' answers to be discussed collectively in class only for some of the tasks				
I return the students' corrected papers without spending any additional time on it				
I provide a version with the correct answers to the test				

**Figure 3 - Example of a question about the feedback to the students after a summative test**

### Analysing the questionnaire

In order to analyse the teachers' answers to the questionnaire, computed by the DEPP after the implementation of the large-scale survey, and to link them to their students' results to the test in algebra, we rely on hypotheses about the possible impact of assessment practices on students' learning. We suppose that some choices might better promote learning: for example, organising a regular feedback for the students, as part of a formal or informal assessment, comparing different possible students' answers and highlighting the algebraic properties at work behind each procedure, to explicit and validate or invalidate the students' work. From these hypotheses, that will be challenged by the confrontation of the teachers' practices to their students' results, we define several teachers' profiles, including assessment practices in algebra, but also more widely, practices for the teaching of mathematics, in a given context.

This paper is focused today mainly on the design of this survey, as it displays a very ambitious methodology, and because we do not have results to show about this study at the moment. But we should be able to present already some preliminary findings at the time of the conference, about the next steps of the survey.

### Conclusion

This project presents major challenges, since it is the first requested by the DEPP in France to focus on the diversity of teaching practices relating to specific disciplinary content, at a large scale. The survey is not a protocol for assessing a teacher's individual performance but aims to appreciate the diversity of teaching practices. The simultaneous test addressed to the students along with the teachers' questionnaire, might also allow us to link teaching practices and students' learning at a large scale.

# Preservice Middle School Mathematics Teachers' Development in Formative Assessment

Gözde Kaplan Can<sup>1</sup> and Çiğdem Haser<sup>2</sup>

<sup>1</sup>Middle East Technical University, Ankara, Turkey; gkaplan@metu.edu.tr

<sup>2</sup>University of Turku, Finland; cigdem.haser@utu.fi

*The study was conducted to investigate preservice middle school mathematics teachers' professional development in formative assessment practices they plan to implement in classrooms. Basic qualitative research method was employed in this study. Incomplete and Improper Lesson Plan Task developed by the researchers was implemented to 47 2<sup>nd</sup> year, 37 3<sup>rd</sup> year, and 27 4<sup>th</sup> year preservice middle school mathematics teachers. Findings of the study indicated that participants who took measurement and assessment course and methods of teaching courses (3<sup>rd</sup> year and 4<sup>th</sup> year preservice teachers) emphasized integrating formative assessment strategies more than 2<sup>nd</sup> year preservice teachers. None of the participants mentioned to give opportunity to students to assess themselves or provide feedback to the students in order to enhance their learning. 3<sup>rd</sup> year and 4<sup>th</sup> year preservice teachers were also more successful in detecting the improperness of the lesson plan.*

*Keywords: Preservice mathematics teachers, formative assessment, professional development.*

## Introduction

Formative assessment is used to collect evidence about students' current level of understanding a concept and their learning progress. Hence, it does not serve for certifying students' competence (Black & Wiliam, 1998). Formative assessment provides information to both students and teachers about their performance and instruction (Sadler, 1989). Any assessment is formative if this information is used as an evidence to make necessary changes in the teaching ways and strategies to meet students' learning needs and to promote their learning (Black & Wiliam, 1998; Wiliam, 2007). Wiliam and Thompson (2008) suggested a formative assessment framework shown in Table 1 considering peer-teacher-learner interactions and three instructional processes; *where the learners are in their learning, where they are going and what needs to be done to get them there* as underlined in Ramaprasad's (1983) definition of feedback.

	Where the Learner is Going	Where the Learner is Right Now	How to Get There
Teacher	Clarifying and sharing learning intentions and criteria for success	Engineering effective classroom discussions and tasks that elicit evidence of learning	Providing feedback that moves learners forward
Peer	Understanding and sharing learning intentions and criteria for success	Activating students as instructional resources for one another	
Learner	Understanding learning intentions and criteria for success	Activating students as the owners of their own learning	

**Table 1: Framework relating strategies of formative assessment to instructional processes (Wiliam & Thompson, 2008, p.63)**

The framework consists of five key strategies and it has one *big idea* that evidences of students' processes can be used to make adjustments in instruction in line with students' needs (Wiliam, 2007). According to the five key strategies: Teachers need to clarify and share learning intention and success criteria with the learners in order to provide them with an understandable picture of the learning targets (Wiliam, 2007). In this way, learners can comprehend the meaning of the lesson objectives and be aware of what they are supposed to do in order to achieve learning targets. Sharing success criteria or rubric with the learners is also crucial with regard to formative assessment because whether the learners grasp the success criteria need to be ensured before expecting good performance from them (Moss & Brookhart, 2009). Additionally, teachers need to reveal learners' current level of knowledge so that they can adjust their instruction according to students' needs and plan further instructional steps (Black, Harrison, Lee, Marshall, & Wiliam, 2003). Teachers can elicit students' learning by engineering effective classroom discussion through asking qualified questions and observing students' learning progress (Schachte, 2009).

Feedback has a crucial role in formative assessment especially when it is used to improve learners' performance (Wiliam, 2007). Providing feedback to the students can increase their participation to the tasks and facilitate their learning (Black & Wiliam, 1998). Being responsible for their own learning improves students' ability to judge themselves and effectiveness and quality of learning (Panadero, Jonsson, & Botella, 2017). Learners' communications and interactions in the classroom activities and lesson content are also essential for formative assessment (Moss & Brookhart, 2009) because they improve learners' motivation, make them cooperative workers (Sadler & Good, 2006) and increase their achievement.

Achieving quality in evidences collected about students' current level of understanding depends on carefully planned formative assessment practices. Based on Tyler's (1950) linear-relational model of instructional planning, teachers are supposed to decide how to evaluate students' learning and how they will make inferences from learning outcomes before instruction begins (as cited in Campbell & Evans, 2000). Hence, lesson planning is a significant process in the implementation of qualified formative assessment practices.

Knowing how to plan and implement formative assessment is crucial for teachers and for preservice teachers. Hence, teacher education programs need to train preservice teachers to increase their awareness of the significance of formative assessment and capabilities of planning and implementing formative assessment in their classrooms efficiently. Therefore, how teacher education programs train preservice teachers on formative assessment needs to be investigated.

The current study aimed to investigate preservice middle school mathematics teachers' (PST) professional development in formative assessment they plan to implement in classrooms. More specifically, the research question guided to the study was "How does PSTs' formative assessment practices change as they progress in middle grades mathematics teacher education program?" This question was sought by exploring PSTs' performance on a task where they were expected to realize the lack of formative assessment practices and suggest practices to improve the task. The nature of the mathematical tasks was not the focus of the study.

## Methodology

Basic qualitative research method (Merriam, 2009) was employed in this study in order to reveal PSTs' professional development in formative assessment they plan to implement in classrooms. The formative assessment framework given in Table 1 guided the researchers in the preparation of the data collection instrument and analysis of the participants' responses.

### Participants and Context of the Study

Participants of the study were 111 PSTs (47 2<sup>nd</sup> year, 37 3<sup>rd</sup> year, and 27 4<sup>th</sup> year PSTs) enrolled in four-year middle grades (grades 5-8) mathematics teacher education program at a public university in Turkey. The program offers mathematics and introductory education courses in first two years. Instructional principles and methods course is offered in the fall; measurement and assessment course is offered in the spring semester of the second year. PSTs take mathematics teaching courses in the third year while school experience and practice teaching courses are offered to them in the fourth year of the program.

Instructional principles and method course focuses on how to write observable and measurable objectives and prepare a lesson plan which includes beginning, middle, end, and assessment sections. Measurement and assessment course focuses on different assessment types including formative assessment and the development process of assessment instruments with rubrics based on objectives. In methods of teaching courses, PSTs are introduced basic principles of mathematics teaching, teaching methods and materials. Every week, they are expected to prepare a lesson plan including assessment part related to that week's topic and discuss these plans in terms of classroom activity and lesson flow. There is not specific emphasis on how PSTs plan to carry out assessment part of the plan in this course. Within the context of school experience course, PSTs are expected to observe their mentor teachers' instruction. They are required to prepare lesson plans for their teaching practice for at least two class hours in practice teaching course and to implement at least one of these plans in the practice school. Data of the study were collected in the fall semester which means that 2<sup>nd</sup> year PSTs have not completed measurement and assessment course yet, 3<sup>rd</sup> year PSTs have only been offered one mathematics teaching course and 4<sup>th</sup> year PSTs have not taken practice teaching course yet.

### Instruments and Data Collection

Data were collected through a task which consists of an incomplete and improper lesson plan and a case where PSTs pretended being in-service mathematics teachers implementing this lesson plan. Lesson plan aimed to cover three 6<sup>th</sup> grade objectives related to equivalent fractions and included a group work activity sheet. Fractions concept was chosen since it forms a basis for other content areas (Siegler et al., 2012) and PSTs had fractions tasks in all mathematics education courses. The plan was incomplete because any wording that imply formative assessment strategy as stated in Table 1 was excluded from the lesson plan. It was improper since one of the three lesson objectives was immeasurable and unobservable, there was not any activity or question related to one other objective, there were inconsistencies between objectives and questions in the assessment part, and there was no rubric for the questions in the assessment part. Moreover, the structure of the questions in the assessment part was weak since they were true-false questions which were limits gathering feedback about students' learning. Task also included four questions guiding PSTs to suggest formative

assessment strategies to strengthen the lesson plan. Expert opinions of three in-service mathematics teachers who graduated from the same teacher education program, three teaching assistants who often gave feedback to PSTs' lesson plans and one mathematics education researcher were obtained in order to ensure the content related-evidence of validity. They were asked to comment on if the questions were qualified to elicit PSTs' formative assessment strategies they preferred to integrate in a lesson plan. Pilot study of the task was also conducted with three recent graduates of the same program as they completed the same courses with the targeted PSTs to finalize the data collection instrument. The modifications included directing phrases were added to questions related to the strength and weakness of the lesson plan in order to keep PSTs in focus.

During the task implementation, PSTs were expected to realize the incompleteness and improperness of the lesson plan, write the strength and weakness of the plan considering the lesson design, mathematics content, objectives and assessment part of the lesson plan. They were also asked to suggest some ways to improve the plan in line with weaknesses they found. Participants gave written answers to the questions; they did not implement the lesson plan in a real classroom environment.

The task was implemented in the courses taken by 2<sup>nd</sup> year, 3<sup>rd</sup> year, and 4<sup>th</sup> year PSTs. Preservice teachers who attended the courses were asked if they would like to participate in the study. The researchers explained that their interest was about how PSTs would redesign the given lesson plan which they would conduct in a real class setting. Participants of the study completed the task between 40-60 minutes. Data were analyzed through content analysis. PSTs' formative assessment practices were categorized based on the framework in Table 1. PST's expressions which implied formative assessment were grouped under the five strategies indicated in the formative assessment framework. Participants' comments related to the improperness of the lesson plan were also examined considering improperness criteria indicated above. Peer review strategy was utilized in order to ensure the categorization.

## **Findings**

### **Incompleteness of the Lesson Plan**

Findings of the study indicated that there was an increase in the emphasis on integrating formative assessment strategies in the lesson plan as the students progressed in the program. However, participants did not address all formative assessment strategies together in any year level. For instance, participants did not mention using the strategy "activating students as the owners of their own learning" (self-assessment). Besides, "activating students as instructional resources for one another" strategy (peer-assessment) was integrated into the lesson plan by only two 2<sup>nd</sup> year PSTs from the total of 111 participants. This shows that 3<sup>rd</sup> or 4<sup>th</sup> year PSTs did not propose to integrate self- and peer-assessment strategies in the lesson plan. Participants also did not make any comment about the integration of the "providing feedback that move learners forward" strategy to the lesson plan.

A total of 21 PSTs suggested asking questions for "engineering effective classroom discussions". Six percent of the 2<sup>nd</sup> year (n=3), 22% of the 3<sup>rd</sup> year (n=8), and 37% of the 4<sup>th</sup> year (n=10) PSTs recommended to include question-answer part in the lesson plan. 2<sup>nd</sup> and 3<sup>rd</sup> year PSTs made general comments about the necessity to include the questions: "questions that will guide the teacher during

the implementation of the lesson plan and students' possible answers to these questions need to be added to the lesson plan" (3<sup>rd</sup> year PST-3P16). On the other hand, most of the 4<sup>th</sup> year PSTs specified the part of the lesson plan where they would include the questions and explained the reasons why they needed to include them. Some 4<sup>th</sup> year PSTs also exemplified these questions. For instance, one of them, 4P27, criticized the lesson plan and improved it as follows:

First of all, at the beginning of the lesson plan, questions such as "What is the meaning of the fraction?", "What do numerator and denominator mean?" need to be asked in order to activate students' previous knowledge.

A few participants also emphasized the necessity to include classroom observation to be able to "engineer effective classroom discussion" in the lesson plan. Four percent of the 2<sup>nd</sup> year (n=2), 11% of the 3<sup>rd</sup> year (n=4), and 7% of the 4<sup>th</sup> year PSTs (n=2) suggested observing students while they were studying on the activity in order to elicit their learning. According to them "the teacher could observe each student while they were studying on the activity individually. In this way, assessment of students' progress would be easier" (3P26).

Six percent of the 2<sup>nd</sup> year (n=3), 11% of the 3<sup>rd</sup> year (n=4), and 15% of the 4<sup>th</sup> year PSTs (n=4) recommended to include some sentences which may imply the clarification of learning intentions in the lesson plan. For instance, one of the 2<sup>nd</sup> year PSTs, 2P8, suggested to "give more information to the students related to the lesson content at the beginning of the activity." She thought that "giving information about the activity would lead to an increase in the number of students who successfully finished the activity" (2P8). On the other hand, not any participants gave suggestion to include success criteria in the lesson plan for neither the classroom activity nor the questions in the assessment part.

### **Improperness of the Lesson Plan**

Findings of the study showed that participants who took measurement and assessment course and methods of teaching courses were more successful in detecting that there was not any activity in the lesson plan related to one of the lesson objectives. While only 11% of the 2<sup>nd</sup> year PSTs (n=5) noticed this improperness, 32% of the 3<sup>rd</sup> year (n=12) and 30% of the 4<sup>th</sup> year (n=8) PSTs underlined this improperness and indicated that "students cannot achieve the objective at the end of the lesson" (3P20) "since there were not any activity or question in the lesson plan related to it" (3P3). Although some PSTs realized that there was an inconsistency between the objectives and lesson content, less number of PSTs discerned the inconsistency between objectives and questions in the assessment part of the lesson plan in any year level. Six percent of the 2<sup>nd</sup> year (n=3), 22% of the 3<sup>rd</sup> year (n=8) and 15% of the 4<sup>th</sup> year (n=4) PSTs noticed that questions in the assessment part were not sufficient and qualified to understand whether the students achieve the all objectives of the lesson. Another criterion for the improperness of the lesson plan, immeasurable and unobservable lesson objective, was detected more by 2<sup>nd</sup> year PSTs. While only one 4<sup>th</sup> year PST (4%) and three 3<sup>rd</sup> year PSTs (8%) realized this improperness, six 2<sup>nd</sup> year (13%) PSTs addressed the improperness and emphasized that "objectives need to be measureable. In the contrary case, how we can understand that students achieve the objectives?" (2P43).

Almost all participants made comments about the weak structure of the questions in the assessment part in all year levels; however, they proposed different reasons. In general, participants criticized the

type of the questions, true-false questions, since students have 50% chance to answer the question correctly. They also indicated that “asking only this type of question was not sufficient to assess students understanding of equivalent fractions” (4P26). Almost half of the 4<sup>th</sup> year PSTs (44%, n=12) suggested to include questions about modeling the fractions in the assessment part of the lesson plan. Some PSTs also recommended to ask students explain the reasons for why they gave “true” or “false” answer to the questions. For instance, 4P10 explained her reasoning in suggesting these kinds of open ended questions in this way:

Questions asking students draw some models could have been included in the assessment. Or, students could have been asked to explain why they preferred to answer the question as “true” or “false”. Only in this way, a teacher can elicit students’ misunderstandings or misconceptions.

Especially 3<sup>rd</sup> year PSTs underlined the fact that the questions in the assessment part did not assess all lesson objectives and they suggested to include question which were designed to assess all lesson objectives in the assessment part of the lesson plan (22%, n=8). Only two 2<sup>nd</sup> year PSTs emphasized that the assessment part of the lesson plan needs to be graded. However, none of the participants mentioned the necessity to include the rubric for the questions in the assessment part which was one of the reasons for the improperness of the given lesson plan.

## Discussion and Conclusion

Finding of the study revealed that PSTs seemed to make little or no benefit of formative assessment strategies which could be utilized to enhance students’ learning process. None of the participants preferred to integrate self-assessment strategy into lesson plan and only two 2<sup>nd</sup> year PSTs mentioned the necessity of peer assessment. The reason for not addressing these strategies might be the preservice teachers’ thoughts that students were not able to assess their peers’ and their own performances objectively (William, 2007). They might also perceive assessment as only their responsibility since they believed that only they would have expertise to assess students’ learning (Sadler, 1989). PSTs also did not refer to provide feedback to students. This might be due to the nature of the data collection instrument. Since students’ possible responses were not provided to the participants, they might not need to give feedback to students in order to enhance their learning.

Questioning and observing are the most used methods for gathering information about students’ progress (Antoniou & James, 2014). Although more 3<sup>rd</sup> and 4<sup>th</sup> year PSTs suggested to include questions and observation in the lesson plan, the number of participants who took attention to these strategies was very limited. This little emphasis on including questions in the lesson plan might be due to the fact that PSTs thought that they did not need to write questions in the lesson plan since they would keep them in their mind. However, when the questions were written before the instruction began, teachers could have an opportunity to explore particular strategies for increasing students’ attention to the key mathematical concepts (Black et al., 2003). Moreover, the reason more 3<sup>rd</sup> and 4<sup>th</sup> year PSTs suggested to include question in the lesson plan compared to 2<sup>nd</sup> year PSTs might be that they had more experience on the preparation of lesson plan and conducted more discussion of classroom activity in the lesson plan and lesson flow. Since 4<sup>th</sup> year PSTs also had opportunity to observe their mentor teachers’ instruction in school assessment course, they might have specified the part of the lesson plan where they would include the questions and they explained the reasons why

they needed to include them. Moreover, PSTs did not reflect explicitly on making observation while students were working on the class activity. Similarly, teachers have been reported to focus mainly on the learning product and did not monitor students' learning processes in their plans (Ruys, Van Keer, & Aelterman, 2012).

Findings of the study also indicated that not many participants were able to detect the improperness criteria of the lesson plan in general. Participants who took measurement and assessment course and methods of teaching courses were more successful in detecting the inconsistency between both objectives and classroom activity, and objectives and questions in the assessment part. However, still the number of PSTs who detected this improperness was very low. Although ensuring the consistency between objectives-classroom activity and objective-plan's assessment is one of the basic concerns that should be taken into account in lesson planning (Moss & Brookhart, 2009; Ruys, Van Keer, & Aelterman, 2012), and necessity of consistency between those has been emphasized especially in instructional principles and method, and measurement and assessment course, such limited number of participants who emphasized on this feature was unanticipated. Additionally, more 2<sup>nd</sup> year PSTs detected one of the other reasons for the improperness of lesson plan, immeasurable and unobservable lesson objective, than 3<sup>rd</sup> and 4<sup>th</sup> year PSTs. Since 2<sup>nd</sup> year PSTs recently have learnt how to write lesson objectives in instructional principles and method course, they might have been aware of this improperness. This might also show that 3<sup>rd</sup> and 4<sup>th</sup> year PSTs have not internalized why the objectives were supposed to be measureable and observable through their university education despite the strong emphasis on these characteristics.

Majority of the PTSs (regardless of their year levels) were able to detect the improperness of the assessment part resulting from the structure of the questions. Participants mainly proposed that they could not know if the students achieved the objectives or not with true-false type questions. Especially 4<sup>th</sup> year PSTs proposed to add different types of questions to the assessment part. The reason for suggesting to include question in the assessment might be due to their awareness of the requirement of the alignment between objectives and the questions in the assessment. Additionally, participants did not specify any success criteria or rubric for the assessment part of the lesson plan. The nature of the questions in the assessment part might be the reason for omitting the success criteria. PSTs might not need to include any rubric for the scoring since the questions were in true-false type. Another reason for not including rubric in the lesson plan might be PSTs' thoughts about the usage of assessment. They might have preferred not to score students' work and use it for formative purposes.

Although instructional principles and method, and measurement and assessment course provided necessary knowledge to the PSTs about formative assessment, PSTs had difficulty in integrating intended formative assessment strategies in the given lesson plan. PSTs who took methods of teaching courses and school experience course (3<sup>rd</sup> and 4<sup>th</sup> year PSTs) were more successful than 2<sup>nd</sup> year PSTs in detecting incompleteness and improperness of the lesson plan. Preparing lesson plan, having opportunity to discuss it with their peers in methods of teaching courses and observing mentor teachers' instruction in middle schools in school experience course might help PSTs to see the whole picture of the lesson plan in terms of the usage of formative assessment strategies. Also having these experiences might provide PSTs to criticize the lesson plan with different perspective.

# An assessment of non-standardized tests of mathematical competence for Norwegian secondary school using Rasch analysis

Morten Riise Klegseth, Eivind Kaspersen and Trygve Solstad

Norwegian University of Science and Technology, Faculty of Social and Educational Sciences,  
Department of Teacher Education, Trondheim, Norway

[Morten-Riise.Klegseth@ou.trondheim.kommune.no](mailto:Morten-Riise.Klegseth@ou.trondheim.kommune.no); [eivind.kaspersen@ntnu.no](mailto:eivind.kaspersen@ntnu.no);  
[trygve.solstad@ntnu.no](mailto:trygve.solstad@ntnu.no)

*Do non-standardized, publisher-provided tests for lower secondary school provide valid and reliable measures of mathematical competence? We analysed a sample of items pooled from tests accompanying three different Norwegian textbooks using Rasch analysis. The pooled sample of items was found to be sufficiently unidimensional for measuring function competence, with four strands of sub-competencies in accordance with theory. The competence associated with an increasing difficulty of items could be qualitatively characterised by shifts from a) identifying through constructing to reasoning about representations, b) using visual to using algebraic representations, and c) local to global interpretations of functions. While the individual tests differed substantially in the distribution of items across strands of mathematical competence, minor adjustments to the combined instrument were sufficient for providing a valid and reliable measure of mathematical competence.*

*Keywords: Competence, assessment, rasch, functions.*

## Introduction

### Background

Teachers rely strongly on written tests when determining final grades for secondary school pupils (Brookhard, 1994). In Norway, final grades are to a large degree based on results on non-standardized midterm exams and shorter tests provided by textbook publishers (Prøitz & Borgen, 2010). Publisher-provided tests are composed by experienced textbook authors without explicit reference to a theoretical framework for the mathematical competence the tests aim to assess. Because mathematical functions are central to the field of mathematics and to the Norwegian secondary school curriculum, and because they are typically introduced in the 10<sup>th</sup> grade, the topic constitutes a relevant and convenient source of information about how such tests are composed and what they measure. In this study we asked a) how competence in linear functions is operationalised in tests accompanying Norwegian mathematics textbooks, and b) to what extent these tests provide valid and reliable measures of mathematical competence.

### Theoretical framework for competence in mathematical functions

As a starting point for describing mathematical competence, we took the widely used Danish KOM model, which distinguishes eight partially overlapping mathematical *competencies* (Niss & Jensen, 2002). Briefly, these competencies are i) Mathematical thinking, ii) Mathematical problem solving and -posing, iii) Mathematical modelling, iv) Mathematical reasoning, v) Handling mathematical representations, vi) Handling mathematical symbols and formalisms, vii) Mathematical communication, and viii) Using aids and tools.

The tests we analysed were dominated by questions concerning transformations of different representations of functions, warranting a further characterization of this competency. Representations form the foundation of many theoretical frameworks for mathematical competence and have been central to describing competence in functions. O’Callaghan (1998) presents a model with four main components: 1) *Modelling*, the transformation from a problem situation to a mathematical representation using functions, 2) *Interpretation*, the transformation from a mathematical representation of a function to the description of a problem situation, 3) *Translation* between representations of functions, like symbols, tables, and graphs, 4) *Reifying*, the creation of a mental object from what was initially perceived as a process or procedure, and 5) *Procedural skills* for operating within a representation system.

### **Levels of competence**

The present manuscript focuses on the role that textbook tests have in determining students’ final grades. These tests are typically administered after each mathematical topic has been covered in class and can be considered high stakes in the sense that they collectively make up part of the basis for a teacher’s end-of-school assessment. However, these tests often serve formative as well as summative purposes. While the summative aspect differentiates students according to their levels of competence, qualitative characterizations of each level of competence within a competency can both address issues of test validity and be useful in a formative perspective on assessment.

The perceived difficulty of a question about mathematical functions has been shown to depend on the cognitive demand of providing a valid answer to a problem. In particular, *interpreting* or *recognizing* properties of a given representation or statement is easier than *recalling* or *constructing* a solution to a problem when a target representation is not given. *Explaining* why a solution is valid typically requires the student to explicate relations between multiple representations and is perceived as more difficult than identifying and constructing valid representations (Leinhardt et al., 1990; Nitsch et al., 2015).

Representations of functions and transitions between representations can be interpreted from a local or global perspective. Whereas local interpretations of a function involve accessing single values of the representation, global interpretations involve reasoning about how the function behaves as a whole or within certain intervals of the domain. Global interpretations are important for accessing more advanced mathematics and are associated with higher levels of mathematical competence (Leinhardt et al., 1990; Gagatsis & Shiakalli, 2004; Duval, 2006; Bossé et al., 2011).

These perspectives on what characterizes different levels of competence served to aid our analysis of the test items from the non-standardized textbook tests.

## **Methods**

### **Selection of test items**

Three tests accompanying 10<sup>th</sup> grade textbooks from three major Norwegian publishers were selected as a source of common test items in Norwegian schools. When two or more tests contained very similar items, only one item was selected for our instrument. Items that did not address the subject of linear functions were excluded from the study. One item was excluded because it could not be

faithfully translated into digital form. Items requiring a global interpretation of functions were missing from the original tests, and we added two items in order to assess this category of competence. After this selection process our pooled test consisted of 31 test items.

### **Modification of test items**

After a pilot study, Rasch analysis identified some items as unreliable. In particular, multiple choice items did not provide good fits to the Rasch model and were converted into explanation items. One original item used specific numbers that produced ambiguous answers, and a new set of more suitable numbers was chosen. For a few items, we adjusted the specific numbers used in order to obtain a more uniform distribution of item difficulties in the instrument as a whole.

### **Categorization of test items**

The test items were categorized according to the theoretical frameworks discussed in the introduction. While no items fell into the ‘reification’ category, several items asked about specific concepts. Reification was therefore substituted with a separate category for Concepts, and we used the following categories for the analysis: Interpretation, Translation, Modelling, Concepts, Coordinates and Others. The three first categories were generated directly from the theory of competence for functions. Concepts can be considered part of mathematical thinking in the KOM framework (Niss & Jensen, 2002, p. 47), and coordinates can be considered a part of “symbols and formalisms” in the KOM framework (Niss & Jensen, 2002, p. 58). Items in the “others” category were excluded from the study as they were not directly related to competence in linear functions, like items requiring competence in nonlinear functions, solving equations, and general competence with digital tools.

An anticipation of item difficulty was estimated (“easy”, “medium”, or “difficult”) for each item based on whether the item required a) identification or interpretation of a given solution, b) construction of a valid solution, or c) an explanation for a mathematical statement (Nitsch et al., 2015; Leinhardt et al., 1990). The anticipated difficulty was adjusted according to whether the item required a) a local or global interpretation of the given function, and b) one or multiple transformations between representations of the given function.

### **Participants**

A convenience sample of fourteen school classes with a total of 250 tenth grade pupils from 5 out of 13 secondary schools in the city of Trondheim, Norway, participated in the study. All pupils had completed classroom instruction in linear functions between one week and two months before they participated in the study. Participation was voluntary, and all answers were anonymous.

### **Data collection**

The test items were digitized and answers to the items were collected using a web platform developed at the Department of Teacher Education, NTNU. After a 5-minute presentation of the testing tool and informed consent, pupils had 55 minutes to complete the test. Test items were presented in randomized order. If no answer was given to a test item, the answer was coded as “missing data”.

## Analysis

As most items in the tests asked for a single correct answer, each item was scored either 0 or 1 point (dichotomous model). Quantitative data was analysed with the Rasch model (Rasch, 1960) using the Winsteps software (Linacre, 2017). In the Rasch model, the probability that person  $v$  scores 1 point on item  $i$  depends on the difference between the ability of person  $v$ ,  $\beta_v$ , and the difficulty of item  $i$ ,  $\delta_i$ , according to

$$P\{X_{vi} = 1 | \beta_v, \delta_i\} = \frac{e^{(\beta_v - \delta_i)}}{1 + e^{(\beta_v - \delta_i)}}$$

Winsteps implements the joint maximum likelihood estimation (JMLE) algorithm for estimating the parameters of this model, and principal component analysis (PCA) of normalized residuals for investigating the dimensionality of the dataset.

## Validity

Assessment of the validity of the instrument was based on the framework presented in Wolfe and Smith (2007) which expands on Messick (1995). Here, we considered the following six aspects of validity: *i) Content* (e.g. relevance, representativeness, and technical quality), *ii) substantive* (e.g. theoretical foundation), *iii) structural* (e.g. evidence of unidimensionality), *iv) generalizability* (e.g. generalization across sample and context), *v) consequential* (e.g. fairness and possible biases), and *vi) interpretability* (e.g. the relationship between quantitative measures and qualitative meaning).

## Results

### Classification of item competence

We collected test items from three publisher-provided tests in functions for Norwegian secondary school. The items were classified into five competence categories and assigned an anticipated level of difficulty (depending on cognitive demand, number of representational transformations, and local vs global perspective on functions). While the combined set of items covered a broad range of competence categories, individual tests differed substantially in their emphasis on each competence category (Table 1). In particular, tests B and C put opposite emphasis on interpretation, translation and concepts, while items from test A were more evenly distributed among the categories.

Test	Concept	Interpretation	Translation	Modelling	Coordinates	Excluded
A	4	4	5	2	1	5
B	0	7	1	3	1	3
C	4	1	6	4	4	5

**Table 1: Number of items in each competence category for each of the tests in the study.**

### Measurement properties

In general, the data fit well with the Rasch model, contributing to the instrument's content validity (Wolfe & Smith, 2007). Person reliability, analogous to Cronbach's alpha, was 0.86. Item infit mnsq

was  $1.01 \pm 0.18$  (mean  $\pm$  std) and item outfit mnsq was  $0.9 \pm 0.34$  (mean  $\pm$  std), which means that the variance in pupils' responses to single items generally fit well with the Rasch model (infit mnsq = outfit mnsq = 1).

**Figure 1. Competence level of pupils (blue boxplot) and item difficulty (red boxplot) on the same logit scale. Boxplots indicate 10<sup>th</sup>, 25<sup>th</sup>, 50<sup>th</sup>, 75<sup>th</sup> and 90<sup>th</sup> percentiles.**

The item difficulties ranged from  $-4.9$  to  $3.3$  logits, but the distribution of items was uneven with 28 out of 31 items between  $-1.7$  and  $2.6$  logits (Figure 1, red boxplot). This contrasted with the distribution of pupil achievement level: only about half (52%) of the pupils achieved within this range of item difficulties, and almost 75% of pupils achieved below the mean item difficulty (Figure 1, blue boxplot). The low attainment might be related to the time of testing and the perceived distance to final exams.

Only two items were positioned to discriminate achievement levels below the  $-1.7$  logit mark where 42% of pupils were measured. These items might be considered at the entry level to competence with functions, and as a tool for summative assessment the instrument distinguishes well between pupils above that competence level. However, the large gaps between easy items, producing an abundance of low test scores, leaves a large proportion of students without feedback about their competence level beyond an unintended subtext of failure. From the view of formative assessment, the scarcity of easy items detracts from the instrument's content and consequential validity (Wolfe & Smith, 2007).

Item difficulty was largely invariant to the pupils' achievement level, as determined by comparing the difficulty level of each item between the highest achieving and lowest achieving pupils.

Pupil achievement level affected the difficulty of only 2 out of the 31 items (at the  $p = 0.0016$  level; Bonferroni corrected for multiple comparisons from  $p = 0.05$ ), contributing the instrument's generalizability validity (Wolfe & Smith, 2007). The first of these items favoured high-achieving pupils and was the only item involving a function with negative slope. The second item favoured low-achieving students by unintentionally allowing the zooming in on a graph to read off the solution directly rather than reasoning about it.

### Empirical categories of competence

The competence categories were taken from theoretical frameworks for competence with functions. To investigate if these categories could be identified in the empirical data, we conducted a PCA on standardized residuals of the data (Linacre, 2017). PCA identified two contrasts with potential subdimensions. The first contrast (eigenvalue = 2.4) clearly separated Interpretation items (the six items with the highest positive loading) from Translation items (the six items with the highest negative loading). In addition, all 13 items in the cluster with negative loading included symbolic expressions. The second contrast (eigenvalue = 1.9) separated the full set of five Concept items

together with the single coordinate item from the main dimension of the instrument. The Modelling items did not deviate from the main dimension defining competence levels for linear functions.

While 49% of the variance in the data could be explained by the measures, the additional variance explained by the four clusters combined was around 7%, which can be usefully considered sub-dimensions of the main variable. Taken together, the instrument can be considered unidimensional for measuring competence in linear functions, which adds to its structural validity. At the same time, the dimensionality analysis lends empirical support to the notion that competence in linear functions is composed of four strands, each dominated by one of the four main competence categories Concept, Interpretation, Translation, and Modelling. This correspondence between empirical clusters and theoretical foundation speaks to the instrument's substantive validity.

### **Empirical levels of competence**

What is the qualitative meaning of the quantitative measure along the competence scale?

*First*, the distribution of item difficulty did not differ significantly between competence categories, either in variance ( $p = 0.15$ ; Levene's test) or mean difficulty ( $p = 0.13$ ; one-way ANOVA; Figure 2). However, the two most difficult items in the Interpretation category were added to the original items because a global perspective of functions was missing from the original tests. Without these two items, the mean difficulty of Interpretation items was significantly lower than for items in the other categories ( $p = 0.01$ ; one-way ANOVA).

Two items in the Interpretation category stood out as easier than other items. These items asked pupils to read off a value in a coordinate system and count the number of constant parts of a graph. Arguably, both items could be classified as prerequisite for, rather than part of, graphical representations of functions. At the same time, the competence of as much as 40% of the students were estimated to be within this prerequisite level of function competence, challenging the validity of the test as a formative tool. Beyond the fact that both students and teachers are deprived of the positive effects of feedback for learning, close-to-zero test scores counteract a fair assessment of competence and are potentially harmful to students' motivation for learning (e.g. Schinske & Tanner, 2014). To fulfil its role as a formative tool and guide low-attaining students towards proficiency with functions, the test set should be supplemented with items about prerequisite competencies for functions.

*Second*, the predicted item difficulty fit well with the empirically estimated item difficulties (different colours in Figure 2). Three exceptions were of interest. These three items were measured to be more difficult than anticipated from theory and shared a pattern in the kinds of mistakes pupils made in answering them: The second and third most difficult Concept items (see Figure 2) asked pupils to identify the slope of a function expression. Most pupils either a) mistook the constant term for the slope, or b) included the variable with the slope in their answers ( $\frac{x}{4}$  and  $3x$ ). These very common mistakes resulted in higher-than anticipated measures for these two items. The unexpectedly high estimate of the coordinate system item was also due to a widespread mistake. The item asked pupils to plot a line between two given points, and a surprisingly large proportion of pupils interpreted the two coordinates as four points in the coordinate system instead of two.

**Figure 2: Item difficulty plotted by competence category on x-axis and coloured by anticipated difficulty. Green: easy item, blue: intermediate item, red: difficult item.**

*Third*, 8 out of the 9 items with difficulty less than -1 logit did not concern symbolic expressions. The one item that did was the easiest Modelling item, and asked pupils to form an equation rather than a function from a written context. The item could be solved using an additive strategy without noticing a functional relationship between two variables. -1 logit seems to mark a threshold above which competence with the algebraic symbol system for functions is required. 58% of the pupils in this study scored below the level requiring competence with symbolic expressions for functions.

The qualitative stratification of items along the difficulty scale

gives the instrument interpretability validity (Wolfe & Smith, 2007). The stratification is also useful for formative assessment, but only for pupils that have acquired a minimum level of competence with functions.

## Conclusions

We have presented an analysis of a test pooled from three publisher-provided tests of competence in linear functions. The analysis shows that, with minor modifications to some test items, the test set as a whole is a reliable and valid measurement instrument that can be considered one-dimensional for its intended purpose yet consists of empirically identifiable strands of competence that correspond closely to the theoretical framework for mathematical competence outlined in the introduction.

The study suggests that if items are sampled in a balanced manner across both different subdimensions and difficulty levels according to the theoretical framework, calibrated standardized tests might not be necessary to obtain reliable and valid summative assessment of mathematical competence on small scale tests for secondary school. However, adding items on topics prerequisite to competence with functions would strengthen the instrument's value as a formative tool.

### Introduction

Large scale assessment in education often aims at measuring proficiency in subject areas, thus considering latent variables that are not directly observable but defined through a theoretical framework and operationalized through standardized tests. For each subject area, a numerical test score (proficiency score) is typically computed in order to locate the students on the variable continuum (learning metrics or proficiency scale) defined by the test items, i.e. the proficiency score quantifies how much of the measured variable (for example mathematics ability) is present (Turner, 2014). Reporting test results only in terms of numerical test score, however, does not provide substantial information on what students typically know and can do. A substantial description of the location along the proficiency scale is needed in order to support practitioners in interpreting test results and in order to convert them into effective teaching practices (van der Linden, 2017).

In the last years a growing number of national (e.g., National Assessment of Educational Progress, MEETS NAEP GUIDELINES) and international (Program for International Student Assessment, PISA; Trends in International Mathematics and Science Study, TIMSS; Progress in International Reading Literacy Study, PIRLS) testing programs has been developing descriptive proficiency scales, in order to report test results not only as proficiency scores but also in terms of described proficiency levels. The goal is to illustrate what the scores represent in terms of students' skills, understanding and competencies (van der Linden, 2017). This goal has been recently pursued by the Italian National Institute for evaluation of the education and training system (INVALSI), that yearly carries out standardized tests to assess students' achievement in mathematics and reading (i.e. reading comprehension and grammatical knowledge), and to evaluate the overall quality of the educational offering of schools and vocational training institutes.

### INVALSI experience

INVALSI returns data as descriptive proficiency levels for reading (reading comprehension and grammatical knowledge) and mathematics, for the first time in the school year 2017-2018. Basing on the INVALSI Reference Framework, and coherently with the National Guidelines for the Curriculum's goals (MIUR 2012), proficiency scales have been developed through an extensive Rasch item bank, administered by computer based tests (CBT) ([https://invalsi-areaprove.cineca.it/docs/2018/INVALSI\\_tests\\_according\\_to\\_INVALSI.pdf](https://invalsi-areaprove.cineca.it/docs/2018/INVALSI_tests_according_to_INVALSI.pdf)). Five proficiency levels have been identified considering the distribution on the same scale of both the items' difficulty and

the students' ability (Desimoni, 2018). The five levels have been described basing upon the items' content. The consistency between the item ordering basing on the psychometric data and the item ordering predicted from theory represents a fundamental aspect for the scale validity, an issue widely investigated during the scale construction.

The present contribution will investigate the psychometric and qualitative-educational properties of a pool of sample items (Garuti et al., 2017), from the INVALSI Item Bank, in order to better investigate this aspect: which are the item properties highlighted from the concurrent psychometric and qualitative teaching analyses? Beyond an overview of the development of the mathematics' described proficiency scale, the study will focus on five items, of an increasing level of difficulty (scaled from 1 to 5), and referring to same content (Numbers) and to the same learning goal (Operation between numbers and numbers ordering), in order to identify the typical item characteristics determining its placement within a level. Specifically, which are the cognitive obstacles that students need to overcome to pass, for instance, from level 3, "link and integrate multiple fundamental pieces of knowledge concerned with processing, ordering between rational numbers and representations of mathematical objects" to level 4, "integrate and make connections between basic pieces of knowledge where the relationships are provided implicitly or derived from a representation".

From a practical perspective, we found interesting results, that might be supportive to the development of new items for the INVALSI Item Bank. Finally, we also discuss potential implications of our results in the teaching process.

## Background to the Study

In Ireland, all students sit a summative state examination known formally as the Leaving Certificate (LC) at the end of Senior Cycle (upper secondary level). The LC acts as a gatekeeper to tertiary level education with students awarded points based on their six best graded subjects. Different points are also awarded pending the level of which the subject was studied. For example, the majority of subjects have two levels. The most challenging level is Higher Level (HL - often referred to as Honours) and the next level down is Ordinary Level (OL - often referred to as Pass). Since 2012 mathematics has been assigned a special status within the Irish post-primary school curriculum with the introduction of a Bonus Points initiative (BPI). Students are now awarded an extra 25 points in their LC examination results if they achieve a passing grade at HL. The awarding of these extra points was introduced to encourage students to study mathematics at HL. Such incentive schemes for studying mathematics and improving student performance in the subject are not a new phenomenon. Similar schemes exist in Australia and Israel (Treacy, 2018).

In Ireland while the numbers opting for HL mathematics have nearly doubled since the introduction of the BPI, anecdotally there have been many mixed reviews. Hence, while there have been calls in some quarters to extend this initiative to other subjects, it is important that the impact of the BPI on the study and assessment of mathematics is first appraised. This paper investigates the advantages and disadvantages associated with the BPI from the perspective of mathematics teachers (n=266) and aims to address the following research question: What are mathematics teachers' perceptions of the Bonus Points Initiative as an incentive in state examinations?

## Methodology

The methodology of this study involved the distribution of a questionnaire to a representative sample of HL mathematics teachers in Irish post-primary schools (n = 723). The instrument was designed specifically for this study and was developed by the authors with the assistance of an advisory group involving five experienced post-primary mathematics teachers. It comprised of four main sections. Section 4, which is the focus of this submission, inquired of teachers' perceptions of the BPI through a series of multiple choice and open-ended questions. The finalized questionnaires were distributed (two to a stratified sample of 400 post-primary schools) in early April 2018. The response rate was 266 second level teachers (approx. 33%). The open-ended questionnaire data was analysed thematically in two stages. Firstly, the first coder coded the two sets of data (perceived advantages

and disadvantages) himself two weeks apart, and the *intra*-coder agreement percentages were equally high (> 90%). The second coder subsequently coded around a third of each dataset and once again the inter-coder agreement percentages were > 90% for the perceived advantages and disadvantages, highlighting that the coding frameworks that we developed for this study's analysis were reliable.

## Findings and Discussion

Findings from both the qualitative and quantitative data in this study indicate that teachers hold many mixed opinions regarding the BPI. While 46% of respondents indicated that they agree with the BPI, the rest were either not sure or did not agree. The main advantage of the initiative was that it increased uptake and perseverance of mathematics at HL. However, while the numbers taking HL may have increased, respondents noted some concerns about the standard of students now persisting at HL. A greater proportion of students that would have typically attempted the OL examination, were it not for the BPI, were now attempting the HL examination and thus there was an increase in those achieving low grades (SEC 2015). There were also fears that the LC HL mathematics examination would be 'dumbed down' to cater for the surge in students now taking it. It was feared that "*Students of a stronger mathematics ability may not be extended to the same degree*".

However, while these concerns are real, there were also many advantages of the BPI which were noted by the participating teachers. The second most cited benefit was that it rewarded students for the time and effort required for the course. Concern has long been expressed at the workload and timeframe of the LC HL mathematics curriculum in Ireland (Cosgrove et al., 2013). In addition to the workload and timeframe, a study carried out by Smyth, Banks, and Calvert (2011) found that mathematics is considered to be among the top five most difficult LC subjects. Thus the BPI rewards students for their exertions and supports the view that mathematics is not 'just another subject' (McDonagh & Quinlan, 2012).

However, the findings of this study indicate that while there are clear advantages to the special status that the BPI has given mathematics within the Irish post-primary school curriculum, there was also a number of interlinking disadvantages which must be considered if such incentive schemes are to be maintained, and indeed expanded.

## Introduction

Iran has a centralized education system, with national textbooks that are used for every school subject, including mathematics. In this education system, the assessment regulation and educational policy determine what type of student assessment teachers carry out. The latest version of this assessment regulation in primary school is called *Descriptive Assessment*. This is an approach for evaluating students' achievement by collecting and documenting evidence regarding their learning and performance. Teachers can collect this evidence through different methods including observations of students during the classes, interviews, students' portfolios, performance tasks, and various kinds of tests (Ministry of Education [MoE] & Organization for Educational Research and Planning [OERP], 2011; Supreme Council for Education [SCE], 2009). In this poster, we investigate the research question: *To what degree have the suggested assessment methods from the Descriptive Assessment regulations been implemented in the classroom practice of Iranian primary mathematics teachers?*

## Method

For this we performed a multiple case study of which we present the first results at CERME11. We provide data on the assessment practice of seven Grade 4 female mathematics teachers (age  $M=46$ , [min, max] = [38, 54]) in Tehran. These teachers were first contacted by telephone and agreed to participate in this research. The data we used for this case study originated from four sources:

1. The teachers responded to an Iranian version of a questionnaire on teachers' assessment practice in mathematics education (Veldhuis, Van den Heuvel-Panhuizen, Vermeulen, & Eggen, 2013).
2. We interviewed the teachers individually by asking them to explain answers they provided in the questionnaire and to discuss their lesson plan for the lesson that would be observed.
3. The ensuing lesson on the development of first notions of probability was observed and videotaped.
4. We conducted a post-observation interview in which the teachers were asked to reflect on their taught lesson.

In the analyses of these data, we focused on the teachers' use of assessment methods and compared that to their prescribed use in the regulations on *Descriptive Assessment*. In two important documents,

the Teacher's Guidance for *Descriptive Assessment* (MoE & OERP, 2011) and the Academic Assessment Regulation for Primary School (SCE, 2009), a variety of assessment methods is suggested such as, observing students in class, asking questions in class, administering written test, having individual assessment conversation, offering performance tasks and having students working on project. As described in the guidelines, performance tasks are an instrument for measuring students' activity and attempts in practical and observable situations. Performance tasks focus on both students' knowledge and skills. Asking students to write a mathematics problem and its solution is an example of a performance task.

## Result and conclusion

Currently, the data of our study have not yet been fully analyzed, therefore in this poster proposal, we only include a description of one assessment method (see Table 1, teachers' use of performance tasks). In the table, the information from the four data sources are combined to show whether teachers reported or showed that they use a particular type of performance task for a particular purpose and with which frequency.

**Table 1: Teachers' practices and beliefs about using performance tasks**

Performance task		T.1	T.2	T.3	T.4	T.5	T.6	T.7
Type	Designing something	Ü		Ü	Ü	Ü		
	Using a tool	Ü	Ü	Ü			Ü	Ü
	Giving a presentation	Ü	Ü		Ü	Ü		Ü
	Writing a text			Ü	Ü	Ü	Ü	
	Participating in a project							
Purpose	To improve students' learning skill	Ü	Ü	Ü				
	To motivate students	Ü						Ü
	To involve students in the teaching process		Ü		Ü			
	To make teaching efficient						Ü	
Frequency	More frequently than monthly					Ü		Ü

We expect to have finalized our analyses before CERME11. So, at the conference we can present the results in full detail and answer the research question.

# Developing and evaluating an online linear algebra examination for university mathematics

Christopher Sangwin<sup>1</sup>

<sup>1</sup> University of Edinburgh, School of Mathematics; C.J.Sangwin@ed.ac.uk

*In this paper I report development of an automatically marked online version of a current paper-based examination for a university mathematics course, and the extent to which the outcomes are equivalent to a paper-based exam. An online examination was implemented using the STACK online assessment tool which is built using computer algebra, and in which students' answers are normally typed expressions. The study group was 376 undergraduates taking a year 1 Introduction to Linear Algebra course. The results of this experiment are cautiously optimistic: a significant proportion of current examination questions can be automatically assessed, and the quantitative outcomes are moderately correlated with the paper examination.*

*Keywords: Mathematics, undergraduate study, high stakes tests.*

## Introduction

To what extent can we produce an automatically marked version of a paper-based examination for methods-based university mathematics courses using contemporary technology? To what extent are the outcomes of this exam equivalent to the outcomes of a paper-based exam? In this paper I report a pilot to develop, use, and evaluate an online examination for a university linear algebra course.

My work is based upon the epistemological position that to successfully automate a process it is necessary to understand it profoundly. It follows that automation of a process necessitates the development of a certain kind of understanding and we learn a lot about the underlying process through automation. Assessment provides students with challenge, interest and motivation: assessment is a key driver of students' activity in education. To many students mathematics is defined in a large part by what we expect students to do in examinations, (Burkhardt, 1987).

The STACK online assessment tool (Sangwin, 2013) is built using computer algebra and students' interactions move significantly beyond multiple choice questions with their well-known difficulties for mathematics, see (Sangwin & Jones, 2017). In particular STACK uses the computer algebra system Maxima to generate random questions; interpret students' typed algebraic expressions; establish objective mathematical properties of students' answers; and assign outcomes such as feedback and marks. Online automatic assessment has for many years been used widely in formative settings, see (Sangwin, 2013). Developing high-stakes final examinations is a natural extension of automation of formative assessment. Automation also has practical benefits, such as reducing the marking load, better test reliability, and potentially speeding up examination process. However, changing written examinations, with centuries of custom and practice, is a high-stakes and high-risk undertaking. When I examined school-level examinations (Sangwin & Kocher, 2016) the results were cautiously optimistic: a significant proportion of current questions could be automatically assessed. In this paper I extend this work and create online examination questions and trial their use with a large group of university students.

## Methodology

Changing examination processes is both high-stakes and high-risk. Furthermore, there are serious ethical problems with running an experiment in these circumstances without serious and authentic trial exams. Hence, for this study I added a mock online examination to an existing course: Introduction to Linear Algebra (ILA). This is a year 1, semester 1, mathematics course worth 20 credits taken by mathematics, computer science and other undergraduate students. Students normally take 120 credits per year, in two semesters. The course is defined by (Poole, 2011) Chapters 1 to Chapter 6.2, with a selection of the applications included and selected topics omitted. ILA had over 600 students, of whom 578 took the final written examination and had a non-zero examination mark.

Students had requested exam practice, but it was impractical to administer and mark students' attempts in the short period between the end of teaching and the scheduled examination. Students would have expected more detailed formative feedback than provided by the genuine exam, and the genuine exam takes approximately 35 person-days to mark. In context, a mock examination was likely to be taken seriously by a significant proportion of the student cohort as a valuable practice and learning opportunity. Since the mock examination did not contribute to the overall course grade there was no incentive for students to cheat, or to be impersonated. Introduction to Linear Algebra, has an “open book” examination and so possible access to materials is less of a threat to this experiment than would be the case for a closed-book examination. The lack of certainty over who was sitting the online tests, the circumstances of participation, and the potential use of internet resources is certainly a compromise. Such uncertainty does not affect the extent to which I could produce questions at a technical level, or the effectiveness of the scoring mechanism in the face of students' attempts, which themselves constitute important results and generate key points for discussion. The results consist of a report on the extent to which current questions can be faithfully automated, and I give a report on students' attempts.

## Results

The existing paper-based ILA examination takes 180 minutes and consists of Section A: compulsory questions worth 40 marks, and Section B: four questions each of 20 marks from which we take the student's best three marks. Students may use any standard scientific calculator but graphical calculators with matrix functions are not permitted.

The primary teaching goal was to provide students with an online examination which was as close as possible to the forthcoming paper-based summative course examination. The research goals were to evaluate the effectiveness of this, and to provide evidence for a discussion of equivalence with the genuine examination. ILA has been running for many years, with a stable (but not invariant) syllabus, and I had access to examinations going back to December 2011 (two per year: the main exam and an equivalent resit paper). I therefore decided to remove the oldest exam papers from easy access through the course website and base the online examination on those questions. Using as few papers as possible helps provide a representative online examination. Technically it is difficult to operate a “best 3 out of 4” mark scheme in the STACK online system and in any case for a formative mock exam this makes little sense.

In deciding how to allocate marks I have taken a very strict interpretation. Specifically, where the original intention of the examiners included “with justification”, I only awarded those marks which could be given for the answer only online. For example, Q5 on our online exam asked the following.

5. Is it possible for  $A$  and  $B$  to be  $3 \times 3$  rank 2 matrices with  $AB = 0$ ? True/False.

The original paper awarded 7 marks for the answer and justification, whereas only one mark was awarded for the correct answer. I did ask students to provide typed free-text justifications even though these would not be marked and no automatic feedback was provided. Ultimately I used two papers (120 marks each) to create the online exam. In this 59 marks of the online exam were from Dec-11 and 50 marks from Aug-12. I took one question from Dec-13 to add a mark to Section A to make the online exam total 110 marks.

Of the paper-based questions selected for the online exam, 44 marks are not awarded online. These missing marks are for justification which cannot, at this time, be automatically assessed. This resulted in Section A having fewer marks than would be the case with a paper based submission. Of the 240 marks available on the Dec-11 and Aug-12 papers, 109/240 marks 45% were automated in a way faithful to the original examinations. I think this is a remarkably high proportion, and discuss this in more detail below. However, the online versions as implemented for this study do lack some partial credit and do not (in this experiment) implement follow on-marking, which in some Section B questions is substantial. This is not a limitation of the system itself, but rather in the time available to implement more elaborate automatic marking schemes.

(d) What is the condition on the numbers  $p, q, r$  such that the plane  $px + qy + rz = 0$  contains the line  $L$  derived above? (Your answer should be an equation with variables  $p, q, r$ )

$p - 2q + r = 0$

Your last answer was interpreted as follows:

$$p - 2q + r = 0$$

The variables found in your answer were:  $[p, q, r]$

Find the equation of the plane in general form that contains the line  $L$  and contains the point  $[1, 1, 4]$ .

$3x + y - z = 0$

Your last answer was interpreted as follows:

$$3x + y - z = 0$$

The variables found in your answer were:  $[x, y, z]$

**Figure 1: Question 19d of the current study in STACK**

Note that STACK requires students to type in an algebraic expression as their answer, and an example question is shown in figure 1. For ILA, online course work quizzes were already implemented using STACK. All students were expected to sit 30 online quizzes using the STACK system as part of the ILA course before the mock examination, and would be thoroughly familiar with how to enter answers into the system. The online examination was made available to students to do in their own time for a period of one week in December 2017, between the end of formal teaching and the scheduled paper-based exam. Students could choose when to sit the online examination, but were given one attempt of 180 minutes to do so to simulate examination practice. All data was downloaded

from the online STACK system, and after ratification by the exam board, combined with overall achievement data. Students were assigned a unique number to ensure anonymity, and the data loaded into R-studio for analysis.

There were 395 attempts at the mock online exam in December 2017. One student who was granted a second attempt for technical reasons had their first attempt disregarded, giving 394 attempts. There were no other significant technical problems affecting the conduct of the online examination. For the online exam (including those who scored zero) the mean grade was 47.9% with standard deviation of 23.2%. The coefficient of internal consistency (Cronbach Alpha) for the online exam was 0.87. There was a moderate positive correlation between time taken ( $M=132$  mins,  $SD=48.6$  mins) and the online exam result ( $M=47.9\%$ ,  $SD=23.2$ )  $r(392)=0.517$ ,  $p<10^{-16}$ , as might be expected. Despite a small number of outlier questions, the mock online exam appears to have operated successfully in its own right as a test.

The final mark for ILA is made up of coursework (20%) and a final paper-based exam (80%). There were 394 attempts at the online mock examination, and all but one of these students also sat the paper-based examination. Note that 17 students scored 0 for the online exam, perhaps indicating students who looked at the online questions but made no serious attempt at them. Technically there is a difference between students who never sat the online exam, and those who opened the exam and scored 0. For the analysis I excluded the 17 students who scored 0 in the online exam: this leaves the study group of  $N=376$  students with paper and mock exam information.

For the study group, the online exam results had ( $M=50.2$ ,  $SD=21.3$ ) and paper exam ( $M=68.0$ ,  $SD=17.3$ ). For all students who sat the ILA paper exam ( $M=63.1$ ,  $SD=21.6$ ). Histograms of achievement are shown in figure 2. The “online exam” refers to scores on the online mock. The “study group paper” is the achievement of the study group on the genuine paper examination. “Paper examination” refers to the whole cohort of ILA in the genuine paper exam. There is a significantly larger failure rate (score less than 40%) in the online examination, and a significantly lower mean. These differences could be explained by the level of engagement: the online exam carried no credit, and students may have lost motivation when tired.

**Figure 2: Histograms of achievement in the online mock and paper based examinations**

A scatter plot of the online mock exam grades vs paper exam grades is shown in figure 3, together with a linear regression model. The blue dashed line shows the (ideal) linear relationship in which the online mock examination has identical outcomes with the paper-based exam. The mock exam grades and paper exam grades were moderately correlated,  $r(374)=0.593$ ,  $p<10^{-15}$ . Notice the online exam scores are clearly below those of the paper exam, supporting the hypothesis that students may have lost motivation when tired and not performed to their full potential in the online mock exam. Indeed, students scoring less than 40% in the online exam and more that 70% in the genuine exam are very likely not to have taken the online test seriously, perhaps confident (with good reason) about their ability.

**Figure 3: Online mock exam grades vs paper exam grades for the study group**

The number of non-empty free text responses to each of the “justify” questions is worthy of mention here. While no planned evaluation of the responses was part of this study, it is clear reading through the free-text responses that over 200 students took the exercise seriously, providing sensible (and often correct) justifications in good English. For the Section A questions included in this study there were 59 marks available in the paper format, whereas in the online exam only 24 marks were awarded. I did not expect students to make serious use of the free-text entry. The fact students entered sensible justification to many of these questions, and received no marks or feedback, could easily account for the difference in mean scores between the paper-based and online exam. There were a large number of empty responses (as there are on paper as well), together with some incoherent utterances, and some plaintive messages. I did not assess these free-text responses, or subject them to comprehensive analysis for the purposes of this paper. However, in a genuine online examination such responses could be assessed (1) manually in the traditional way on-screen, (2) using automatic assessment technology such as described in (Butcher & Jordan, 2010; Jordan, 2012), or (3) using comparative judgment for longer passages, see (Jones, Swan, & Pollitt, 2014; Pollitt, 2012).

## Discussion

The implementation of the mock online examination for linear algebra was a modest success. There were no serious technical problems during the conduct, and no students complained of inaccurate or

unfair marking. The results of the online examination were broadly comparable with a paper-based exam, with the consistently lower online performance explained by a combination of (1) potential disengagement in a low-stakes setting, (2) lack of assessment of students' justification (which is typically rather generous), and (3) lack of partial credit and follow through marking.

This research has done nothing to address serious practical problems associated with online examinations in general. Problems include the need for invigilation to reduce plagiarism and impersonation, and security to eliminate communication during the exam (such as answer sharing) or access to unauthorised resources. Indeed, while technology has the potential to support examination processes, there is technology specifically designed to undermine traditional examinations as well. For example the Ruby Calculator (<https://rubydevices.com.au> retrieved September 2018) is designed to aid unauthorized communication during exams. Either these examination conduct problems must be solved, or we need new models of assessing students. But these examination conduct problems have nothing to do with mathematics as a subject.

I think it is remarkable that 109/240 (45%) of the marks available on paper were automated in a way faithful to the original examinations. Further, by selecting existing questions from two existing past papers I was able to create a fully online exam, with broadly similar syllabus coverage. However, this result can be interpreted as a comment on the mechanical nature of the subject, and of the assessments we use in the traditional examination. If the assessment of students' answers can be automated, then certainly the underlying processes can be automated by the computer algebra system. Why then are students still learning to perform these mechanical processes, e.g. in the context of ILA row reduction, and calculation of determinants and eigenvalues/vectors? Both partial credit and follow through marking are technically possible in STACK, but are expensive (in staff time) to implement. To take this work further we need tools which automate assessment of explanation, justification and reasoning. In particular "proof checking" software, as applied to students' understanding, is necessary to move beyond assessing only a final answer to a full mathematical answer. In this study, only students' final answers were subject to automatic assessment which is a serious limitation to the award of partial credit and method marks. However, progress is being made to assess working especially in the area of reasoning by equivalence as discussed briefly in (Sangwin & Kocher, 2016). The work on reasoning by equivalence is essential for assessing questions in calculus and algebra, two other pillars of pure mathematics. For this reason, I am confident the cautious optimism expressed here about linear algebra exams also extends to mathematics more broadly in year 1 and 2 university methods-based examinations and mathematics examinations at the school/university interface.

I was surprised at the extent to which existing questions could be automatically assessed. However, there is nothing sacrosanct about current examination questions. Why should the online examination be exactly the same as a paper-based examination? Current questions are written explicitly for the paper-based format, and it is sensible to seek to write questions which are tuned to, or indeed take advantage of, the online format as appropriate. For many true/false questions the justification requires appropriate examples. Computer algebra is ideally suited to assessing answers, such as counter-examples, which expect the teacher to perform some time-consuming and potentially error-prone

calculation. For this research I did not rephrase such questions to “give me examples, such that ...”, but this would be one option. Specifically we could certainly have

5. Give examples  $A$  and  $B$  of non-zero  $3 \times 3$  matrices for which  $AB = 0$ .

A computer algebra system is ideally a much better tool for assessing such answers than a human marker. Hence, it would be much more sensible to design an online examination with the format in mind. Indeed, often human examiners do not ask students to “give examples of”, only because of the work entailed in marking these by hand. That said, to establish face-validity for the online examination it is useful to understand the extent to which we can assess existing questions and to establish that the technical assessment processes are equivalent.

The practical benefits of online automatic examinations include increased reliability, reduction in costs and in swifter marking times. This is very attractive to all stake holders in the process, including students, teachers and end-users of the results. It is highly likely that automatic examinations will become the norm in the near future. Online examinations will happen, but there is no need for them to be restricted to multiple choice formats. Indeed, as a community of educators we can do much better than that. However, there is a real danger that national examination boards, universities, and others with responsibilities for examinations will replicate traditional examinations online without a critical reassessment of the purpose of mathematics education.

This analysis raises the question of whether we, as a mathematics community, believe current mathematics examinations are a valid test of mathematical achievement. Do current examinations actually represent valid mathematical practice, as undertaken by researchers, industrial mathematicians and for pure recreation as an intellectual pursuit? Construct validity is a central educational concern, but it is not relevant to the research question of whether we can actually automate current exams. My personal views about the nature of mathematics broadly align with those expressed in (Polya, 1954) and (Lakatos, 1976). That is, that setting up abstract problems and solving them lies at the heart of mathematics. (Polya, 1962) identified four patterns of thought to help structure thinking about solving mathematical problems. His “Cartesian” pattern is where a problem is translated into a system of equations, and solved using algebra. Note that the algebraic manipulation is the technical middle step in the process: setting up the equations and interpreting the solutions are essential parts to complete this pattern. My previous work (Sangwin & Kocher, 2016) examined questions set in school-level examination papers and found that line-by-line algebraic reasoning, termed *reasoning by equivalence*, is the most important single form of reasoning in school mathematics. However, many examination questions do not relate to a problem at all, rather they instruct students to undertake a well-rehearsed set of techniques, isolated from any problem. Many questions in the ILA examinations also rely on predictable methods which can be well-rehearsed.

Informal discussions with colleagues, particularly during the thematic working group 21 during CERME, strongly suggest that online examinations are a concern for many working in mathematics education. The question of validity of all examinations, on paper and online, is central as is the difficult question of retaining validity if an examination format changes. Changing to online examinations provides some unique opportunities but it will be essential for stake-holders to retain confidence in any new assessment regimes, regardless of any significant merits the format brings.

Using sophisticated assessment tools such as STACK we can create a fully automatically marked examination, which is broadly equivalent to current paper-based examinations at the technical level and in terms of outcomes for students. With other tools, we can create a more rounded online examination, perhaps incorporating some human assessment of free-text justification. However, the attempt to automate assessment of students' answers reveals much about what we really ask students to do in examinations.

### **The individualization of teaching/learning at university level by means of e-learning environments**

This paper focuses on a pilot study aimed at investigating how a formative assessment (FA) frame could support the design of a sequence of tasks to foster individualized teaching at university level. Many obstacles are encountered by teachers and students at university level: the large number of students per teacher, the heterogeneity of students' background, the small number of hours per course, the impossibility of creating a close and frequent relationship between lecturer and students (De Guzman, Hodgson & Villani, 1998). In relation to this, Nardi (2017) stresses that there is an “aspiration (institutional but not only) for a more approachable, more inclusive and more engaging learning experience in university mathematics that is tailored to individual student needs” (p.10) and suggests that e-learning could give a significant answer to this aspiration.

In the past few years, research highlighted the effectiveness of designing e-learning environments to support the teaching-learning processes at tertiary level (Descamps et al. 2006; Albano & Ferrari 2008; Albano 2011; Bardelle & Di Martino 2012; Calvani 2005). In fact, these environments allow teachers to keep trace of students' work and mistakes, to provide an automatic or semi-automatic evaluation and to share feedback and comments. Moreover, they enable students to overcome the fear of being judged and of revealing lack of knowledge by requesting clarifications. In this way gaps in students' knowledge can be reduced, even within the heterogeneity of large classes.

These last observations make us concentrate our attention on the crucial role that e-learning could play in fostering individualized and personalized teaching at university level (Bardelle & Di Martino 2012; Albano & Ferrari 2008; Albano 2011). Bardelle and Di Martino (2012) stress that an e-learning environment could be an effective context through which it is possible to counteract students' mathematical difficulties in the tertiary transition, since it enables to foster both the personalization of the learning path and the students' collaboration during the activity. Also, Albano and Ferrari (2008) discuss the strong impact that these online environments could have at all levels

of learning (cognitive, metacognitive and affective), allowing the automatic individualization of learning path according to the student's profile.

### **Theoretical framework: FA as a tool to support individualized teaching/learning**

In this study, we refer to the distinction between individualization and personalization proposed by Baldacci (2006). According to Baldacci, *individualizing* means differentiating the didactical paths in order to enable all the students to reach common objectives, while *personalizing* is differentiating the formative goals and objectives to promote individual potentialities.

In our research we focus on the individualization of teaching/learning paths because, in our opinion, the specific characteristics of university teaching, such as the large number of students per teacher and the impossibility of differentiating formative goals (since all students need to reach minimum levels to attend subsequent courses), prevent from realizing a complete personalization. Moreover, we think that individualization could represent a useful approach to support students in the gaps of knowledge due to the heterogeneity of their background.

Jenkins (2004) suggests to looking at web technologies to promote the use of different assessment methods, especially in the context of higher education, stressing that this kind of technologies can encourage collaborative and reflective styles of learning and can also become adaptive. In tune with these ideas, we decided to set the design of a sequence of tasks for university students within a FA framework, where FA strategies are conceived as critical tools to foster the individualization of teaching/learning.

We refer to the model for the use of technology to support FA developed within the European project FaSMEd (Cusi, Morselli & Sabena, 2017). The model extends the one introduced by Wiliam and Thompson (2007), which considers two main dimensions. These are the agents involved in FA processes (the teacher, the learner, the peers) and the key strategies for FA: (a) clarifying and sharing learning intentions and criteria for success; (b) engineering effective classroom discussions and other learning tasks that elicit evidence of students' understanding; (c) providing feedback that moves learners forward; (d) activating students as instructional resources for one another; (e) activating students as the owners of their own learning. According to Wiliam and Thompson, FA should be designed with the aim of enabling the teacher and the students to establish: *where the learners are in their learning; where they are going; what needs to be done to get them there*. Within FaSMEd, a third dimension has been added, that is the functionalities of technology that could support FA: sending and displaying; processing and analyzing; providing an interactive environment.

Another important element for our framework is the role played by feedback in FA. Nicol and Macfarlane-Dick (2006) define feedback as an “information about how the student's present state (of learning and performance) relates to goals and standards” (p.2). The authors propose a model that distinguishes between *internal feedback*, generated by students' monitoring of their interactions with the task and the internal and external outcomes of their work, and *external feedback*, provided by the teacher, by a peer or by other means; external feedback must be interpreted, constructed and internalized by students to have a significant influence on subsequent learning. We refer also to

Hattie and Timperley's (2007) distinction between different levels of feedback. In particular, we focus on feedback about (i) the task; (ii) the processing of the task; (iii) self-regulation.

### The tree of tasks: the design of individualized teaching/learning paths

In this section, we present a sequence of online tasks that is conceived as an intertwined collection of individualized teaching/learning paths. The tasks are organized in a tree (the tree of tasks, TT) and dynamically connected, so that the learners could face them within intertwined different paths, depending on the answers they give and the difficulties they encounter. The TT has been designed with the aim of supporting undergraduate students in the learning of basic topics of elementary and conditional probability. It is constituted by five main tasks, implemented with Geogebra and submitted to the students by using the university Moodle platform.

The diagram in figure 1 summarises the structure of the TT. All the possible intertwined paths begin with the same task (E1), concerning the definition of conditional probability, the probability of the intersection and of the complementary events. For all the tasks, students are required to give open (numerical) or multiple-choice answers to some questions and can choose to ask for specific hints. An immediate *feedback about the task* is provided whenever a student gives an answer and an overall feedback (again *about the task*) is given both at the end of the task and the whole path. The functionalities of technology that are activated to carry out this online self-assessment are *processing and analyzing* and *providing an interactive environment*.

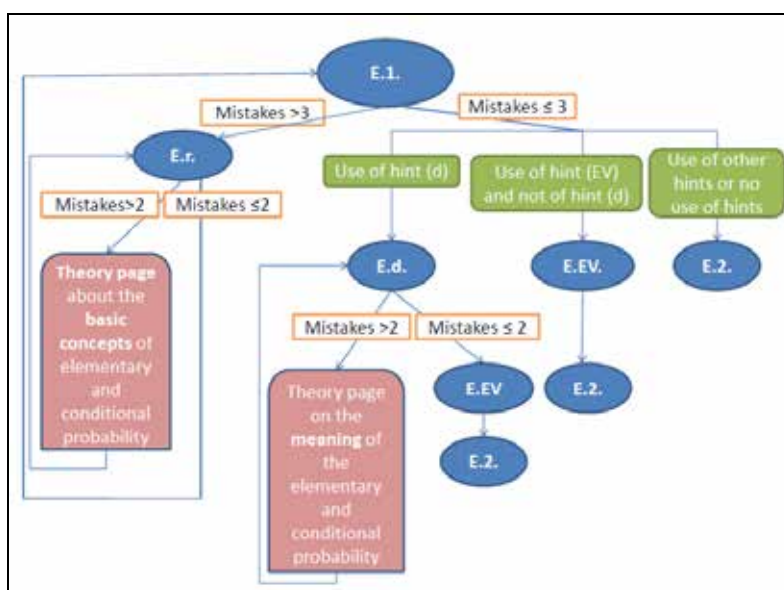

Figure 1: The tree of tasks

According to the number of mistakes and the kind of hints the students ask for, they are directed to different tasks. For example, if students make more than three mistakes in E1, they are directed to the task Er. After this, if they make more than two mistakes, they are directed to a theory page and then again to Er, otherwise they are directed to E1.

Because of space limitations, here we present only task E1 and the corresponding feedback and hints. Within this task, a brief text in natural language, introducing some events and their probabilities (their values are random), appears on the screen (see fig. 2). The student is required to

fill six input fields by inserting the probability of various events: the probability of A and its complementary, the probability of the intersection  $A \cap B$  and the probability of the conditional events  $B|A$ ,  $\bar{B}|\bar{A}$  and  $\bar{B}|A$ . Three of the required values are given in the text, so that the students should carefully interpret it; the other three input fields can be filled by using the definition of conditional probability, the property that a conditional probability is a real probability with respect to the conditioned event and the generalized rule for the probability of the intersection event. If all the six fields are correctly filled, two other questions, about the independency and the incompatibility of the events A and B, appear on the screen (see fig. 2).

When facing task E1, the students can ask for five different hints (see fig. 2): a summary of the data given within the text, represented through symbolic expressions (d), the Euler-Venn diagrams of the events (EV), a calculating machine (c), a sheet and a pen (sp) and a list of useful formulae (f).

As summarised earlier, if a student makes more than three mistakes, he/she is directed to a reinforcement task (Er), which is focused on the probability of the complementary of an event and on the definition of conditional probability. If not, the next task depends on the specific hints that are required: if a student asks for the hint d, he/she is directed to a specific task about the understanding of the given elements in a text expressed in verbal language (task Ed); if he/she does not ask for the hint d, but he/she asks for the hint EV, he/she is directed to a specific activity about the meaning of events in terms of set operations (task EEV); if the student does not ask nor for hint d, neither for hint EV, he/she is directed to task E2.

**Calculate the following events' probabilities, by assuming that**

The event A happens with probability  $\frac{1}{5}$ . If A has happened, B verifies with probability  $\frac{7}{8}$ . By knowing that A did not happen, B does not verify with probability  $\frac{3}{4}$ .

$P(A)$   **Right!**       $P(A \cap B)$   **Be careful!**  
 $P(\bar{A})$   **Be careful!  $\bar{A}$  is the complementary event of A!**       $P(B|A)$   **Right!**  
 $P(B|A)$   **Right!**       $P(\bar{B}|\bar{A})$   **Be careful!  $B|A$  is NOT the complementary event of  $B|A$ !**

**Answer the following questions (1=yes, 0=no)**

Are the events A and B independent?  **Right!**

Are the events A and B incompatible?  **Be careful! A and B are incompatible if  $A \cap B = \emptyset$**

**let's go to the reinforcement activity**

**If you need, you can choose one or more hints to perform the task.**

- ☒ write the problem data
- ☐ give me the Euler-Venn diagrams of the events
- ☐ give me a calculator
- ☐ give me a sheet and a pen
- ☐ give me the formulae

$P(A) = \frac{1}{5}, P(B|A) = \frac{7}{8}, P(\bar{B}|\bar{A}) = \frac{3}{4}$

Figure 2: A screenshot from task E1

All the tasks are designed by taking into account misconceptions and typical mistakes that affect the teaching/learning of elementary and conditional probabilities (Diaz & de la Fuente, 2002). Moreover, as the above description highlights, the TT is engineered in order to gather information not only about students' mistakes, but also about their preferred approaches, displayed thanks to the hints they ask for. Students' behaviour and choices within the interactive environment determine the sequence of tasks proposed to them, that is the *individualized path* within which each of them is involved. We can speak about individualized paths because students are stimulated through various learning channels (graphical, symbolic, verbal ...), they are given the possibility to follow their own

aptitude and skills, and, finally, they can access to online resources when they prefer, so their learning rhythms are respected.

As for FA processes, it is possible to highlight a continuous activation of FA strategy C (*providing feedback that moves learners forward*), through both the direct *external feedback about the task* given to students, and the *indirect external feedback* that they receive when they are directed to specific tasks. This kind of feedback is on the *processing of the task* and on *self-regulation*, because it is aimed at making students reflect on specific aspects of their knowledge, on their own difficulties and on the role that each hint could play.

In order to collect evidence about students' typical approaches and mistakes, we have designed an open-ended questionnaire, composed of sets of questions to which the students have to answer after the completion of each task (8 questions for each task) and at the end of the learning path (3 questions). Some of the 8 questions focused on the specific mathematical contents to which each task refers and require students to write argumentations *about the processing of the tasks* they faced. The remaining questions focus on metacognitive aspects, such as the difficulties met by students in facing each task, the role of the hints they required, the ways in which each task could support their learning.

The request for argumentation is aimed, on the one hand, to assess students' capability of justifying their own strategies, and, on the other, together with the request for specific reflections, to guide them in monitoring their interactions with the tasks and in making explicit their interpretation of the received *external feedback*. In this way, students could gradually become aware of the possible strategies to face the task and on the reasons behind them, generating their own *internal feedback*. Two other FA strategies are therefore activated through the TT: strategy B (*engineering learning tasks that elicit evidence of students' understanding*) and strategy E (*activating students as the owners of their own learning*).

## Research focus and methodology

In this paper, we aim to highlight the effects of students' interaction with the activities we designed to foster individualized learning paths, in terms of: (1) students' development of awareness about their own learning progresses and needs (that is, their awareness about "*where they are*" in their learning and "*where they are going*"); (2) students' declared perception of the impact of the implemented online tasks on their learning (that is their ideas about the role that the tasks could play in making them aware of "*what needs to be done*" to reach the learning objectives).

The activity presented in the previous paragraph was proposed to a group of 15 engineering Master degree students. In this paper we focus on their answers to the following metacognitive questions, which are part of the open-ended questionnaire introduced in the previous paragraph: (1) Did you meet some difficulties in facing the task? (2) Did you use the hints? If yes, what hints did you use? (3) Were the hints useful? (4) Would you have preferred to use additional or different hints? (5) Did the task help you clarify the concepts used from elementary and conditional probability? These questions are aimed at highlighting the *internal feedback* generated by the students' monitoring of their interaction with each task.

We developed a qualitative analysis of the students' answers to the metacognitive questions, referring to our research foci. The analysis of questions 1-2-3-4 was aimed at detecting evidences of students' awareness about: (a) their difficulties in facing the tasks (possibly connected to their general difficulties in mathematics), (b) the gaps in their learning and (c) the role played by the hints they chose (research focus 1). In particular, we looked for possible categories of students answers in relation to their level of awareness about these aspects (a, b, c).

The analysis of question 5 was aimed at investigating students' perception of the impact of the tasks on their learning (research focus 2). In particular, we focused on the identification of the ways in which the students interpret the hints and the external feedback provided by the TT as supports for their learning.

Each researcher coded the students' answers separately in relation to our research objectives. Afterwards, problematic codes were discussed together so that researchers came to an agreement.

### **Analysis of students' answers**

Referring to the *research focus 1*, we can identify at least three different categories of answers, depending on students' level of awareness about their own learning progresses and needs. The answers belonging to the *first category* show that students are deeply aware of the difficulties they faced in the resolution process, able to explain the reasons behind them and to put them in relation with their typical difficulties with the mathematical topic. Often, this kind of answers is associated to students' capability of recognizing their needs and asking for the suitable hints, when it is necessary. An example is S1 answer to question 1 after the completion of task E1: *"I did not meet many difficulties in facing this task, but it took me some time to understand what kind of probability was given in the text of the problem. Since it is a kind of difficulty that I often have, especially in understanding the distinction between conditional probability and the probability of the intersection of events, I tried to be particularly careful"*. This answer represents an evidence of S1's capability of connecting the specific task to her general difficulties (in understanding verbal texts), and of reconstructing both the learning path and the reflections made in facing the activity.

The *second category* of answers is characterized by the fact that students are only partially aware of their difficulties and show an inadequate control of the strategies to be activated to overcome them. An example of answer belonging to this category is the one of S2, who writes that his failure in facing task E1 is due to the fact that he was not able to *"remember the formula for  $P(\bar{B}|\bar{A})$  and  $P(\bar{B}|A)$ "*, but he asks for hint d (the representation of data through symbolic expressions), which is not useful for him, and answers to question 4 only stating *"I don't know"*.

The answers belonging to the *third category* are those that are given by the students who do not recognize their difficulties at all or recognize some difficulties but do not activate adequate strategies to overcome them. The typical approach of these students is, for example, the one of S3, who declares that his usual difficulties are related to the understanding of the data within the verbal text of the problem, but answers to question 2 (after task E1) stating *"I have not considered the hints at all"*. The choice of not asking for hints clashes also with the fact that he completed task E1 making more than 3 mistakes.

As regards *research focus 2*, our analysis of question 5 highlighted the students' general appreciation of the TT. The most frequent reasons of this appreciation are connected to the fact that an interaction with a non-human tutor enables students to avoid their fear of being judged, as S4 stresses in his answer: *"Working alone on these online activities was great: not having the pressure of the teacher or a classmate who looks at my work and judges it allowed me to reason calmly, without the fear of making mistakes. It was like being a trapeze artist with the safety net"*.

Most of the students seem to not fully understand the advantages of the individualized learning path in which they were involved, but they recognize the TT as a learning resource useful to explore multiple representations and promote transformations between them. The direct *external feedback* given by the software is interpreted as useful support to students' learning. For example, S5, referring to task E1, writes: *"I used the rules to determine the probability of the complementary event and the message that appeared when I inserted the value of  $P(\bar{B}|\bar{A})$  reminded me that  $\bar{B}|\bar{A}$  is not the complementary of  $B|A$ "*. Another aspect that is particularly valued by students is the usefulness of the hints. Some students stress the role played by the hint EV (Euler-Venn diagrams) in reinforcing the meaning of the compound events by the graphical representation of events as sets.

Finally, it is interesting to observe that none of the students refers to the aim of passing the examination. They in general consider the TT as a good self-assessment tool and as a way to point out some critical aspects in the theory of elementary and conditional probability. For example, S6 declares: *"Yes, I found this task (E1) useful because it is focused on the difference between incompatibility and independence of events. The task has enabled me to clarify that I can consider  $P(A \cap B)$  to investigate both the concepts, but I have to use it in different ways..."*.

## Final remarks

In this paper we presented preliminary results from a pilot study developed to investigate university students' perceptions of the impact of individualized online teaching/learning paths designed within a FA frame. In particular, the analysis enabled us to highlight students' elaboration of the external feedback received during their work on the TT, in terms of information about where students are in their learning and what they need to do to reach the learning objectives. The students participating to the pilot study showed different levels of awareness about these aspects: few of them were both aware of their difficulties and capable of activating the necessary strategies to overcome them. A common trend is that students recognize the value of the TT as an effective environment to support their learning, but they do not completely realize the level of individualization provided by the TT. For this reason, we will test a redesign of the methodology of use of TT, characterized by the fact that the individualized activity with the TT will be followed by a collective meta-level discussion during which the university teacher and the students will compare the individual interactions with the online tasks and will reflect on their usefulness.

Most of the students show that they are not used to carry out the kind of reflections that the questionnaire forced them to develop. This suggests the need of re-designing the questionnaire as an integrated part of the TT and as a tool to support self-assessment.

As a future development of this research, we will explore the use of this approach with reference to other knowledge domains of mathematics. Moreover, we will focus on the teachers' perspective,

investigating the ways in which the information gathered through this online environment (the track of students' interaction with TT, the hints they ask, the argumentations and reflections they produce...) could represent a useful feedback for university teachers in revealing cognitive and metacognitive difficulties of students and in suggesting suitable re-design of the tasks to better support students in overcoming these difficulties.

*This report deals with the design of a teaching and learning pathway that encompasses an assessment method coherent with the educational long term goal chosen by the teacher. More specifically, it is aimed at contributing to promote high school learners' culture of theorems – i.e. mastery of conjecturing and proving supported by meta-mathematical knowledge. The assessment method, which combines formative assessment all during the teaching sequence and final assessment based on student's self-reflective report on her learning trajectory, has been implemented in 10th grade classes. A written essay, in form of letter written by the students to a fictitious schoolmate at the end of the pathway, is analysed in order to evaluate the potential of the implemented course.*

*Keywords: Formative and summative assessment, proving, secondary school.*

### **Introduction**

In this contribution, we address the following issue, as outlined in the call for papers of TWG21: “The assessment of specific mathematics domains – such as for example algebra or geometry - or capabilities such as problem solving or mathematical modelling”. More specifically, we refer to the teaching and learning of mathematical proof and proving, conceptualized as the development of a specific “culture of theorems” (Boero, 2007). In our research group, we have been working for many years in the development of specific constructs and related experimental activities concerning proof and proving. In particular, we designed methods to foster students' awareness of crucial aspects of proving concerning their inherent strategies, what warrants the truth of the statements, and the logic-linguistic features of proof (Boero, Douek, Morselli & Pedemonte, 2010). Here we focus on the design of a whole teaching and learning pathway that encompasses also formative assessment strategies and final assessment of the individual competencies. From one side, we believe in the efficacy of formative assessment strategies in promoting the development of a culture of theorems. From the other side, we recognize that promoting a culture of theorems, in order to be effective in the institution, requires a coherent method of final assessment. For this reason, we inserted an innovative method of summative assessment in the project. The aim of this report is to present the teaching-learning (and assessing) pathway as it was implemented in two 10th-grade classes, and to illustrate data that provide some initial evidence of its effectiveness.

### **The culture of theorems**

We refer to Mariotti (2001)'s construct of theorem: the theorem is made up of the statement, together with its proof within a theory. For the same statement, it is possible to consider different ways of proving it, according to different methods of proof and different theories. In that perspective,

competencies in conjecturing and proving concern, in particular, the mastery of meta-mathematical knowledge regarding: the shape of statements (hypothesis, thesis); different methods to validate a statement; the distinct role of previously proved theorems (as synthesizers of deductive chains needed to build up the proof) and axioms (as founding stones of a theory); the distinction between the construction and plausibility of a conjecture (based on different processes: induction, abduction, analogy, etc.) and the construction of a proof (which aims at a deductive enchainment of propositions within a theory). The development of a culture of theorems requires: autonomy in acting as problem solvers in conjecturing and proving; awareness of meta-mathematical issues (like the epistemic constraints and logic-linguistic features of proof – Stylianides & Ball, 2008), which play a crucial role both in understanding a proof produced by others, and in conjecturing and proving by themselves. Promoting a culture of theorems in classroom means to foster students' awareness of these aspects and to make students develop a meta-mathematical knowledge (Boero et al, 2010) that supports the self-regulation of the process of conjecturing and proving.

### **The crucial role of assessment**

We believe that assessment must be consistent with teaching's aims and with task design. As a starting point, we refer to the known distinction between formative assessment and summative assessment. Summative assessment occurs at the end of the learning activity with the goal of estimating the individual student's achievement (McIntosh, 1997), and is generally used as part of the grading process. Formative assessment is performed during the learning activity with the aim of improving learning. It is also called "assessment for learning" and may be considered a method of teaching where "evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction." (Black & Wiliam, 2009, p.7). Wiliam and Thompson (2007) describe five key strategies to promote formative assessment in classroom, involving three agents: the teacher, the students and the peers. The five strategies are: a) clarifying and sharing learning intentions and criteria for success; b) engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; c) providing feedback that moves learners forward; d) activating students as instructional resources for one another; e) activating students as the owners of their own learning. Moreover, Nicol and Macfarlane-Dick (2006) argue that formative assessment may promote students' self regulated learning. Recognizing formative assessment as crucial for learning does not mean to deny the crucial role of summative assessment. At the same time, it is important to move beyond a summative assessment that confines itself to a mere "final test", that hardly provides reliable information on the competencies that are acquired. For instance, Taras (2001) describes a research where cycles of summative self-assessment, tutor feedback on self-assessment and final revised self-assessment are carried out. The issue of summative assessment in mathematics becomes crucial when it has to be set up after innovation teaching and learning sequences. Assessment methods based on individual problem solving and answering teacher's questions usually have a negative impact on the development of students' autonomy and responsibility as learners in the classroom social context. In the special case of the teaching and learning of proof, traditional individual assessment tasks (presenting learnt proofs, adapting learnt proofs to similar situations, only seldom producing and validating conjectures), result in students' focusing on the products and their features.

## **Assessment in a “culture of theorems” perspective**

In our teaching and learning pathway, we aimed at creating a formative and summative assessment that is coherent with the whole educational plan, aimed at promoting a culture of theorems. In the culture of theorems, it is important to make students active and autonomous, willing to take the responsibility of creating their own proofs and critically analyse the proofs produced by others. Accordingly, we created activities where students give constructive feedback to their mates and take profit from mate's feedback, becoming at the same responsible of their own learning and resources for the mates; in this way, formative strategies d) and e) (Wiliam & Thompson, 2007) are promoted. The formative assessment activities are integrated with a summative assessment method based on the student's self-reflective report on the personal learning trajectory, so as to assess whether the student is able to exploit the previous formative assessment activities and act as an autonomous learner. We hypothesize that thanks to the sequence of activities students not only are more free to take intellectual risks in conjecturing and proving, but may be induced to use meta-mathematical aspects of conjecturing and proving as key tools to regulate their productive and reflective activities – given their role (supported by the teacher) in analysing their fellows and their own conjecturing and proving performances. We also hypothesize that a final assessment method, based on their self-reflective reports on their learning trajectory, might offer them the opportunity to get acceptable results and at the same time would offer them (also thanks to the kind of work performed in the classroom) key tools to re-orient and improve their work. Such an assessment method might also be useful for another reason, related to the condition of so many students who enter high school in our country (and in others too) with low self-confidence and scarce willingness to take intellectual risks. Failures in traditional assessment tasks would confirm them in their disposition towards classroom work (Boaler & Greeno, 2000). We note here that such a form of summative assessment may be considered as an integral part of the teaching and learning pathway and, then, the boundary between formative and summative assessment is not strict in the project. A more detailed description of the teaching and learning method, as well as of the assessment strategies, is provided in the subsequent paragraph.

## **An innovative teaching and learning (and assessing) project**

### **The context**

Our teaching method and assessment choices was implemented in one 10th-grade class of 21 students in the year 2016/17 and in two 10th-grade parallel classes (of 31 and 19 students) in 2017-18. The classes belong to the scientific-oriented high school, which in our country prepares students for all academic courses, especially for the studies in STEM. We focused on the geometry course, that is taught 2 hours each week, from October to May, in parallel with 3 hours devoted to algebra (first and second degree equations and systems of equations, functions, etc.) and probability, taught by the same teacher. The course consists of 3 modules of about 16 hours each; it concerns some content of Euclidean plane geometry, typically taught in our country in the first two years of high school: (first module) to construct a tangent circle to two intersecting straight lines; to construct the tangent circle inside a given triangle; (second module) to study different cases of triangles inscribed in a circle (rectangle, isosceles, equilateral triangles), with related necessary and sufficient conditions; to study the relations between peripheral angle and central angle; (third module) given a circle, to study the

relationships between its tangent and intersecting straight lines; and, given a circle, to deal with some problems concerning inscribed and circumscribed quadrilaterals. The geometry course in grade 10 follows a grade 9 course in Euclidean plane geometry of triangles and quadrilaterals, which, in our case, was taught by the same teacher. All the lessons were given by the teacher (author FT); one researcher (the author PB) was present and acted as participant observer.

### **The course: teaching and formative assessment**

In our pathway, a sequence of classroom activities (“module”) usually consists of some cycles, each of them starting with an individual work on a worksheet, which includes one task and some information and framing of it. The task is open, possibly with some general suggestions about how to deal with it; it involves one of the following activities: conjecturing, with the aim of getting a statement conforming to the requirement of Euclidean geometry; constructing a geometric figure (which corresponds to the “building-up” part of Euclid’s constructions); proving of produced conjectures, or justifying produced constructions (after they have been shared and better formulated under the guide of the teacher in classroom discussions); analysing mates’ productions of previous tasks; identifying salient meta-mathematical aspects of produced texts. We note again that peer review is an efficient way of carrying out formative strategies d) and e) (Wiliam & Thompson, 2007). Each initial individual task of the cycle may be followed by an individual (or small group) analysis of some representative students’ solutions to the task, chosen by the teacher; and/or by a direct classroom discussion of those solutions, guided by the teacher. In this way, formative assessment strategies b), d) and e) are activated (Wiliam & Thompson, 2007). Discussion is addressed to identify gaps, mistakes, points of strength, differences of produced strategies, linguistic issues and meta-mathematical aspects. Students are particularly motivated to engage in these activities, because they will turn to be useful for the the preparation of the final personal report (the key material for their summative assessment- see below). Usually, the second phase of the cycle ends with a synthesis, guided by the teacher, about one (or some) different ways of solving the problem – special care being devoted to the organization of the proof text (in the case of tasks asking for a proof of a given statement) according to meta-mathematical constraints. The synthesis is a key moment for clarifying and sharing learning intentions and criteria for success (strategy a), Wiliam and Thompson, 2007). For some crucial steps of the sequence, students are then requested to write the refined, shared solution for the same task; or to identify hypothesis, thesis, theorems or axioms used as warrants, etc. in a proof text written by the teacher. Table 1 summarizes the activities that were carried out, in reference to the activated formative assessment strategies (as described by Wiliam & Thompson, 2007).

<b>Activity</b>	<b>Formative assessment strategy</b>
Class discussion on selected productions	b) engineering effective classroom discussions that elicit evidence of student understanding; c) providing feedback that moves learners forward; d) activating students as instructional resources for one another; e) activating students as the owners of their own learning
Peer review of selected productions	d) activating students as instructional resources for one another; e) activating students as the owners of their own learning

Class discussion to synthesize and organize the final product, with a focus on meta-mathematical aspects	a) clarifying and sharing learning intentions and criteria for success; b) engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding
----------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Table 1: Activities and related formative assessment strategies****The final assessment**

Final assessment is made up of two parts: part A is performed at home, part B is done in classroom. In part A students are requested to prepare (at the end of each of the three modules of the geometry course) a written revision of each of the worksheets produced during the module, followed by a synthesis paper. Students' revision work of personal filled worksheets concerns: identification of gaps, mistakes, difficulties and lacking knowledge at the content and at the meta-level; remediating gaps and mistakes, but in strict agreement (when appropriate) with the personal line of thought. According to our hypothesis, students are engaged in using criteria of meta-mathematical type to identify their difficulties and mistakes, with an inner questioning: "Does my conjecture contain a hypothesis and a thesis? (...) Are there some gaps in my enchaining of propositions?". This questioning at the intra-personal level would echo what should have happened at the inter-personal level in the classroom interactions managed by the teacher, and would contribute to enter the culture of theorems. The synthesis paper concerns: difficulties met during the module, and when and how (and if) they have been overcome; and on relevant learning progresses, and how they occurred, taking the collective classroom work into account. In part B, performed in classroom, students are asked to do the written revision of three worksheets, chosen by the teacher (one of them produced by a schoolfellow, the others by the student herself – thus, a second revision for them). Its purpose is to avoid that the student merely relies on help provided by some more competent fellow (or another expert person). There is no other assessment task for the geometry course. The final grade is given to each student taking into account the involvement during all the pathway (participation to the individual and groupwork and to the discussions) and the final assessment (parts A and B). Criteria for assessing parts A and B concern students' ability in: revising mistakes; improving written productions in terms of completeness, correctness and clarity; reflecting on the personal learning pathway. Essential features of the *assessing method* are similar to those implemented at the university level as described in (Guala & Boero, 2017).

**Evaluation of the project: preliminary results**

Our evaluation of the educational project is aimed at understanding whether the pathway was efficient in promoting students' culture of theorems, with specific reference to autonomy and awareness of meta-mathematical issues. For the evaluation, as we'll detail hereunder, we rely on direct observation of the students' activities and fieldnotes, as well as on the qualitative analysis of a special reflective task that was carried out by the students at the end of the pathway.

From the direct observation of students' activities and the fieldnotes of the teacher and the observer, we got some preliminary evidences of the fruitfulness of the adopted method. First, students' relationships with their mistakes and pitfalls during the individual work on their worksheets gradually

evolved (at the beginning, mistakes and wrong paths to the solution were carefully erased or whitened in order to hide them; gradually students realized that the memory of wrong paths and mistakes is useful to prepare their self-reflective report, but also to better take part in discussions). Second, there was a growth in the attention paid by students to meta-mathematical aspects: gradually, more and more teacher's (or peers') comments on those aspects are reported in students' notebooks. Third, there was an evolution on kind of students' requests and comments concerning meta-mathematical aspects addressed to the teacher (or their schoolfellows) during classroom discussions.

At the end of the three modules, the students were proposed a reflective task: they were asked to write a letter to a fictitious schoolmate, describing the way of working with theorems they lived during the year. The idea of asking students to narrate their experience to a fictitious schoolmate is coherent with the learning-teaching pathway, where students were encouraged to act as resources for the peers; moreover, the request to write a letter was aimed to promote an informal style, where each student could feel free to insert personal reflections on the pathway. Here is the text of the task:

Paolo, a student of your age, will move to our school and will attend the second year course. By now, he did not do any specific activity on theorems (maybe he has some idea of what is a theorem). Since he heard that your class worked a lot on the statement and the proof of theorems, he would like to contact you to get a clearer idea on the theme. Write a letter to Paolo, telling briefly your experience; explain in particular what is the statement of a theorem and what does "proving it" mean.

We analysed the written letters, looking for elements of meta-mathematical knowledge, as well as reflections on the way students lived the pathway. We realized a qualitative analysis of the texts (performed by the authors separately and after compared and discussed so as to reach an agreement), that we summarize in the subsequent part of the paragraph. Concerning mathematical and metamathematical knowledge related to theorems, most students are able to discuss the key features of a theorem. They point out relevant elements of the statement (hypothesis, thesis) and are able to discuss the issue of validity of the theorem.

Ema: the statement is made of two parts: hypothesis and thesis. The hypothesis is often introduced by "IF", and it is the sentence that you suppose to be true or it is necessary to start your proof. The thesis is often introduced by "THEN" and it is that sentence that you proved in your proof and that, thanks to your proof, is true.

Giu: In mathematics, the THEOREM is a statement that, starting from initial assumptions that are taken as true, draws some conclusions, by means of a precise proof. Proving a theorem means to affirm its validity, following precise properties or mathematical laws.

We note that students are also able to describe proving as a process aimed at producing a final product, which is a relevant metamathematical issue.

Lor: there are different ways to think of a proof, I'll propose you some of them. The most common is to see a theorem as a mathematical problem; in both cases [the theorem and the problem] there are starting points and final points, justified by calculations or known theorems, that is to say already proven. But the interpretation [of theorem] I like the most is another one: you must imagine

the theorem as a travel. [...] Before starting the travel, but also during the travel, you must keep in mind the final destination (the thesis) and avoid roads that may lead you to a wrong reasoning. Like in a travel, there can be different roads that lead to the same destination, the thesis.

Giu: a good proof must be organized into three parts: exploration, with the construction of the figure, and observation of all possible relations between the parts of the figure; search for relations that are useful for the proof, with the support of mathematical laws and theorems that allow to affirm that a given thing is true; synthesis of all the process with letters, so that it is precise, well formulated and synthetized.

The letters contain also many hints on efficient ways to perform the process. This is again an evidence of awareness of metamathematical issues; moreover, the fact of being able to describe the process and “give advices” to the fictitious mate reveals that the students became responsible of their own learning, real protagonists of the pathway, and also ready to act as resources for the mates.

Giu: In general, during the proof you must observe the figure with careful and “wise” eyes, so as to reach a conclusion. [...] I suggest you to pay attention to the text of the task and to the figure, to write down all your observations and, even if you think they are un-correct, because they will become useful for the subsequent auto-correction activity. I suggest you to carry out the activities with a lot of care, for me it was very useful.

Mar: I suggest you not to focus on a single aspect of the statement, but to have a wider view and try to think of known theorems that could be useful.

The letters contain a description of the learning pathway, often intertwined with personal reflections on the way the students lived such an experience.

Marco: I liked very much this pathway, because it made me appreciate more geometry, that I did not like very much until last year. This system of activities (proving, constructing, experimenting) made some arguments nicer and helped me to learn them in a better way.

Ser: before starting the pathway I felt unsecure and skeptical, but I changed my opinion. I started the pathway with a little knowledge (few theorems and laws), that I had to review and re-discuss. During the pathway I thought again to that period of time when children ask the reason for everything, because by means of the activities we questioned many things that we had always taken for granted. [...] You can’t imagine how many times I struggled with wrong ideas that did not lead me anywhere, or we had an idea that we could not develop.

Some students even reveal a good awareness of the rationale of the educational pathway they experienced.

Giu: for me, the activity of correcting our mates’ answers was very useful, because we had to understand his reasoning and possibly correct some imperfections.

Mat: do not worry if at the beginning you can’t find the good proof or fill the worksheets, because this is a new method for you, as it was for us. Indeed, the teachers do not judge the mistakes but evaluate your ability to recognize and correct mistakes by yourself. Moreover, this pathway will help you to get into another mate’s reasoning and complete or correct it.

## Discussion and further developments

The preliminary analysis of the letters provided some evidence for the effectiveness of our pathway, with particular reference to the students' development of meta-mathematical knowledge concerning the culture of theorems and growing assumption of responsibility as learners. The research is still ongoing and we are currently analysing the reflective reports provided by the students at the end of the three modules. Some issues need further reflection. One crucial issue is: how to grade self-reflective reports in an objective way? Sharing with students precise criteria might better orient their work and make more explicit the teacher's expectations, but it could lead students to conform their reflections to a model. Another aspect which needs careful consideration is the development of students' awareness about their growing up as learners in the classroom context. It was put into evidence in a few final letters, while it is relevant for the development of competencies.

*This paper explores the relationship between characteristics, beliefs, backgrounds and perceptions of students and instructors with students' grade earned in algebra courses at two-year post-secondary institutions in the U.S. using multiple linear regression. We present the results of an analysis of data collected during the Fall 2017 semester. From this analysis we seek to highlight a few predictor variables with significant influence on the outcome variable of student grade in the course and provide interpretations of these results.*

*Keywords: Algebra, grade prediction, post-secondary institutions, multiple regression analysis.*

Community colleges in the US enroll 43% of all undergraduate students enrolled in two-year post-secondary institutions (Blair, Kirkman, & Maxwell, 2018). These institutions offer students the opportunity for remediation, transfer to four-year undergraduate institutions, vocational training, general education, continuing education, and worker retraining (Mesa, 2017) thus providing students of all income levels access to higher education at a minimal cost. As a result of the open access policies of community colleges, students bring a variety of backgrounds in terms of age, educational attainment, and family/work/socioeconomic status to math classrooms. To meet the needs of these students, the mathematics courses taught at a typical community college range from developmental courses (review of arithmetic and algebra courses) through courses offered during the first two years of an undergraduate mathematics major. Bahr (2010) noted the algebra courses at these colleges have failure rates ranging from 30% to 70%. Thus, there is a need to better understand factors that affect student success in these courses. Towards this end we investigate the relationship between the characteristics of instructors teaching these courses and their students' percent grade.

Sadler and Sonner (2018) found that high school students who master coursework preparatory to calculus, including algebra, geometry and precalculus, perform well in college calculus courses.

---

<sup>1</sup> The AI@CC Research group includes: Megan Breit-Goodwin, Anoka-Ramsey Community College; Anne Cawley, California State University, Pomona; April Ström, Chandler-Gilbert Community College; Randy Nichols, Delta College; Anna Bright, Patrick Kimani, Fern Van Vliet, and Laura Watkins, Glendale Community College; Angeliki Mali, Groningen University; David Tannor, Indiana Wesleyan University; Jon Oaks, Macomb Community College; Nicole Lang, North Hennepin Community College; Carla Stroud, and Judy Sutor, Scottsdale Community College; Saba Gerami, and Vilma Mesa, University of Michigan; Irene Duranczyk, Dexter Lim, and Nidhi Kohli, University of Minnesota. Colleges and authors are listed alphabetically.

These courses are often considered a mathematical gateway to a career in science, technology, mathematics, and engineering (STEM) as well as careers in other fields. Among the topics key to future success are linear equations/functions, rational equations/functions and exponential equations/functions—topics typically taught in Intermediate Algebra (IA) and College Algebra (CA) courses at community colleges. These courses are designed for US students who desire to enter a STEM or Business-related field but have inadequate mathematical preparation. In the US, high school graduation requirements vary by state and a student entering a community college may not have had the opportunity to take a course equivalent to IA or CA in high school. In fact, the majority of high school students do not take any mathematics beyond a 9<sup>th</sup> grade algebra course (Champion & Mesa, 2018), a course preparatory to IA. Thus, a student who enrolls in IA or CA either never took the opportunity to complete the work in high school or may have taken one or both of these courses in high school but did not achieve a sufficient level of proficiency to advance. For these reasons, the IA and/or CA courses are unintentional gatekeeper courses for many community college students; hence, our desire to better understand what factors lead to student success.

*Algebra Instruction at Community Colleges: An Exploration of its Relationship with Student Success (AI@CC)* is a National Science Foundation funded collaborative project (Watkins et al., 2016) investigating faculty who teach IA or CA at one of the eight participating community colleges which represent three different regions of the US (Southwest, Plains and Great Lakes). Although topics contained in an IA or a CA course may vary across the participating colleges, our analyses showed a significant intersection of topics within each type of course and across the colleges. Thus, our study focused on instruction around the topics within this intersection.

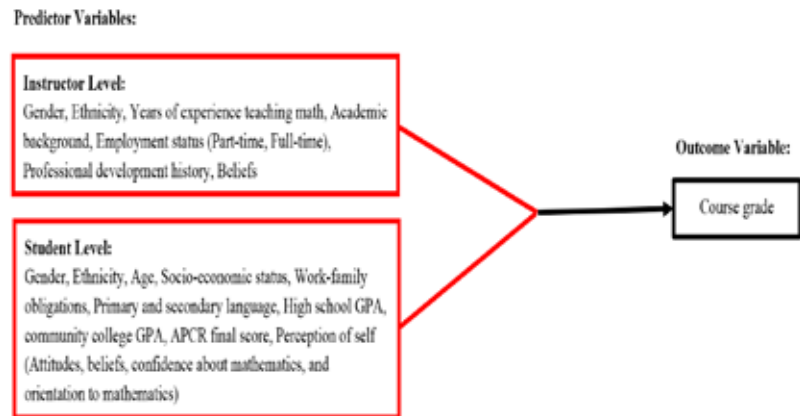

In this observational study we attend to the following three elements: (1) the faculty (who they are, what they believe, what they say, and what they do for planning, enacting, and assessing instruction); (2) the students (who they are, what they believe, what they learn, and how they perceive the instruction they receive), and (3) the content (its richness, how it is organized and presented). Learning in the *AI@CC* study is operationalized as student knowledge at the conclusion of an algebra course, which may be measured by initial tests and final tests, letter grade in the course, and/or their Pass/Fail status. In this paper we share our findings about the relationships between a community college student's knowledge of algebra at the conclusion of a course as measured by course grade, represented by the percentage earned by a student in their community college algebra course, with substantively meaningful student-level and instructor-level variables.

## Methods

Drawing from knowledge generated in K-12 and four-year undergraduate institutions, the *AI@CC* study endeavored to measure variables associated with student learning and performance. Instruments used by the project include the Algebra Precalculus Concept Readiness–Community College (APCR-CC) inventory (Peralta et al., under review), a student beliefs survey (Kloosterman & Stage, 1992), patterns of adaptive learning scales (PALS) survey (Midgely et al., 2000) and teacher behavior inventory (TBI, Murray, 1987; Murray & Renaud, 1995). The psychometric properties of the instruments and the measures resulting from them have been validated (Peralta et al., under review; Peralta, 2017). Additionally, demographic information about students and instructors, students' self-

reported current GPA, and their course grade as both a letter grade and a percentage were collected. We present the results of a model that uses instructor and student level characteristics as predictor variables for course grade (see Figure 1).

This model posits the existence of predictive variables at student and instructor levels that help explain the variation in student learning and performance in the algebra courses. The student-level variables include personal characteristics, APCR-CC final score, and perceptions of self. Instructor level variables include personal characteristics, behavior, knowledge and attitudes towards innovative teaching practices, knowledge of algebra for teaching and beliefs about mathematics.

**Figure 1: The AI@CC model for course grade**

## Measures

*APCR-CC Initial and Final Scores.* This 25-item assessment, measuring a single construct called quantitative reasoning (Peralta, et. al., under review), was created to measure readiness for college-level algebra and precalculus courses. The APCR-CC was administered to students twice in each of the courses observed (IA and CA). Identical versions of the test were administered at the beginning of the Fall 2017 semester (APCR-CC Initial Score) and at the end of the semester (APCR-CC Final Score). Each student's total score was determined by the sum of correct responses (one score per task) for a maximum score of 25.

*Student Beliefs.* The student beliefs survey was created from a survey related to motivation and achievement in the context of problem-solving following work by Kloosterman and Stage (1992). The survey, given at the beginning of the semester, had 36 items measuring personal beliefs. Of the instruments' six beliefs: (1) I can solve time-consuming problems, (2) There are word problems that cannot be solved with simple, step-by-step set procedures, (3) Understanding concepts is important in mathematics, (4) Effort can increase mathematical ability, (5) Word problems are important in mathematics, and (6) Mathematics is useful in daily life, the last two constructs were excluded from the analysis because of their low reliability (Peralta & Kohli, 2017). The score for each construct is calculated as the sum of the scores on the individual items.

*Patterns of Adaptive Learning Scales.* The Patterns of Adaptive Learning Scales (PALS) survey, given mid-semester, has 49 items (Midgley et al., 2000) that "are used to investigate the relation between a learning environment and a student's motivation, affect, and behavior" (Statistics Solutions, 2017). Of the instruments' nine constructs, the predictive model explored here used the three constructs: Academic Self-Efficacy, Student Performance and Teacher Mastery. The score for each construct is calculated as the sum of the scores on the individual items.

*Instructor Level Variables.* Demographic variables at the instructor level including gender, full-time or part-time employment status, and years of mathematics teaching experience. Continuous variables describing the amount of formal math specific professional development, formal non-math specific professional development, and informal professional development were also included. In addition, we incorporated instructional practices, instructor beliefs and instructor knowledge of mathematics for teaching into the analyses. The Mathematical Knowledge for Teaching–Algebra developed by ETS and the University of Michigan as part of the Measures of Effective Teaching Project (Melinda Gates Foundation and Educational Testing Services, 2012) was administered to faculty participants prior to the start of the Fall 2017 semester to measure their knowledge for teaching. The Faculty Beliefs about Mathematics and Mathematics Teaching survey developed at the University of Maryland (Campbell, 1990) was used to gather faculty beliefs. Midway through the semester student perceptions of the instructional practices of their instructor were collected via the TBI (Murray, 1987; Murray & Renaud, 1995), a 56-item instrument that describes the instructional practices experienced by students in the classroom.

*Outcome Variable.* Participating instructors provided the students' final grades as a letter grade and as a percentage from 0 to 1. Scales used to assign letter grades vary by institution, so we chose to continue our analysis using students' percentage grade as opposed to the letter grade for the outcome variable.

## Models

Multiple linear regression was performed to study the effect of student-level and instructor-level variables on the outcome of percent grade. The data used in the model was gathered from 20 IA instructors with 272 students and 24 CA instructors with 365 students across the participating institutions. The main effects in the model, identical for IA and CA groups, were built using the demographic variables, APCR-CC

$$\begin{aligned} \widehat{\text{PercentGrade}} = & \beta_0 + \beta_1(\text{Male}) + \beta_2(\text{Age}) + && \text{Intercepts, Gender and Age} \\ & \beta_3(\text{Hispanic}) + \beta_4(\text{Asian}) + \beta_5(\text{Black}) + \beta_6(\text{Mixed}) + \beta_7(\text{Other}) + && \text{Race or Ethnic Group} \\ & \beta_8(\text{FirstLanguage}) + \beta_9(\text{Caregiver}) + \beta_{10}(\text{Work}) + && \\ & \beta_{11}(\text{GPA}) + \beta_{12}(\text{MinorAssistance}) + \beta_{13}(\text{MajorAssistance}) + && \text{Other Demographics} \\ & \beta_{14}(\text{APCR Posttest}) + && \text{Score on APCR Posttest} \\ & \beta_{15}(\text{DifficultProblems}) + \beta_{16}(\text{Understanding}) + && \\ & \beta_{17}(\text{Effort}) + \beta_{18}(\text{Useful}) + && \text{Student Beliefs} \\ & \beta_{19}(\text{SelfEfficacy}) + \beta_{20}(\text{StudentPerformance}) + \beta_{21}(\text{TeacherMastery}) + && \text{PALS} \\ & \beta_{22}(\text{MaleTeacher}) + \beta_{23}(\text{FullTime}) + && \text{Teacher Demographics} \\ & \beta_{24}(\text{MathPD}) + \beta_{25}(\text{NonMathPD}) + \beta_{26}(\text{InformalPD}) + && \text{Professional Development} \\ & \beta_{27}(\text{TASMD}) + \beta_{28}(\text{TMM}) + \beta_{29}(\text{TASSP}) + \beta_{30}(\text{MKT}) && \text{Teacher Behavior Inventory} \end{aligned}$$

**Equation 1: Regression model for IA and for CA groups**

final score, student beliefs factors, PALS, and instructor level variables (see Equation 1). Student demographics included are gender, age, race or ethnic group, if English is their first language, if they are a primary caregiver, if they are employed at least 40 hours per week, and high school GPA (coded dichotomously: less than 2.5 as 0 and greater than or equal to 2.5 as 1).

## Preliminary Findings

Standardized results for both IA and CA are presented in Table 1. In both groups, APCR-CC final scores and PALS Academic Self Efficacy were statistically significant at a  $p < 0.05$  level. For every one standard deviation increase in APCR-CC final score, on average, the predicted percent grade

**Table 1: Standardized coefficients for linear regression**

increase in Math Specific Formal Professional Development, on average, the predicted percent grade increases by 0.104 standard deviations, and for every one standard deviation increase in Informal Professional Development, on average, the predicted percent grade increases by 0.21 standard deviations for the CA group. There were other variables in either of the two groups that were statistically significant (see Table 1).

The analysis with CA students and with IA students both had adjusted R<sup>2</sup> values that, while not overly large, are considered substantial for an observational study in education (Hill, et. al., 2008). The adjusted R<sup>2</sup> values for the two groups are in the range of 20% – 30%. That is, the model predictors explain 20% – 30% of the variance in the outcome variable, percent grade.

## Discussion

The preliminary results from these analyses suggest that (a) the APCR-CC final score, (b) PALS Academic self-efficacy score, and (c) instructors' years of mathematics teaching experience and exposure to professional development opportunities are positively associated with the students' outcome on course percent grade. The demographics of students taking these courses and the nature of the content taught in these two courses may explain the degree to which the APCR-CC can be used as a predictor and the extent to which these instructor factors affect the students' opportunities to learn.

increases by 0.064 standard deviations in the CA group and 0.089 standard deviations in the IA group, respectively. For every one standard deviation increase in PALS Academic Self-Efficacy, on average, the predicted percent grade increases by 0.197 standard deviations for the CA group and 0.182 standard deviations for the IA group, respectively. Moreover, Years of Teaching Experience was statistically significant for the IA group, where the predicted percent grade increases by 0.091 standard deviations, on average, for every one standard deviation increase in Years of Teaching Experience. For the CA group, both Math Specific Formal Professional Development and Informal Professional Development were statistically significant. For every one standard deviation

Given that the APCR-CC was designed to measure readiness for CA and pre-calculus, it is not surprising that APCR-CC final scores are a good predictor of students' final grades in both courses. Students who were able to do well on the APCR-CC, which tested conceptual understanding, were more likely to do well in their course. What might be surprising are the respective effects of APCR-CC final score increases to the grade increase for both IA and CA group of students. IA students' grades seemed to respond more to APCR-CC score increases than their CA counterparts. This main effect was somewhat tempered in the CA courses, which command a deeper conceptual understanding of proportionality, linearity, covariational reasoning, exponential growth, rational function behavior, and an ability to leverage these ideas to create models for problem solving.

Since the PALS Academic Self-efficacy scale measures academic related perceptions, beliefs, and strategies of the student, it is not surprising that students who have a higher score in the academic self-efficacy scale perform better in their course. Research has shown that a students' self-efficacy appears to be a critical factor for student success and performance with an extensive body of research showing a positive association between academic self-efficacy and college grades (Barber, 2009). Thus, we confirm prior research regarding the role of motivation on performance, with the very specific population of community college students taking algebra courses (Mesa 2012).

The students' opportunities to deepen their understanding of concepts taught in these algebra courses were positively impacted by the instructors' years of teaching experience and exposure to professional development (PD). We posit that duration of teaching experience had a positive impact on the IA course because: (i) the course is calculational in nature, and (ii) students in these courses may be repeating the course (after previously seeing the content in high school). These two factors make years of teaching experience a valuable trait for an instructor teaching this course because the instructor becomes efficient in teaching ways of doing (as opposed to ways of thinking), and instructors can also anticipate students' common pitfalls and offer pre-remediation. On the other hand, exposure to PD had a positive impact on CA students' opportunities to learn. These students are typically encountering the largely conceptual content taught in this course for the first time. IA courses tend to be more about simplifying expressions and solving equations while CA tends to be more about reasoning about and modelling with functions. Thus, teaching IA involves developing students' fluency with algorithms while teaching CA involves developing students' facility with functions, a topic that is historically elusive to students and slow to develop. The complexity of teaching mathematics (Potari, 2012) in ways that develop students' conceptual understanding, especially on elusive challenging topics such as functions, puts extra demands on instructors to teach in innovative ways, that are largely different from the ways the instructors encountered mathematics instruction when they were students. Professional development opportunities, both formal and informal have the potential to positively affect instructors' efficacy (Zambo & Zambo, 2008) by exposing instructors to the nature of mathematics and to effective practices in mathematics education that lead to developing students' conceptual understanding. There is much we still need to learn through our analyses of these instructors' teaching practices, which might shed further light into this issue. For example, we do not know the specific types of PD these instructors were exposed to, or how those PD opportunities impacted the instructors teaching practices. Based on these preliminary results, we recommend increasing PD opportunities for community college instructors, research into

the specific types of PD these instructors are receiving, along with their corresponding impact on teaching and students' learning.

Moreover, all of the instruments (e.g., PALS) and the assessment (e.g., APCR-CC) used in the study were rigorously evaluated to establish the appropriate psychometric properties to ensure that the data collected during the course of the study were both valid and reliable. This psychometric validation process in itself is novel in the field of post-secondary mathematics education. We looked at the effects of each of these instruments and assessment on the outcome variable of percent grade in isolation, that is, after factoring out the variance from other variables in the model (e.g., demographic variables). We found significant effects of APCR-CC final scores, and the subscale - Academic self-efficacy from PALS survey on the outcome of percent grade, along with some other demographic variables. Analyzing each of these instruments and assessment in relation to the others can give us new perspectives on the relationships, which would otherwise be unavailable to us. Viewing research in this integrated way can help with the analysis of important outcomes of interest in a more comprehensive way. These findings have the potential to impact the way we measure student learning and consequently, the development of any professional development for the instructors, and/or student learning interventions. This work strived to provide a more holistic perspective on assessment and may provide direction for future creation of diagnostic assessments/instruments for assessing students in other contexts. Considerations for creating or modifying such diagnostic assessments/instruments for use by the research community should include the diversity of curricula, impact of culture, teaching techniques, and language as well as other factors that impact students' learning differently in different parts of the world.

## Acknowledgements

Funding for this work was provided by the National Science Foundation award EHR #1561436. Any opinions, findings, and conclusions or recommendations expressed in this material are those of the author(s) and do not necessarily reflect the views of the National Science Foundation. We thank the faculty who participated in the project—without them this work would not have been possible.

## Introduction

The Thematic Working Group 22 (*Curriculum Resources and Task Design in Mathematics Education*, hereafter TWG22) was launched at CERME10 in recognition of the growing area of research in the field of curriculum resources (Pepin & Gueudet 2018; Stylianides, 2016), their design and use by teachers and students, and the specific design of mathematical tasks, mostly by teachers acting as designers (Laurillard, 2012; Jones & Pepin, 2016) but also their place in textbooks (e.g., Stylianides, 2014). While this field shares approaches, methods and research topics found in other areas in mathematics education research (e.g. TWG15, 16), it has its own distinctiveness. It focusses on the design and use of curriculum materials (digital and non-digital) for various educational purposes, including the design of classroom-based interventions to promote important but hard-to-teach and hard-to-learn learning goals (e.g., Komatsu, 2017; Saxe, Diakow, & Gearhart, 2013; Stylianides & Stylianides, 2009). Moreover, leaning on work by Pepin, Choppin, Ruthven, and Sinclair (2017), we make here a clear distinction between (digital) curriculum resources and educational technology, as research on (digital) curriculum resources (in the area of mathematics) pays particular attention to

- the aims and content of teaching and learning mathematics;
- the teacher's role in the instructional design and task design process (i.e., how teachers select, revise, and appropriate curriculum materials; how teachers design tasks);
- students' interactions with (digital) curriculum resources in terms of how they navigate learning experiences within a digital or non-digital environment;
- the impact of (digital) curriculum resources in terms of how the scope and sequence of mathematical topics (and tasks) are navigated by teachers and students;
- the educative potential of (digital) curriculum resources in terms of how teachers develop capacity to design pedagogic activities and tasks. (amended from Pepin, et al. 2017, p. 647)

We acknowledge that “curriculum resources” is an elastic term: ranging from particular tasks and activities, over one-off worksheets or tests, to a full-blown curriculum program, and all of these notions were addressed in the different sessions at CERME10 and CERME11.

The role and importance assigned to curriculum resources and task design in the last decades has led to an enormous variety of approaches to research in this area. At CERME10, 17 papers and 6 posters

were accepted, and at CERME11 the number of papers submitted to TWG22 has increased: 22 papers and 8 posters were accepted. In terms of organization, the paper contributions were presented (by the lead author) and discussed (by an ‘independent’ TWG colleague). The presentation/discussion sessions (see below) were followed by parallel table discussions (colleagues could choose which table to join), and finally a plenary, where amanuenses of each table/paper reported back on the main issues discussed.

The sessions were organized under the following six themes (distributed over six sessions):

1. International textbook studies
2. Teacher thinking and competences
3. Task design
4. Digital curriculum resources and task design
5. Particular task design and theories
6. School and workplace mathematics

Although there was considerable overlap between some of the sessions, for clarity we briefly discuss each theme separately below. During the first part of session 7 the eight posters were presented and discussed in a “poster walk”. The second part of session 7 was devoted to a discussion of the issues raised during the six thematic sessions.

Within CERME, the 22 papers and 8 posters presented in TWG22 at CERME11 drew upon research from 25 countries across 4 continents, and offered a wide spectrum of perspectives. Outside CERME, we saw an increase in handbook chapters, special issues, and whole books focusing on the design and use of curriculum resources (e.g. Pepin, Gueudet, Yerushalmy, Trouche, & Chazan, 2016; Pepin & Choppin, 2017; Stylianides, 2014, 2016). At the same time, the work of TWG22 overlapped with research in the field of, for example, digital technology in mathematics education, or teacher education. New conferences have been initiated (e.g. ICMT; MEDA) with colleagues from TWG22 involved in their set-up and as IPC members.

## **Themes and paper contributions**

In session 1 international and comparative research was presented, predominantly related to textbook studies. In two paper presentations (Memis; Ruwisch & Huang) a particular topic area (e.g. reasoning; length measurement) was compared in two countries’ textbooks (Japanese & Turkish textbooks; German & Taiwanese textbooks). Results showed that, for example, in Taiwanese textbooks the emphasis was on concrete actions, whereas in the German textbooks it was on abstract and mental procedures; and the Japanese textbooks provided more “creative” mathematical reasoning opportunities (in the area of proportions) than the Turkish books. A third textbook study of Malawian primary textbooks (Lisnet) examined grade 1 textbooks with respect to mathematical opportunities (with respect to the number concept), whilst teachers’ pedagogical design capacity with respect to using textbooks was investigated in another (Chowdhuri). A comparison of naming systems (of curriculum resources) by Chinese and Mexican teachers was conducted in Wang et al.’s study, which highlighted the problem of conceptual equivalence in international studies (see permeating themes).

In session 2 issues related to teachers’ use of curriculum resources, their lesson planning and related instruction were discussed. Whilst in the paper by Siedel examined teachers’ knowledge of their resource options in order to support and further their design of effective instruction, another group of

researchers (Allsopp, et al.) explored teachers' use of a curriculum framework (involving mathematical competencies) for teaching activities. The team of Delaney and Gurhy investigated task characteristics and teacher practice that supported differentiated instruction and work on challenging tasks.

In session 3 core issues of task design was addressed. These related to the design of tasks with particular characteristics (e.g. self-explanation prompts - Dyrvold & Bergvall); to task design on particular mathematical topic areas (e.g. slope of a curve - Bos, et al.) or with focus on particular challenges (e.g. conceptual and/or creative challenges - Jaeder); to task design fostering students' engagement (e.g. construction of examples on a particular topic – Cusi & Olsher), and to the design of a task progression framework (e.g. Courtney & Glasnovic Gracin).

In session 4 core issues of task design continued to be addressed, also in relation to digital curriculum resources. Whilst the study by Essonnier et al. addressed collaborative design (in an EU project) of a digital resource and the linked social creativity, the study by Eckert and Nilsson investigated the design of digitally enriched classroom talk. In her research Rafalska focused on the teaching and learning of 'algorithmics' in terms of resource design, whilst Geti and Ding examined the use of variation theory for problem-based task design.

In session 5 task designs related to particular theories were examined. These theories included the Hypothetical Learning Theory for the learning of rules for manipulating integers (Schumacher & Rezat) and for the learning of Calculus (Breen, et al.), and the Theory of Conceptual Fields for the analysis of textbooks on the concept of function (Sureda & Rossi).

In session 6 curriculum resource design related to school and workplace mathematics was explored. Studies included those that investigated the 'building of bridges' between school and workplace mathematics (Herheim & Kacerja), and the integration of inquiry-based learning and workplace mathematics into mathematics teaching (Kalogeria & Psycharis).

In session 7 the eight posters were presented. The issues addressed in the posters ranged from those related to the design of the mathematics curriculum (e.g. Solano, et al.) and tools for such design (e.g. Noehr, et al.; Katona); over those linked to task characteristics (e.g. Misailidou & Keijzer; Martin); to teachers' selection and use of curriculum resources (e.g. Kock & Pepin; Varga; Jukic Matic & Glasnovic Gracin).

## **Issues raised across the six sessions**

The sessions were organized under six themes, and naturally issues related to those themes were discussed in those sessions. However, there were also selected permeating strands/themes that ran across the themed sessions. The following themes permeated all six sessions: (1) terminology; (2) teacher learning and student learning; (3) networking of theories; (4) particular theories: hypothetical and actual learning trajectories; (5) methodologies; (6) theory and practice; and (7) context.

## **Terminology**

Questions such as the following were raised:

1. What constitutes a task? - An activity in a textbook? A lesson? A learning trajectory?

2. Where does task design finish? Should implementation be included in the design?
3. When is a task educative for students?
4. When is a task educative for teachers? E.g. in a teacher guide?

The issue of ‘terminology’ (and ‘naming’) was raised in the first session, initially because several comparative studies were presented (e.g. Memis; Ruwisch & Huang; Wang et al.). In the comparative studies the researcher/s have tried to establish ‘equivalence of concepts’, so that they could establish validity of concepts for the comparisons. This was linked to the translation from one language to another, and the meaning making of particular notions, so that the researchers could actually compare ‘like with like’. It was also questioned what it means to design a ‘task’ (see also session 3 and 4): first, is a task similar, or equivalent, to an activity in a textbook, or do we mean a lesson, or even a whole lesson series, when we speak of a task? Second, what does ‘task design’ mean? Is it linked to task/lesson preparation, or is the enactment part of task design? Third, when is a task educative for students, and when for teachers? The issue of “educative materials” (Davis & Krajcik, 2005; Pepin, 2018) was raised, and educative for whom. Clearly, educative curriculum materials for students (e.g. in textbooks) are likely to be different from those for teachers (e.g. in teacher guides that accompany textbooks).

### **Teacher learning and student learning**

Issues and questions such as the following were raised:

- It is often (naively) assumed that students “automatically” learn when using a particularly designed task
  - How do we investigate that?
- How does teacher learning take place when working with tasks and materials?
  - If tasks are developed in a community, how does this affect teacher learning?
- What kind of teacher learning is required for choosing, designing, interpreting, and implementing tasks?
  - What is the possible role of educative curriculum materials?

The issue of ‘teacher and student learning’ links to the above-mentioned questions raised concerning educative curriculum materials. It was discussed in which ways teachers learn when working with curriculum materials (e.g. textbooks; digital curriculum materials) and mathematics tasks. How does one know that teachers learn when interacting with curriculum materials, and as importantly, what do they learn? And if they work in a collective, do they learn more, or less likely, or otherwise? Indeed, it seems to be necessary to establish under which conditions teachers learn best, and with which kinds of curriculum materials. Effective educative materials (for teachers) must have particular characteristics/heuristics.

### **Networking of theories**

Issues and questions such as the following were raised:

- Abundance of theories
  - Activity Theory
  - Variation Theory
  - Theory of Conceptual Fields

- Documental Approach to Didactics
- What are their boundaries/ domains of application/ similarities & differences/ limitations?
- Can they be combined/ networked?
  - Is any combination viable?
- How can they be linked to design principles?

In session 5 particular theories were emphasized as bases for the analysis and design of tasks (e.g. variation theory). Moreover, it was questioned whether particular theories could be combined or networked (e.g. Bikner-Ahsbals & Prediger 2014), and under which circumstances this might be useful. For example, the theory of Hypothetical Learning Theory (HLT, Simon 1995) was seen as a theory supportive of teachers to design a coherent learning trajectory for their students. However, this particular theory might not suffice for defining particular design principles of a learning trajectory; for design principles particular curriculum design tools, or task design principles, would be also be needed (e.g. variation theory). Furthermore, issues related to the use of a theory outside of the context where it was ‘born’ were discussed, and whether a theory might be differently interpreted in different contexts.

### **Particular theories: Hypothetical and actual learning trajectories**

Issues and questions such as the following were raised:

- What do they mean?
  - Issue of singular (trajectory) vs. plural (trajectories)
  - Common/joint/collaborative learning path vs. individual learning path
- What does the comparison of the two tell us?
  - Implications for task design(ers)
- How do they link (or how might they be linked) to design principles?

Linked to the above, it was questioned whether the envisaged hypothetical learning theories would actually develop into actual student learning/study paths (e.g. Pepin & Kock – this conference; Weber, Walkington, & McGalliard 2015), and in which ways the comparison of the two would provide indications of design criteria/principles (for task/curriculum designers) or the efficacy of an intervention (Stylianides & Stylianides, 2009).

### **Methodologies**

Issues and questions such as the following were raised:

- Design (based) research as a methodology tailored to bridging theory and practice.
- How do theories inform methodologies for studying task design, implementation...?
- Are some methodologies better suited to study task design, implementation than others?
- How do we measure effectiveness of the task design, implementation, stability, for example? Is comparison of HLTs and ALTs a viable way to do this?

In terms of empirical research, questions were discussed linked to the ‘measurement’ of the design and implementation of tasks, the design and evaluation of processes expected to help students (and teachers) to develop deeper understandings of the mathematics and its learning (and teaching).

## Theory and practice

Issues and questions such as the following were raised:

- Role of users
  - Teachers as designers
- Researchers and teachers working together
  - Collaboration/cooperation?
  - Role of researcher/s and teacher/s
- How can research findings inform practice and how can practice inform research?

Several studies presented in the TWG22 used a design-based research approach. This methodology was seen to bridge theory and practice, as theoretically underpinned designs/interventions are evaluated in practice, and subsequently re-designed and evaluated in iterative cycles to reach the desired results. One of the questions on design-based research links to the role/s of the designer and users: for example, when do teachers act as designers; when are they the ‘implementers’ of commercial designs (e.g. from textbooks), who are expected to appropriate the design/s, or even enact the design/s ‘with fidelity’? What does ‘teacher design’ mean, and does design include creativity and novel design? Or is teacher design when teachers make small amendments to mathematical tasks during their lessons? Perhaps more importantly, it was questioned in which ways research findings can help teachers in their daily practice of ‘task design’, and how teachers’ practice informs and stimulates research that addresses the issues relevant for teachers.

## Context

Issues and questions such as the following were raised:

- Researchers are often not explicit about particular contexts, and societal influences are sometimes difficult to determine, so are particular teaching cultures (e.g. textbooks – or lack of them – play different roles in different places).
  - What might we be able to infer from a textbook analysis in terms of student learning opportunities in the classroom?
  - Affordances and limitations of textbook analysis
- Exploratory study – are the systems stable? What has changed and what stays the same, when
  - Curricula change?
  - Resource systems vary?
- Technology, and the changes it brings, can render some tasks redundant or unworkable

One of the permeating strands throughout the six sessions related to the context of the design and enactment of curriculum resources. Mathematics teachers work under very different conditions with different kinds of curriculum resources, inside and outside the classroom. In some contexts, textbooks are crucial/mandatory resources, in others teachers prefer to ‘pick and choose’, or design their own materials. In some contexts, teachers can dedicate half of their time to the design of curriculum resources and learning trajectories, in others they are expected to ‘teach by the book’. It became clear that what we measure as researchers might be valid for one particular school or region, or true for a

particular time, but that parameters change with time and context, and hence research only provides glimpses of particular phenomena.

## **Possible directions for future research**

Whilst there was a clear overlap of research themes (and directions) between CERME10 and CERME11 in TWG22 (e.g. task design, plurality of theoretical frames), at CERME11 issues related to international studies and international comparisons emerged as important points for discussion. This also related to theoretical frames, or those that were developed in one context and used in another. Moreover, teacher professional development practices and their work with curriculum resources were compared from one context to another, and this led the way to question the scalability of particular curricular practices and design activities.

The following directions for future research emerged from the discussions in TWG22:

- Understanding better the appropriation of tasks by practitioners (teachers, lecturers) and the impact on students (and teachers) would be a valuable focus. Teacher design often includes appropriation.
- There is additional potential to look at professional development around particular tasks.
- Students and their learning experiences should be included in considerations for task design. They are typically included in design-based research, where selected aspects of student response (to tasks) are often included.
- There is abundant potential to research the notion of ‘task design’, in particular when researchers or task designers let go of designs and hand them over to practitioners/teachers (e.g. in terms of the fidelity to the intended design of the task). Confrey and her team (Sztajn, Confrey, Wilson, & Edgington, 2012) have developed learning trajectories for the common core standards, which have fidelity to the common core curriculum.
- We discussed fidelity of resources that are passed on to teachers, but we have not sufficiently discussed fidelity of design to research on tasks or to the theory used and this may be addressed in future work.
- Scalability of processes was not a strong focus of the working group. The mathematics education community is still more concerned about small groups of teachers implementing tasks. However, for example, Chinese mathematics education research has moved towards scalability of tasks/materials.

# Exploring teachers' assignment of mathematical competencies to planned lessons using Epistemic Network Analysis

Benjamin Brink Allsopp<sup>1</sup>, Jonas Dreyøe<sup>1</sup>, Andreas Lindenskov Tamborg<sup>1</sup>,  
Brendan Eagan<sup>2</sup>, Sara Tabatabai<sup>2</sup>, David Williamson Shaffer<sup>1,2</sup> and Morten Misfeldt<sup>1</sup>

<sup>1</sup>Aalborg University, Denmark, ben@learning.aau.dk;

<sup>2</sup>University of Wisconsin - Madison, USA.

*In this paper, we explore teachers' use of a curriculum framework involving mathematical competencies in planning teaching activities. We have used data from a pilot learning management system and Epistemic Network Analysis to plot a visualisation of a 2D space displaying a network of teachers' associations of mathematical competencies to their teaching activities. We interpret this visualisation to create a conceptual model for how teachers understand mathematical competencies when planning classroom activities.*

*Keywords: Epistemic network analysis, learning management systems, mathematical competencies, teacher planning.*

## Introduction

There is a long history of constructing *theoretical* conceptual models in educational research. In mathematics education in Denmark, there is an elaborated understanding of what characterizes mathematical activity. During the last 15 years, the concept of mathematical competencies has been developed and elaborated (Niss & Højgaard, 2011; Niss & Højgaard, 2002). In this context, these competencies are described as "... a well-informed readiness to act appropriately in situations involving a certain type of mathematical challenge" (Brooks, Greer & Gutwin, 2014).

The Danish Ministry of Education identifies six competencies in the mathematics curriculum for primary and lower secondary (UVM, 2014). *Problem tackling* is about being able to pose and solve mathematical problems, where a mathematical problem is a task where it is obvious that an answer must exist but the method of solution is unclear and can have different outcomes. The *modelling* competency is about being able to analyse, build and utilize mathematical models about other fields. *Reasoning* is about being able to follow and assess mathematical reasoning, and being able to devise and carry out informal and formal arguments as well as understand what constitutes a mathematical proof. Furthermore, it is about being able to think mathematically, where you know what questions could be posed and what answers are expected in mathematical contexts. The *representing* competency, on the other hand, is about being able to utilize different representations and switch between them as well as being able to choose the most meaningful representation. It also includes being able to handle mathematical symbol-language and mathematical formalism. The *communicating* competency is about being able to communicate in, with and about mathematics - to be able to understand and interpret expressions and texts as well as being able to express oneself about mathematics to different audiences. The *tools and aids* competency concerns the ability to operate and relate to tools and aids for mathematical operation, including Information Technology. It is also about being able to meaningfully reflect upon the choice of which tool or aid to use.

Although the individual competencies can be presented separately as above, they are considered to relate. For example, the so-called flower model (Brooks, Greer & Gutwin, 2014; Collins, 2004) depicts competencies as separate petals that overlap towards the centre, or as a set of dimensions, which together encompass the overall mathematical competence. However, the authors of this model recognize it as a purely theoretical development when they claim that “quite obviously it is impossible to produce scientific documentation that this is theoretically and empirically the case” (Brooks, Greer & Gutwin, 2014). In this paper we recognise the competencies framework as a central curriculum resource used to inform mathematics teachers in their practice. We are interested in exploring how a framework like this is understood and utilized by teachers when planning their lessons. And more specifically if it is possible to use quantitative data to develop conceptual models of how teachers relate the mathematical competencies. Hopefully such models would hold the potential to support the critical reflections of individual teachers.

### **Aims, data & methods**

This paper describes a pilot project conducted in anticipation of large amounts of data generated from learning management systems, which have recently been adopted in Denmark. At the time of writing, this data set is not available, and instead, we use an inferior data set with the goal to explore a specific approach to visualizing data, and using these visualisations in hypothesis and heuristic building.

The data set used in this experiment was collected using the Goal Arrow software. The software was specifically designed to investigate the opportunities and challenges of digitally supporting teachers' goal-setting for teaching activities. In the Goal Arrow, ca. 70 mathematics teachers associated one or more of the six mathematical competencies with their various teaching activities. Nothing was done to ensure that the teachers were representative, and the data included both empty submissions and repeated submissions due to a lack of user input validation. The latter was corrected manually, but with a total of only 182 records remaining, the data set here is not expected to support claims to the generality of a derived conceptual model.

In this study, we employ Quantitative Ethnography (Shaffer, 2017) to provide a method where qualitative and quantitative methods blend together completely by grounding quantitative results in a qualitative understanding of data. It aims at theoretical saturation of statistical models and using quantitative results to enable thick ethnographic descriptions (Shaffer, 2017). More specifically we used the Epistemic Network Analysis (ENA) tool which examines connections in data and uses Singular Value Decomposition (SVD) to represent it as dynamic network model that maximizes the variance in the data using a reduced number of dimensions (Shaffer, Collier & Ruis, 2016).

Quantitative Ethnography describes coding as assigning meaning to observable actions or elements of the discourse observed in one context of a specific culture. In this study, the contexts are individual teachers' teaching activities and the coding is done by the teachers themselves when they assign relevant mathematical competencies to their individual teaching activities. In the data, each competency is represented in its own column where its absence or presence in each record of teaching activity is indicated by 0 or 1.

We imported this data into ENA and defined an *ENA set* where we specified the codes (the competencies), the conversations (individual teaching activity records) and the units (which we do

not use here, but allow us to filter and group records in the visualisations). We plotted the ENA set using default settings to produce the visualisation of the competencies' interrelations depicted in Figure 1.

**Figure 1: The space of mathematical competencies**

The plotting uses SVD, which reduces the number of dimensions while still showing the maximum variance of co-occurring competencies (Shaffer, Collier and Ruis, 2016). The first dimension (the x axis) explains the most variance, and the second dimension (the y axis) explains the second most variance in the data. Individual teaching activities become the red plotted points. These seem fewer in number than the 182 records because they often overlap and should not be confused with the nodes in the network. The black plotted nodes in the network represent the individual competencies (codes). The lines between nodes represent co-occurrence of the competencies in teaching activities. The strength of the connections between competencies, determined by their frequency of co-occurrences, is represented using the thickness and saturation of the lines between nodes.

The positions of competencies (the nodes) in this network graph can be used to interpret the dimensions in the space and this can explain the positions of individual teaching activities (red points). This can provide a conceptual frame (Shaffer & Ruis, 2017) to interpret different combinations of mathematical competencies in teaching settings. It is our ability to do this interpretation that becomes the measure of this approach to generating empirically driven conceptual models.

## Interpretation

By looking at the visualisation generated by ENA shown in Figure 1, we identified and used two different approaches to characterizing the axes.

1. For each axis, we look at the nodes with the greatest distance.
2. For each axis, we split the competencies into three groups and compare these groups.

First, we looked at the *opposites* on the y-axis which are *problem tackling* and *communicating*. From the definitions of these competencies, we understand *communicating* to be about being able to communicate in, with and about mathematics versus *problem tackling* which is about working in the nitty gritty with mathematical tasks that require the activation of more than routine skills. It is tempting to tentatively recognize the y-axis as being about “talking the talk” versus “doing actual mathematics”, or using Collins’ (2004) concepts, *interactional expertise* versus *contributory expertise*. But how well is this supported when we consider the other competencies that also vary on the y-axis?

With regards to splitting the competencies into three groups, we overlaid the visualisation with a grid that segregated the competencies, as shown with the dashed lines in Figure 1, such that the following groups on the y-axis were identified: Y1) *communicating* and *representing*, Y2) *modelling* and *reasoning* and Y3) *tools and aids*, and *problem tackling*.

By considering *communicating* and *representing* as a group (Y1) we see something different about the lower end of the y-axis than when we only considered *communicating*. *Representing* is not about saying the “right” things but more about getting the meaning across, by having something stand for something else. *Representing* is therefore concerned with getting the actual meaning across by any means and if necessary by multiple means, and not just to other people, but also to oneself. In other words, the lower end of the y-axis is not categorizable as mere *interactional expertise* but also requires *contributory expertise*. Combined with our understanding of *communicating*, the bottom end of the y-axis seems more precisely to be about describing and explaining mathematical issues, topics or problems in different ways in different situations.

We revisit the other end of the y-axis in the same way as above. By considering *problem tackling* and *tools and aids* as a group (Y3) we do not have to change our understanding of the top end of the y-axis, from when we only considered *problem tackling*. The *tools and aids* competency is about being able to utilize tools and aids in a mathematical context, and being able to choose the right tool for the job. *Tools and aids* are thus like *problem tackling* concerned with working on or with mathematical problems, tasks and so on efficiently. The top end of the y-axis seems to remain something to do with the actual doing of mathematics with a focus on pragmatic and efficient choices of means for mathematical work.

We must still consider the two remaining competencies, *reasoning* and *modelling*, which form the middle group (Y2). However, the interpretation of their positioning does not disturb the understanding of the y-axis discussed above. The position of *reasoning* near the centre of the y-axis can be explained by the perceived need for *reasoning* along the entire y-axis. It is needed both for describing and explaining as well as working with mathematical problems. The position of *modelling* near the centre

of the y-axis can be explained slightly differently as a necessary bridge between talking about problems from other domains, that we want to apply mathematics to as well as being able to work on those problems with mathematics.

By looking at the placement of competencies along the y-axis, firstly with a focus on the extremes and secondly in three groups, we understand the y-axis as representing a continuum from talking about, drawing, describing and explaining mathematics over *modelling* to actually doing mathematical moves, actions, and solutions with tools and aids. A continuum from describing and explaining to doing mathematics.

The x-axis does not in the same way as the y-axis have a clear pair of *opposites* to help us interpret it, but we did attempt to compare the two competencies with the most extreme distance on the x-axis; *communicating* and *tools and aids*. It was tempting to tentatively recognize the x-axis as being about psychology and cognition versus interacting with something tangible or material. But how well is this supported when we consider the other competencies that also vary on the x-axis. We approached this by splitting the competencies into, and interpreting the three groups: X1) *communicating* and *problem tackling*, X2) *representing* and *reasoning* and X3) *modelling* and *tools and aids*.

Considering the competencies *tools and aids* and *modelling* (X3) we first identified for each of these a new concept that a) seemed to relate to its respective competency and b) seemed to relate to the other concept. The definition of *tools and aids* clearly defines it to be very much about technical tools and not about mental tools (e.g. about straight edges and not about theorems). This gave us the concept “materiality”. We interpreted the definition of *modelling* to be an especially map-like portrayal in the sense that it closely resembles (although simplifies) the object being studied. Together, the concepts materiality and map-like suggested something being tangible or close to the world at the right end of the x-axis. Of course, both competencies are not physical objects in the world, they are psychological and cognitive in nature, but there seems to be an immediacy of attention to things outside of a purely mental realm; to material or non-abstract things. Loosely speaking, to things in the world.

The above immediacy of attention to things outside of a purely mental realm seemed much less necessary when we considered the two competencies *problem tackling* and *communicating* (X1). Of course, both *problem tackling* and *communicating* may relate to something in the world beyond mental or linguistic gymnastics, but the necessary immediacy does not seem to be there because *communicating* and *problem tackling* does not to the same degree have to relate to something concrete but can remain in the abstract. Although all competencies are in virtue of being competencies psychological and cognitive in nature, the competencies on the left end of the axis can be more symbolic or interpretive, and less immediately connected to the world. Loosely speaking, to things in the mind.

The remaining two competencies, *representing* and *reasoning*, which make up the middle group (X2) of the x-axis also do not (like the middle group of the y-axis) seem to disrupt our interpretation of the x-axis. *Reasoning*'s position near the middle of the x-axis can (like its position near the centre of the y-axis) be explained in terms of it being needed across the whole axis. regardless of how directly one engages in the world, mathematical thinking requires reasoning. *Representing*'s position near the middle of the x-axis can (like *modelling*'s position near the centre of the y-axis) be explained as a

necessary bridge between the two ends of the x-axis. To be able to apply abstract mathematical thinking or communicate to the world we need to portray the world, but those portrayals need not be as map-like as those used in *modelling*. Other representations are also needed. One of these representations is natural language explanations, which must be considered an important part of the *communicating* competency.

By looking at the placement of competencies along the x-axis in three groups, we understand the x-axis as representing a perceived continuum from working in the abstract to working more directly in the world. We have summarized this as a continuum from “in-the-mind” to “in-the-world”.

Together these considerations allow us to identify the dimension of greatest variance (the x-axis) as a continuum between “in the mind” and “in the world”, and the dimension with the second greatest variance (the y-axis) as a continuum between “describing and explaining” and “doing mathematics”.

## Limitations & discussion

We have discussed earlier that the available data is inferior. The small number of teachers and registered teaching activities, the fact that no effort was made to ensure that the involved teachers were representative, and the uncertainty due to the lack of user input validation, prevent us from drawing confident conclusions.

This paper and our use of Goal Arrow data is a pilot application of the method we have described. The emphasis in this paper is on exploring an approach, and especially the extent to which we can meaningfully interpret the visualisations. Our interpretation of the current data has allowed us (as a hypothesis or heuristics building exercise) to define a space of mathematical competences. In this space, we define the dimension of greatest variance (the x-axis) as a continuum between “in the mind” and “in the world”, and the dimension with the second greatest variance (the y-axis) as a continuum between “describing and explaining mathematics” and “doing mathematics”.

What is most important is that we expect to be able to use ENA for visualizing massively more of the same sort of data when made available from the learning management systems currently being implemented in Denmark. We now have reason to believe that this data and their visualisation in ENA can be interpreted meaningfully. We must recognize that these interpretations are based on what teachers have expressed about their lessons, which may differ from what they have actually planned, and to a greater degree from what is actually enacted in class. However, the process of associating lessons with competencies is well established in Denmark.

Defined spaces like the one above can be thought of as adding user friendliness or simplifying an existing understanding of mathematical competencies; we are looking at a 2D space instead of a six-columned table. However, there is also a sense in which the defined space is a development of an understanding of mathematical competencies in its own right. When the teachers relate the competencies in individual teaching activities, they are adding information. They are pointing at how mathematical competencies are likely to be engaged together. They are also negotiating between the formal breakdown of the competencies and their own understanding of what mathematics requires. Because of this, we can think of these defined spaces as new conceptual models of mathematical competencies developed using leaning analytics.

We can think of these conceptual models as a complement to the competency flower model. Most obviously, they give us another way to think about the competencies. When planning lessons, a space such as the one presented in this paper may work as a tool to support teachers' reflection and discussion on the direction of their teaching activities. Supported interactively, we can imagine teachers aiming their teaching activities at locations in the space, registering teaching activities by associating these locations to teaching activities and compare their teaching activities to those of other teachers' or their own over time. Such empirically driven conceptual models could also potentially support research and policy. For example, they could direct the attention to challenges or differences in the progression of mathematics education. Specifically, it can raise flags for individual grades, that seem to lack certain areas or have significantly different networks.

## Conclusion

In this paper, we consider the context in which mathematical competencies are used in Denmark, and use data collected in the Goal Arrow software, where teachers associate competencies to their teaching activities. We describe the creating of an ENA set and the plotting of a visualisation comprising a 2D space displaying a network based on the co-occurrence of mathematical competencies in teaching activities. Notwithstanding limitations on the data, we attempt a thorough interpretation of the visualisation which allows us to explore the approach as a way of understanding how teachers use the competencies framework in their lesson planning.

*This paper discusses a task, designing a slide, to support the reinvention of the notion of slope of a curve in a point. The field test show that the lesson scenario allows teachers to utilize students' informal models to introduce slope more formally.*

*Keywords: Mathematics education, reinvention, slope.*

### Introduction

Introducing slope of a curve in a point and the derivative to students is a didactical challenge for teachers. It is tempting to choose for an instrumental approach swiftly progressing to differentiation techniques, both easier to teach and to learn. Without conceptual understanding this entails merely meaningless manipulation of symbols and execution of recipes. The meaning of limit, difference quotient and other concepts related to the slope of a curve at a point form serious obstacles for students (e.g. Tall, 2013; Zandieh, 2000).

This paper discusses an attempt to deal with these obstacles inspired by design heuristics from the theory of Realistic Mathematics Education (RME) suggesting that a way for students to learn mathematics in a meaningful way is to involve them in a process of reinvention (Freudenthal, 1991). A common approach in RME is to introduce a new concept through a task of which the context provides opportunities for students to focus on reasoning and representations related to the notion aimed at. As Gravemeijer and Doorman (1999) state it

The students should first experience a qualitative, global, introduction of a mathematical concept. This qualitative introduction then should create the need for a more formal description of the concepts involved. (p. 113)

This study reports initial experiences of an attempt to support students in (re)inventing the notion of slope of a curve in a point and related representations (e.g. Zandieh, 2000). Students, collaborating in groups of three, are asked to design a slide consisting of a bended and a straight part joining *without bumps*. The desired outcomes are concrete equations describing a line and a curve that meet smoothly (imagine the purpose is to feed these equations into a 3D-printer to print the slide). The task aims for students to discuss what it means for the line and curve to meet in a not-bumpy, i.e. smooth, way. They should search for methods to design a slide and to decide to what extent smoothness is achieved. The hypothesis is that they will come up with ideas that are essential to the notion of slope of a curve in a point. Informal building blocks, meaningful to the student, that can be used by the teacher to afterwards introduce the slope of a curve in a point more formally.

The context of the task is a non-kinematic one. Previous research (e.g. Doorman, 2005) exploited kinematic contexts. Historically this approach makes sense, given the origin of the notion of derivative in mechanics. The presence of dimensions (like meters/second) helps to understand the meaning of slope and more generally to make a connection from derivative in mathematics to the physics curriculum. The slide-context offers opportunities that are not present in the kinematic approach. Students have a tactile and visual understanding of what it means for a surface (or better, a curve) to be *smooth*, as also pointed out by Tall (2013). He suggests students slide their hands along a curve to sense the changing slope. The slide task allows students to mathematize this tactile and visual experience. A main merit of the slide task is that it is formulated in a very *open* way: it allows for various approaches by students. We discern three options: the standard textbook approach through secants of the curve, the locally linear/linear approximation/”zooming in” approach (Tall, 2013), and a (more algebraic) approach based on local bounding lines. The most important advantage of the slide task is that it allows the teacher *connect the student’s work to any or all of these approaches*, depending on what students produce, possibly providing *multiple views on the notion of slope*.

The design of the lesson plan (scenario) for the task is based on the Theory of Didactical Situations (TDS) (Brousseau, 2002). We investigated whether combining RME and TDS as frameworks for the design of an inquiry based mathematics lesson can lead to a successful scenario. This approach of combining ideas from RME and TDS to task design for inquiry based mathematics teaching (IBMT) is pioneered in the Erasmus+ project Meria (Winsløw, 2017).

The research question addressed in this paper is: How do RME-inspired task characteristics and a TDS-inspired teaching scenario support students’ invention of the notion of slope of a curve in a point?

## **RME perspective on the slide task**

The design of the task originates from the RME-principle of a *didactical phenomenology* (Freudenthal, 1983) of the slide context:

What a didactical phenomenology can do is ... starting from those phenomena that beg to be organized, and from that starting point teaching the learner to manipulate these means of organising. (Didactical phenomenology of mathematical structures)

The challenge of realizing a smooth connection in the slide context is a phenomenon that begs to be organized by the tangent line. Visually at first, but then it begs for symbolic means to decide whether the candidate line and curve really join in a smooth way. Some questions that arise are: *how good is the slide at begging?* Does it lead students to mathematize in direction of the learning goal, or even reinvent the slope of a curve at a point? What can be expected from students can be explained using the *emergent models* design heuristic (Doorman & Gravemeijer, 2009). The context-problem is expected to invite students to develop their own situation-specific solution methods. These methods will have to be discussed and compared. A (situational) model expected to emerge from the slide task is that of the slope of a curve at a point as the slope of a tangent line. This is a model *of*, produced after one episode of mathematizing. At best, this is a starting point for further mathematizing towards symbolic and computational aspects of the slope at a point and the derivative.

## The slide task as a TDS-scenario

How to organize the classroom for a reinvention activity? Freudenthal (1991) claims that “guiding means striking a delicate balance between the force of teaching and the freedom of learning” (p. 55). TDS might provide a suitable framework to balance the two. Central to the theory is the difference between didactical and adidactical situations (Brousseau, 2002). In a didactical situation the teacher acts intentionally to share his knowledge. In an adidactical situation the teacher purposefully withdraws, leaving space for students to develop their own activities. Students need this space to invoke their own meaningful strategies to address the slide problem.

For Brousseau it served another purpose: to change the expectations the students and the teacher have of each other. He calls it *finding a new didactical contract*. During this adidactical situation the teacher cannot be expected to be involved in the mathematizing process. Instead (groups of) students interact with the *milieu*. For the slide task the milieu consists of the problem itself together with the artifacts that may be needed to tackle it, for example GeoGebra.

The slide task lesson plan is set up according to phases from TDS and starts with the teacher explaining the problem and introducing artifacts that can be used to work on it. Then the teacher symbolically hands over the milieu to the students and withdraws. What follows is an adidactical *action phase* of 20 to 30 minutes. In this phase students work on the problem in groups of three. They may apply any approach they think is useful. The teacher, even though not interacting with the students, is not inactive: she registers solution strategies from the students and identifies examples that might be used in the following *formulation phase*. The teacher makes sure that for groups that have different strategies one student explains their approach on the blackboard. Then follows a *validation phase*. The teacher asks: “are some solutions better than others? Is there a best solution? How do you know?”. The classroom discussion that these questions provoke form the input for the last phase: the *institutionalization phase*. In this phase the teacher is expected to be able to organize the ideas and strategies presented by students into solution models of the slide problem. The teacher makes a start with transforming the emerging *model of* the situation produced by students into a *model for* mathematical reasoning.

## Method

*Context.* This task was conceived during a project meeting of the Erasmus+ project Meria on inquiry based mathematics teaching. A working group designed a detailed scenario describing teacher and student activities and possible solution strategies.

*Procedure.* The data for this pilot include self-reports, including students work, of pilot lessons by three Dutch teachers (from now on referred to as teacher A, B and C). Teacher B is involved with the whole Meria project as a teacher who performs pilots; the other two teachers signed up for the course after reading about it in a national newsletter. They were trained to give the lesson in a three hour course taught by the authors. In the course we had a try-out of the scenario and discussed the scenario in detail. The potential of the adidactical phase(s) was stressed as this is an uncommon position for teachers to be in. At some point in the following four weeks they taught the lesson. After the lesson

teachers assembled the work of the students and wrote a report including their observations and experiences during the lesson. In a second meeting, after those four weeks, we discussed the experiences of the pilot and their reports with the teachers.

Other data is the self-report on a pilot conducted by the first author.

### *Analysis.*

In an a priori analysis we discerned three hypothetical student approaches, based on three formal approaches to the tangent line. In the a posteriori analysis, we consider signs or traces of each approach as an indicator of a *situational student model*, which may later be *vertically mathematized* into a more formal mathematical model given by the definition.

1. (Bounding line approach) Students choose a free line and then move (translate and rotate) it until there seems to be just one intersection point in the area of focus. This informal approach relates to a formal definition of the tangent line as a unique local bounding line (this we will explain more precisely in the continuation of this research project).
2. (Secant lines approach) Students choose one point on the curve, the intended point of tangency. Then they choose another point on the curve, draw the line between the two points, and move the second point closer to the first (this works best in Geogebra or similar) to obtain a smoother fit. This informal approach relates, of course, to the standard school book approach of the tangent line and slope.
3. (Linear approximation approach) Students choose one point on the curve, draw a line and then try to adjust the slope so that it fits best against the curve (perhaps by wiggling their ruler). In GeoGebra or similar this can be done by moving the second point needed to draw the line. This informal approach relates to the more formal approach of the tangent line as the best linear approximation at a point of the curve (this will also be explained more precisely in future work).

The main distinction between the approaches is in the way the smoothness of the slide designs is evaluated or controlled by the students in the slider context: (1) by looking for intersection points, (2) by moving the point closer and closer and (3) by looking for intuitive smoothness. If students allow GeoGebra to compute the intersection point of the line and the curve, then approach 1 and 3 will resemble approach 2, since they will see the two intersection points approaching each other as they move closer to the desired line. In approach 1 students fix the slope and search for corresponding point, whereas in approach 2 they fix the point and find the corresponding slope. In approach 3 both options are present.

After students have drawn some lines and curves and written corresponding equations, they will have to find out whether their solution is ‘smooth’ enough. In a second a priori analysis, of what might be discussed by the students and/or the teacher in the validation phase, we expect three possible ways for students to evaluate their own design (in line with Zandieh, 2000):

- I. (Visual). Some will rely on their visual evaluation of the design: if it looks good, then it is good. Students may also choose to zoom in on the curve (work on a smaller scale), for example

- using GeoGebra or similar, to check whether their fit is smooth. Zooming in the curve should more or less coincide with line (see the Locally Straight Approach in Tall 2013).
- II. (Algebraic). The students may compute whether their system of equation has the intended intersection point as a solution. Moreover, students could try and compute that there is *precisely* one solution to the system of two equations (at least locally). For example, if the curve is described by  $y = x^2$  and the line is translated, so  $y = x + b$ . Finding the value of  $b$  for which the discriminant of the equation  $x^2 = x + b$  is zero, gives the desired line. For general algebraic curves one could study for which value of  $b$  the intersection point has multiplicity  $\geq 2$ .
  - III. (Numerical). As a continuation of the second and third approach it would seem natural to choose the second point very close to the first and see how the slope of the obtained line compares to the suggested line. For example, if  $y = x^2$  and  $y = 2x - 1$ , the line through  $(x_0, y_0) = (1, 1)$  and  $(x_1, y_1) = (1.001, 1.001^2)$  has a slope very close to 2. Students may even study a sequence of points  $(x_1, y_1)$  ever closer to  $(1, 1)$ , which would bring them very close to the definition of a derivative through the difference quotient.

We collected the work of the students. In some cases that was individual paper work, but in most cases groups handed in one A4 with their notes and solutions. Furthermore, the teachers reported about the lessons, what they observed during the action phase, to what extent they were able to follow the scenario and what they saw as main results of the lesson. We analyzed the data for occurrences (of traces) of approaches 1, 2 and 3 during the action phase. In addition, these resources were used to find occurrences of the evaluation methods I, II and III during the *action phase* and *validation phase* (possibly the teacher introducing them during a *didactical validation phase*). These traces were used to hypothesize what informal situational mathematical models emerged from the students' work.

Finally these observed approaches were analyzed for their connection to what the teachers reported to have *institutionalized* in the final phase of the lessons. In particular, we tried to decide whether the potential in the students' work was seen and used by the teacher.

## Results

We discuss the work of some groups that represent various observed approaches. A group of grade 8 pre-university school students from teacher A used approach 1: in GeoGebra they translated the line with fixed slope until it seemed to be tangent to the hyperbola  $y = \frac{10}{x}$  (see Figure 1). The suggested line has equation  $y = -x + 6,4$ . This looks acceptable (evaluation method I), but actually the two intersection points are approximately 2 apart. Clearly these students have neither computed the intersection points (algebraic evaluation) nor zoomed in on the graphs (enhanced visual evaluation).

Figure 1. Sample student work

The teacher reports that students mention that they are looking for the line such that there is one intersection point. So these students' informal model of the situation relates to the bounding line definition of tangent line. The teacher writes in her report that she is disappointed that the students did not arrive at the notion of slope of a curve at a point. But, in this case, in the institutionalization phase the teacher could have used the students' explanation of their strategy and the fact that students mention that they are looking for one intersection point to discuss the tangent line as a bounding line. Next, with the students, she could discuss evaluation method II as a step towards the target knowledge. This makes clear that there is a difficulty for teachers to realize the potential in the informal solutions students present. The challenge is to relate students' models to the target knowledge.

A group of grade 10 vocational school students from teacher B draws a tangent line to  $y = x^2$  at the point  $(-2,4)$  (see Figure 2). First they seem to have drawn a secant line through  $(-1,1)$  and  $(-2,4)$ , but this is then dismissed for the sequel. They somehow come up with a  $\Delta y = 5.7$  for this candidate tangent line on the interval  $[-3, -1]$ . They compute the slope of the line. What follows is unfortunately nonsense, but nevertheless the teacher was very excited about their approach and let them present it at the blackboard during the formulation phase. Rightfully so, since these students' informal solution method is precisely the model one needs to introduce the slope of a curve at a point. The teacher writes in her self-report: "The notion of ... slope in a point became meaningful".

Figure 2: Sample student work

Another group from teacher B goes through a sequence of improved slide designs (see Figure 3). The first one has an asymptote; students write "does not have a straight bit". The second one is correct, but is dismissed, because the straight bit is horizontal instead of going up. The third is still with decimal coefficients, but the next four all are clearly attempts at exact solution (5 and 6 the same). Their approach can be classified as type 3. Teacher B told the class that zooming in was a good idea, so all students had a means of evaluating their solutions (method I). What happens in the last attempt is a "nice number wonder": by choosing nice numbers  $-2$  and  $\frac{1}{2}$  the students hit the bull's eye.

Teacher C did not formulate the task properly. She said: "Figure out in groups which functions could describe this curve". As a consequence, most students did not work with a line and a non-linear curve and the teacher got stuck trying to institutionalize the target knowledge as aimed for in the scenario.

Figure 3: Sample student work

The first author performed a pilot study with twelve grade 9 pre-university students equally divided in three groups. One group made drawings of circle segments and approximate tangent lines, using that the radius is perpendicular to the tangent. Within a few minutes they say: "the slope of the tangent line is important". Then they solve the problem by choosing a circle  $x^2 + y^2 = 2$  which goes through the point  $(-1, -1)$ . For this point they infer that the slope of the tangent line is -1 (also visually obvious), which leads them to the equation  $y = -x - 2$ . This group's approach seems to be a case of vertical mathematization. Tangents to circles were already meaningful to them and for them solving the problem easily changes into symbolic work: doing some computations. After they showed the teacher their solution, he asked them to find a solution using a parabola. Their quick solution was a vertical line ( $x = 0$ ) and a parabola ( $x = y^2$ ). Then they asked: "How can you decide the right slope for a different point on the parabola?". This was a very welcome question, later referred to by the teacher in the institutionalization phase.

Another group quickly decided they wanted to use a tangent line with a parabola and a line design and surprisingly knew the algebraic way (II) to evaluate it: using the discriminant to decide whether the intersection point is unique. It turned out that the class made an exercise about exactly this a few weeks ago. Still the group took a long time to decide on a suitable line, finally settling for a correct one. According to the students this was obtained by guessing!

In the institutionalization phase the teacher used the students' solution strategies and remarks to stress the importance of the slope of the tangent line (both in the circle solution and parabola solution). He explained this was called the slope of the curve at a point. With the students they decided that for a circle they could compute the slope in every point, but for the parabola new techniques would be necessary. This would be the subject for later lessons.

## Discussion

Did the task and scenario provide opportunities for students to "experience a qualitative, global, introduction" to the slope of a curve in a point, as was the goal of the task? More concretely: did students come up with ideas that are essential to the notion of slope of a curve in a point? Based on the observations above one could conclude the students did.

Two ideas that are essential to the notion of slope did not come up naturally for students in the pilot. Firstly, the secant lines approach (2) did not occur in any of the pilot lessons, neither did any numerical evaluation of the design (III). This indicates that for the students in the pilot this approach does not come naturally (given the current Dutch curriculum and the task). Many students do have a dynamical approach, in the sense that they try to improve their initial and following attempts by varying parameters of the curve or the line to end up with a (visually) seemingly smoother result. But using two points on the curve to construct such a sequence of better and better fitting lines seems not a natural idea to come up with. On the positive side: the dynamical approach of "improving on your previous line" is a first step toward understanding the tangent line as the result of limit *procedure*. Secondly, the idea of *zooming in* or *changing scale* as an evaluation method has not occurred naturally to students. Once told by teacher B, students immediately grasped the idea and could use it, but they did not reinvent it. Students seem to prefer to stick to the scale at which they drew their first picture and work with reasonably nice numbers within that scale.

If students discover that some of their solutions have two intersection points, in the institutionalization phase the teacher could try and use this discovery to form a bridge to approach 2 and the difference quotient. As soon as you have two intersection points the idea of moving one of them to find a new line is a reasonable step.

A more radical conclusion in line with RME principles would be to go with the students' informal models all the way, instead of trying to facilitate a bridge towards the traditional way to introduce the slope. If the students' approach suggests the bounding line definition of a tangent line is the more meaningful for them, then the teaching sequence should be based on it. One can design instructional sequences following on approach 1 and 3 (in addition to existing sequences based on approach 2). These questions will be topic of study during the next steps in the context of this project.

Finally, in this project we combined principles from TDS and RME. This experience showed that the TDS emphasis on organizing didactic and adidactic phases by a teacher, in connection with the RME principle of reinvention guided by emergent models during these phases, supported the design of an inquiry-based scenario for students.

### Acknowledgment

The authors would like to thank the members of the Meria project-team for their contributions to the development and evaluation of the slide task.

*We present a hypothetical learning trajectory for a sequence of tasks designed for a calculus module. The purpose of the tasks was to give undergraduates opportunities to use technology to experiment and make conjectures while developing their understanding of the effects of translations on graphs. We consider data from task-based interviews with two students. The hypothetical learning trajectory for this sequence of tasks is compared with the actual learning trajectory of the students, and we conclude there was some evidence that our learning goals were achieved.*

*Keywords: task design, undergraduate mathematics; conjecturing.*

## Introduction

The types of tasks that students work on can influence the reasoning and learning processes in which they engage (Jonsson, Norqvist, Liljekvist, & Lithner, 2014). In Ireland, recent studies have highlighted that the majority of tasks both in secondary school textbooks and in undergraduate calculus modules could be solved with imitative reasoning, that is by memorization or following a familiar algorithm (O'Sullivan, 2017; Mac an Bhaird, Nolan, Pfeiffer, & O'Shea, 2017). In this context it is important to design tasks which give students opportunities to develop higher-order mathematical thinking skills, such as conjecturing and generalizing, to move them away from rote-learning. The first and last authors (Breen & O'Shea, 2018) designed a framework of task types for undergraduate calculus modules with the aim of developing mathematical thinking skills such as those suggested by Mason & Johnston-Wilder (2004, p. 109). Subsequently, interactive versions of some of the tasks were developed using the dynamic geometry software GeoGebra. In this paper we will consider a hypothetical learning trajectory (Simon, 1994) for a set of two conjecturing tasks designed using Geogebra on the topic of graph transformations and present data from task-based interviews to explore the actual learning trajectories engendered by this sequence of tasks.

## Theoretical Framework

### Task Design

The framework of mathematical task types used here has six task types: evaluating mathematical statements; generating examples; analysing reasoning; visualizing; using definitions; conjecturing and generalizing (Breen & O'Shea, 2018). We will focus here on the last of these; we will first review the literature to present a rationale for this task type and for using technology in the design.

The acts of conjecturing and generalizing are well-known to be part of the tools of a professional mathematician (Bass, 2015); indeed, Bass describes the progress of most mathematical work as starting with exploration and discovery, then moving on to conjecture, and finally culminating in proof. He identifies two phases of reasoning here: *reasoning of inquiry* (incorporating exploring and conjecturing) and *reasoning of justification* (rooted in proof). The acts of conjecturing, generalising, experimenting and visualising are included in the list of processes which aid mathematical thinking

given by Mason and Johnston-Wilder (2004); these authors also discuss ‘natural’ powers that learners possess such as the ability ‘to imagine and detect patterns,..., to make conjectures, to modify these conjectures in order to try to convince themselves and others’ (Mason & Johnston-Wilder, 2004, p. 34). They stress the importance of creating a ‘conjecturing atmosphere’, so that students can participate in inquiry and develop their mathematical thinking skills.

Dreyfus (2002) defines generalizing as “to derive or induce from particulars, to identify commonalities, to expand domains of validity” (p. 35). He acknowledges the important role played by generalizing in the process of abstraction, in moving from a particular instance to a generality, and notes the difficulty that many students have with generalization. Swan (2008) explains that the process of identifying general properties of a concept from particular cases is one with which a student must be able to engage in order to come to truly understand a concept.

Breda and Dos Santos (2016) examined how GeoGebra tools can enable students to conjecture and provide mathematical proof, and recommended such tools be used to support the study of complex functions. The use of technology has a number of advantages: for instance, information can be gathered and processed quickly so that teachers and students can make decisions efficiently to exploit learning opportunities; moreover, the burden of computation can be removed or reduced to allow students to explore and experiment. Borwein (2005) described specific benefits of the use of technology to mathematicians, including: to gain insight and intuition, to discover new patterns and relationships, to expose mathematical principles through graphs, to test and falsify conjectures, to explore a possible result to see if it merits formal proof, to do lengthy computations. All of these have an important role to play in responding to a conjecturing/generalizing task.

### **Hypothetical Learning Trajectory Construct**

Simon (1995) introduced the notion of a hypothetical learning trajectory (HLT) as part of a model of mathematics teaching. The HLT is made up of three parts: learning goals (as set by the instructor); learning activities (designed or selected by the instructor); and the hypothetical learning process (the instructor’s prediction of how student thinking will develop during the learning activities). Simon describes the symbiotic relationship between the learning activities and the hypothetical learning processes – the ideas which underlie the learning activities are based on the instructor’s beliefs about student learning, and these in turn are influenced by what is observed during the learning activities. Thus theory informs practice and vice versa.

Simon and Tzur (2004) advocate the use of HLTs in task and curriculum design (especially for ‘problematic’ topics) as a mechanism to ensure that adequate thought is given to how student learning might evolve during activities, and as a means to study the success of learning activities. The HLT construct has been used to study teaching tasks and sequences of tasks in a variety of settings including undergraduate mathematics courses. Andrews-Larson, Wawro and Zandieh (2017) note that HLTs are useful ways of tying theory to practice, and use the notion of HLT to outline how certain tasks could lead to undergraduate students developing new understanding in Linear Algebra. Stylianides and Stylianides (2009) compared HLTs and actual learning trajectories to provide evidence that an instructional sequence of tasks had achieved the desired goals.

## Our Task Sequence and Hypothetical Learning Trajectory

We will consider the HLT for our task sequence and the actual learning progression of two students.

### Learning Goals

Eisenberg and Dreyfus (1994) discuss the fundamental importance of developing 'function sense' with undergraduate students. They describe facets of this as including dependence, variation, co-variation and the effects of operations on functions. One of the most important components of function sense is the flexibility to move between multiple representations of a function. The key to solving many problems is to think of them visually, using a graph - including problems encompassing the main facets of functions mentioned above. However, Eisenberg and Dreyfus report that many students (even those more advanced mathematically) are reluctant to do so.

The function operations that we focus on in this paper are graph transformations, specifically vertical and horizontal translations of the graph of functions from  $\mathbf{R}$  to  $\mathbf{R}$ . The learning goals are:

1. observing and articulating the effects of translations on graphs: in particular, describing the relationship between the graphs of  $y = F(x)$  and those of  $y = F_i(x)$  for  $i = 1, 2$  (where  $F_1(x) = F(x) + a$  and  $F_2(x) = F(x + a)$ );
2. observing that, in general, the functions  $F_1(x)$  and  $F_2(x)$  are different when  $a \neq 0$ ;
3. making conjectures, in particular generalizing data from examples observed;
4. using the technology to undertake experiments.

Note that we have both local (1 and 2) and more global (3 and 4) learning goals for student reasoning and skill development arising from our task sequence. Goal 1 targets the flexibility to move between representations of a function. The goals of the task sequence do not include students providing proofs for their conjectures since our tasks deal with Bass's (2015) *reasoning of inquiry* rather than *reasoning of justification*.

### The Task Sequence

For the last number of years, we have been developing a bank of tasks using our framework. Originally these tasks were paper-based and aimed to give students opportunities to explore, spot patterns, and make conjectures based on their observations. We noticed that some students had difficulties drawing the graphs of the functions mentioned and so were not able to generalize or make a conjecture. In 2016, we redesigned these tasks using GeoGebra; we will refer to these as Tasks A and B. (Task A is shown in Figure 1 and Task B is similar except with  $f(x) = (x + a)^3$  etc.). The computational burden was thus removed from the students and we hoped that this would allow them more freedom to experiment and conjecture appropriately. In contrast with the paper-based tasks, the use of GeoGebra allowed us to enable students to quickly see graphs of the form  $y = F(x) + a$  (**Task A**), and  $y = F(x + a)$  (**Task B**), for values of  $a$  ranging over an interval. Both tasks, and others from this project, can be found at <http://maths1r.teachingandlearning.ie/GeoGebra/>.

### Hypothetical Learning Progression

As students engage with the task sequence we expect the following activity and learning from them:

- experimenting with the sliders;

- noticing how the graph of the function  $f$  changes as  $a$  changes, in particular noticing the difference in behaviour for positive and negative values of  $a$ ;
- remarking in the case of Task A (respectively Task B) on the vertical (respectively horizontal) shift of the graph and expressing the relationship between  $f$  and  $f_1$  (respectively  $f_2$ ) mathematically;
- noticing analogous relationships in the cases of  $g$  and  $h$  to identify a pattern;
- using the data from  $f$ ,  $g$ , and  $h$  to make a conjecture about the effects of transformations of the types in Task A and B on graphs;
- amalgamating the relationships observed to realise that, in general, the functions  $f_1(x)$  and  $f_2(x)$  are different when  $a \neq 0$ .

**Task A:** (GeoGebra Task) Use the slider on each graph to change the values of  $a$  in the functions  $f(x) = x^3 + a$ ,  $g(x) = \frac{1}{x^2} + a$ ,  $h(x) = 3^x + a$ .

- What is the relationship between the pair of graphs  $y = f(x)$  and  $y = f_1(x)$  below?  
[The graphs of  $y = f(x)$  (with  $a$  initially set at 1) and  $y = f_1(x) = x^3$  are shown as well as a slider which allows  $a$  to range from -5 to 5. When the value of  $a$  changes the graph  $y = f(x)$  changes accordingly.]
- What is the relationship between the pair of graphs  $y = g(x)$  and  $y = g_1(x)$  below?  
[The graphs of  $y = g(x)$  (with  $a$  initially set at 1) and  $y = g_1(x) = \frac{1}{x^2}$  are shown as well as a slider which allows  $a$  to range from -5 to 5.]
- What is the relationship between the pair of graphs  $y = h(x)$  and  $y = h_1(x)$  below?  
[The graphs of  $y = h(x)$  (with  $a$  initially set at 1) and  $y = h_1(x) = 3^x$  are shown as well as a slider which allows  $a$  to range from -5 to 5.]
- Can you make a general conjecture about the relationship between the graphs of  $y = F(x)$  and  $y = F(x) + a$  from your observations about the graphs of the pairs of functions above? What happens when  $a > 0$ ? What happens when  $a < 0$ ? What happens when  $a = 0$ ?

**Figure 1: Task A**

### Data collection and analysis

In order to investigate the use and effectiveness of the tasks, the second author carried out a series of task-based interviews with a sample of students from a first-year calculus module in which some GeoGebra tasks were trialed. Four students were asked to think aloud while completing a selection of the tasks. Pre and post-tests, each consisting of the same four questions (where one question had two parts), were used at the beginning and end of the interviews in order to help determine if the students' mathematical thinking had changed as a result of completing the tasks. The interviews, which lasted about an hour, used purpose built software to record video, audio, screen and mouse movements. Each student completed between four and seven GeoGebra tasks depending on how quickly they moved through them. The interviews were transcribed by the second author using the audio recording to which she added a summary of what was happening onscreen at that time. The transcriptions were analysed for significant incidents by two of the three authors, and their results were compared and agreed on.

## Results

We will consider in some detail the responses of two of the three students who completed the pre-test, then worked on Tasks A and B in the task-based interviews, and subsequently completed the post-test (see Table 1 below). One question which appeared on the pre-test and post-test was the following:

Q4(ii) Suppose  $f(x)$  is a function defined for all real values of  $x$ . Decide if the statement is true or false. Explain your answer. *If  $a$  is any real number then  $f(x+a) = f(x)+a$  for all values of  $x$ .*

All three students answered Q4(ii) correctly on the post-test but two of them (given pseudonyms Áine and Seán) gave incorrect answers on the pre-test.

Student	Q4(ii) on pre-test	Task A	Task B	Q4(ii) on post-test
Áine	Says ' <i>It's a function</i> ' and writes 'true'. Later she says she thought that the question was asking whether the expression $f(x+a)=f(x)+a$ describes a function.	Is able to verbalise the relationship between the graphs and is able to make the expected conjecture.	Is able to verbalise the relationship between the graphs and is able to make the expected conjecture.	Writes: if $a=0$ but not for other values of $a$ . Explains by referring to the GeoGebra tasks.
Seán	Writes 'True' and gives example with $f(x)=x$ , $a=1$ , $x=1$ . Later when asked what he thought this question was asking: <i>I took it as a set [particular] function rather than an arbitrary function.</i>	Notifies that the y-intercepts of the graphs of $f$ and $h$ depend on the choice of $a$ . For $g$ , he notices that the horizontal asymptotes depend on $a$ , (but does not use correct terminology). Is able to make the expected conjecture.	Notifies that the x-intercept varies according to choice of $a$ . (He calls it the origin). Is able to make the expected conjecture.	Says the statement is false and explains by referring to graph transformations.

**Table 1: Student responses in task-based interview**

Both Áine and Seán were able to use the sliders to obtain graphs of the different translations of the functions in question. Áine worked quickly on both tasks (she spent 2-3 minutes on each of them), she spotted the pattern and was able to verbalise it using mathematical language. For the first pair of functions on Task A she said:

So as I can see here as I am taking values away from  $x^3$  the graph shifts down the y-axis and as I add values it shifts up the y-axis.

She did the same for the graphs of the translations of  $g$ , predicted what would happen with  $h$ , and was able to conjecture:

when  $a > 0$  the graph of  $f$  moves up the y-axis and when it's less than zero it moves down.

Similarly on Task B, she was able to use the slider to generate vertical translations of the three functions, and she made a conjecture generalizing the pattern she observed.

Seán spent about 6 minutes working with the three graphs on Task A. He used the slider to examine how the functions changed for the range of values of  $a$ . He also was able to spot a pattern but focused on certain features of the graphs instead of the whole graph; for the translations of  $f$  and  $h$  he spoke about their y-intercepts (but used the term *origin*), and for the translations of  $g$  he noticed that the horizontal asymptotes depend on  $a$  (but did not use this term). For the general conjecture he scrolled back to the first pair of graphs, moved the slider, then looked at the other pairs of graphs:

All the graphs shift upwards in the  $y$  direction by the value whichever value  $a$  is from the original position of  $y = f(x)$ . When  $a < 0$  all the graphs shift down in the  $y$  direction by whatever value  $a$  is in the... by whatever value  $a$  is from wherever  $y = f(x)$  happens to be.

Seán worked through Task B in a similar manner for about 6 minutes. However, when asked to give a general conjecture this time Seán gave an appropriate response immediately without having to scroll back up through the three functions, as he did for the general conjecture in Task A.

## Discussion

We have only presented evidence from two students who worked on a pair of conjecturing/generalizing tasks. However, from these case studies, we can draw some conclusions for these students' learning. Our data suggests that both students achieved learning goals 1, 3 and 4 as they were able to use the technology to experiment with the translations, they spotted patterns and were able to verbalise them, and they were able to make conjectures based on their experiments. The students' responses to question 4(ii) on the pre- and post-tests give us cause to believe that the students have also achieved learning goal 2 during the task sequence. Both students gave an incorrect answer in the pre-test but in the post-test both revised their answers. Áine recognized that the statement is true for  $a = 0$  but not otherwise, and used her experiences on Tasks A and B to explain her reasoning. In the pre-test Seán considered one numeric example in order to explain his response to question 4(ii). When Seán completed the post-test question 4(ii) he immediately stated that his original response was incorrect and referred to the vertical and horizontal translations from Tasks A and B. Finally, at the end of the interview, Seán was asked if he considered any of the tasks helped him respond to the post-test questions, and he said:

[Tasks A and B] helped me to see and distinguish the differences in changing the values of  $a$  because I didn't fully grasp what it was in the beginning.

It is clear from the task-based interviews that GeoGebra took away the burden of computation; if we had asked students to draw the graphs of the three pairs of functions in Task A by hand, then it would probably have taken them a long time and they may have made mistakes. The use of the sliders in GeoGebra, allowed the students to watch how the graphs changed as the values of  $a$  changed, and they were then able to spot the pattern and then make a conjecture. Eisenberg and Dreyfus (1994) found that the students involved in their teaching experiment seemed to view function transformations as a sequence of two static states (the initial and final graphs) rather than as a dynamic process. They concluded that this may have been as a result of the graphing software available to them in which there was no means to see the continuous transformation developing before the students' eyes. The advent of dynamic geometry software, such as GeoGebra, means that this is no longer an issue: the

students we interviewed for our study seemed to have developed an understanding of function transformation as a dynamic process.

The use of software like GeoGebra makes visualization more immediate for students and we posit that this can help with engagement. We saw, probably because of the ease of visualization in Tasks A and B, that both students felt comfortable in making a conjecture. This corresponds with Borwein's (2005) description of how mathematicians use technology in their own work, and we suggest that giving students the opportunity to use technology in this manner might encourage them to develop mathematical thinking skills (Mason & Johnston-Wilder, 2004).

Furthermore, in the pre-test Seán seemed to see Q4(ii) as referring to a single function, but in the post-test he immediately recognizes that it is a general statement. We suggest that it is his experience of working on Tasks A and B that accounts for this change in perspective, although it may be that he is recalling earlier understanding rather than developing it during the task sequence. We note that the ability to appreciate the distinction between an instance and a generality is crucial in the development of mathematical thinking (Dreyfus 2002). Seán's response could also be interpreted as a move towards seeing functions as objects rather than simply actions.

Eisenberg and Dreyfus (1994) suggested that students found transformations in the horizontal direction (e.g.  $f(x) \rightarrow f(x + a)$ ) more difficult than those in the vertical direction (e.g.  $f(x) \rightarrow f(x) + a$ ). They contended that one reason for this may simply be that more is involved in visually processing  $f(x+a)$  than  $f(x)+a$ . However, we found no evidence of this in the think-aloud interviews with our students. In fact, the students were quicker to conjecture, and more articulate in their description of, a general relationship between the graphs of  $f(x)$  and  $f(x+a)$  (Task B) than between  $f(x)$  and  $f(x)+a$  (Task A) which we supposed was due to the order in which the tasks were presented.

It may be that our students would have had more difficulties justifying their conjecture in Task B rather than Task A, but such justifications were not part of our task sequence. One might criticize our task sequence as not being cognitively challenging, but we wanted to focus on conjecturing rather than proving. The tasks could easily be modified to allow students to input other functions in order to check their hypothesis, and could be expanded to ask for justifications or proofs.

We agree with Simon and Tzur (2004) that the HLT construct is useful in task design as it highlights the importance of having clear learning goals and an informed view of how learning might take place at all stages of the design process. We feel that it can help when designing new versions of tasks if the original learning goals are not met, and furthermore provides a way of evaluating tasks by comparing the hypothetical learning process with actual learning.

We have found some evidence that conjecturing tasks can encourage students to experiment and explore. We note that Bass (2015) sees this exploration as the first step in most mathematical work, and therefore it is a necessary skill that students should develop to improve their mathematical thinking. With this aim in mind, we hope to continue to design and evaluate tasks of this type.

*Keywords: Task analysis, lesson planning, learning progressions.*

### Introduction

Over the past two decades, there has been significant growth in the number of classification or categorization systems designed to characterize the complexity of tasks used by mathematics teachers during instruction and on assessments. Concurrent with this increase has come an expanded interest in the notion of ‘rich’ tasks. Not surprisingly, the meaning of ‘rich’ task employed, and the system utilized to classify tasks as being ‘rich’ are culturally, politically and institutionally dependent. For example, task-complexity classification systems utilized by teachers in the U.S are typically district- or school-dependent and can vary widely (e.g. Smith & Stein, 1998). Research on learning progressions in mathematics education has increased significantly over this same time period. According to Lobato and Walters, learning progressions “document students’ movement through benchmarks that are predetermined as a result of researchers’ rational analysis of particular content” (2017, p. 75). Therefore, learning progressions can “inform teachers about what to expect from their students . . . [and] provide an empirical basis for choices about when to teach what to whom” (Daro, Mosher, & Corcoran, 2011, p. 12).

In the following sections, we present the *Task Progressions Framework* for use by: (1) teachers as they select, (re-)design, modify, or create mathematical tasks for a lesson or a sequence of lessons; and (2) researchers to analyze the quality, diversity, and complexity of tasks in a lesson or sequence of lessons. The goal of the framework is to support teachers in assembling, and researchers in analyzing, a sequence of tasks that helps students develop or use particular mathematical ideas and associated mathematical habits of mind. The framework allows teachers and researchers to ascertain the focus, coherence, and ‘richness’ of a sequence of tasks comprising a lesson (or lessons). As such, the framework integrates learning progressions and task-complexity classification systems to support instruction that helps students develop grade- or course-appropriate mathematical ideas and habits of mind. This paper seeks to concisely describe the framework, its development, and how researchers might utilize aspects of the framework to address the following research question: How can learning

progressions support analysis of the quality, diversity, and complexity of tasks in a lesson or sequence of lessons?

## Background

Prior to examining the framework's development and anticipated use, it is necessary to first clarify specific terminology that will be utilized throughout the discussion. Such clarification will help make our perspectives explicit. In addition, it will be worthwhile to describe existing criteria and perspectives that served to inform the development of the Task Progressions Framework.

## Mathematical Tasks and Rich Tasks

We employ Umland's (2011, p. 1) definition of a *mathematical task* as a “problem or set of problems that focuses students' attention on a particular mathematical idea and/or provides an opportunity to develop or use a particular mathematical habit of mind . . . [where] *mathematical idea* includes both mathematical concepts and procedures”. Tasks can be further differentiated in terms of their use or purpose, where *teaching* or *instructional tasks* are “designed to support students' mathematical learning or development and *assessment tasks* are designed to evaluate the development of students' mathematical knowledge and/or habits of mind” (Umland, 2011, p. 1). Aligned with Umland's (2011) terminology, we will call the mathematical idea and/or habit of mind that a task is intending to develop or assess, along with its intended use, the *purpose of the task*. We also drew upon a variety of ‘rich’ task criteria to develop the Task Progressions Framework. Grootenboer (2009, p. 697) describes key aspects of rich mathematical tasks to include: academic and intellectual quality; group work; catering for diversity through multiple entry points, multiple solution pathways; connectedness; and multi-representational. For Swan (2005, p. 9), a rich task (a) is accessible and extendable; (b) allows for decision making by the learner; (c) involves testing, explaining, proving, interpreting, and reflecting; (d) promotes communication and discussion; (e) encourages invention and originality; (f) encourages questions that focus on ‘what if’ and ‘what if not’; and (g) is enjoyable and provides an opportunity for surprise.

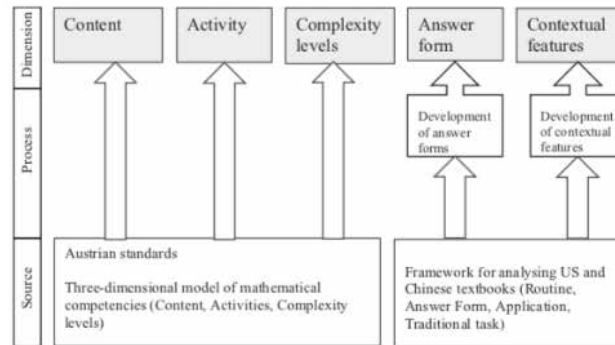

## Learning Progressions

The National Research Council (2007, p. 214) characterize learning progressions as “descriptions of the successively more sophisticated ways of thinking about a topic that can follow one another as [students] learn about and investigate a topic over a broad span of time” (p. 214). For Daro et al. (2011, p. 12) “Learning progressions identify key waypoints along the path in which students' knowledge and skills are likely to grow and develop in [mathematics]”.

## Framework

We employed a networking of theories approach to coordinate and combine theoretical approaches into developing a framework to support teachers' assembly, and researchers' analysis, of tasks grounded on learning progressions. Textbooks have a major influence on teachers' practices and students' mathematics opportunities, because textbooks are considered to be one of the most important and powerful curriculum resources in mathematics education (Fan, Zhu & Miao, 2013). In addition, teachers often re-design or modify textbook problems to meet the mathematical needs of individual students or promote particular mathematical habits of mind. Such activity is a form of

problem-posing on the part of teachers (Rowland, Huckstep, & Thwaites, 2003). We realize that a teacher's capacity to modify or create her own tasks is a function of the education system in which she operates, and countries with national, centralized mathematics curricula offer different affordances and constraints than countries with decentralized curricula. Two existing frameworks were foundational to the development of the Task Progressions Framework—one focusing on textbook tasks (Glasnović Gracin, 2018), the other on teachers' mathematical problem posing (Courtney, Caniglia, & Singh, 2014). Glasnović Gracin (2018) developed a five-dimensional framework to examine the requirements in textbook tasks (Figure 1).

**Figure 1: Five-dimensional framework outline (Glasnović Gracin, 2018, p. 6)**

The five-dimensions are comprised of two distinct theoretical sources (Glasnović Gracin, 2018, p. 6): a three-dimensional model of mathematical competencies (Content, Mathematical Activities, Complexity Levels) based on the Austrian educational standards, and a two-component framework for analysing U.S. and Chinese textbooks involving Answer Forms and Contextual Features. Courtney et al. (2014) developed seven criteria to operationalize the characteristics of rich mathematics problems or tasks. These criteria emerged through meta-analysis of existing research (Table 1). The proposed Task Progressions Framework was developed by incorporating Glasnović Gracin's framework and Courtney et al.'s criteria with research on learning progressions. Several areas of overlap occur between Glasnović Gracin's framework (Figure 1) and Courtney et al.'s criteria (Table 1), including: (1) 'Complexity levels' and Characteristic #1 (High cognitive demand); (2) 'Activities' and Characteristics #3 and #4 (Require justification or explanation; Make connection between two or more representations); and (3) 'Answer form' and Characteristic #5 (Openness).

Rich mathematics problem / task characteristic	Operational criteria
1. High cognitive demand	Problem involves creating, evaluating, and analyzing (comparing) versus remembering or statically using or applying procedures, facts, or skills.
2. Significant content	Problem meets one or more content standard.
3. Require justification or explanation	Problem includes a statement or question specifically asking students to justify or explain their answer.
4. Make connection between two or more representations	Problem incorporates two or more of the following representations: real life, manipulative, pictures, diagrams, or symbols.
5. Open-ended: a) Strategy, b) Solution	Problem includes more than one solution strategy; more than one solution.
6. Allows multiple entry points	Problem allows for a variety of entry points.

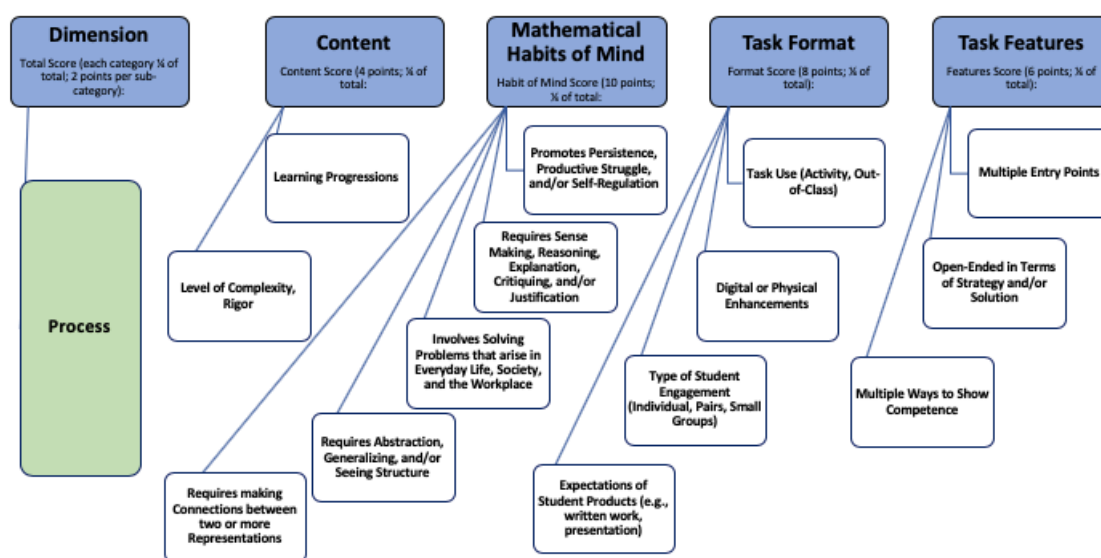

7. Allows multiple ways to show competence	Problem allows for more than one way to show competence (e.g., draw, write, or graph answer); the emphasis is on the product.
--------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------

**Table 1: Operationalized criteria of rich mathematics tasks (Courtney et al., 2014, p. 148)**

The proposed Task Progressions Framework consolidate areas of convergence. In addition, we attempted to allow for the framework's use over both national (i.e. Italy's *Indicazioni*, Japan's *Courses of Study*) and decentralized curricula and various habits of mind classifications (e.g. Cuoco, Goldenberg, & Mark, 1996).

## Task Progressions Framework

The proposed Task Progressions Framework is comprised of four primary categories or dimensions, as illustrated in Figure 2: (1) content, (2) mathematical habits of mind, (3) task format, and (4) task features. Each dimension plays a unique role in the framework, and each sub-category or process (e.g. Type of Student Engagement) is of equal importance within a given dimension (i.e. there is no hierarchy within a dimension). Figure 2 also provides proposed scoring information for researchers attempting to utilize the framework to analyze the quality, diversity, and complexity of tasks in a lesson or sequence of lessons. Finally, each of the four dimensions is given equal weight, regardless of the number of processes or sub-categories.

**Figure 2: Task Progressions Framework**

Content refers to the learning goals for what students should know and be able to do at the end of instruction (e.g. standards). The framework allows for a variety of content to be utilized, such as: Common Core State Standards for Mathematics (NGA Center & CCSSO, 2010) or the National Curriculum Framework Mathematics Area (Ministry of Science, Education and Sports, Republic of Croatia, 2010). Critical to content are the complexity of the knowledge and skills students need to engage productively in the task (i.e. level of complexity or rigor) and where a task's content is situated in a learning progression. The Mathematical Habits of Mind involve the mathematical processes and proficiencies that support students in creating, inventing, conjecturing, and experimenting (Cuoco et al., 1996). The framework addresses habits of mind by requiring teachers to identify where and how

a sequence of tasks: (i) promote persistence, productive struggle, and/or self-regulation; (ii) requires sense making, reasoning, explanation, critiquing, and/or justification; (iii) involves solving problems that arise in everyday life, society, and the workplace; (iv) requires abstraction, generalizing, and/or seeing structure; and (v) requires making connections between two or more representations. Such habits of mind are not isolated and frequently interact and overlap with one another. Task Format identifies the manner in which students are expected to engage with the sequence of tasks (in-class activity, in pairs), how students are expected to illustrate their task products (e.g. presentation) and whether tasks are digitally enhanced or involve physical manipulatives (e.g. algebra tiles). Finally, Task Features involve meeting the needs of all students in the classroom (e.g. differentiated instruction) by requiring the sequence of tasks provide: (a) multiple entry points; (b) multiple ways to show competence; and (c) open-ended strategies and/or solutions. Unfortunately, limitations in space do not allow for a more robust elaboration of the framework and its development.

### Utilizing the Task Progressions Framework

Next, we address the research question by providing an example for how researchers might utilize aspects of the framework, those connected with learning progressions, to analyze a sequence of 8<sup>th</sup> grade mathematics lessons (covering approximately 80 minutes of instruction) involving the Common Core standards (NGA Center & CCSSO, 2010)—used by 42 of 50 U.S. states. The lessons were created by an 8<sup>th</sup> grade math teacher to help his students develop proficiency with the content standard identified by the alphanumeric indicator or code ‘8.EE.8a’ (see Table 2). All tasks used during the lessons derive from the class textbook *Big Ideas Math: Modeling Real Life, Grade 8* (Larson & Boswell, 2018). Due to limitations in space, we focus the discussion on *whether* and *how* the sequence of tasks (sets of problems) address content indicated by considering learning progressions. Standards-based coherence map resources (e.g. Student Achievement Partners, 2013) utilizing learning progressions and our own reflecting on students’ development of successively more sophisticated ways of thinking about systems of linear equations in two variables, identified those content standards with the potential to be taught concurrent with and standards essential as prerequisite to standard 8.EE.8a (see Table 2). In addition, we determined that it was important for students to recall what it means for a linear equation to have a solution, no solution (e.g.  $2x + 3 = 2x + 5$ ), and infinitely many solutions (e.g.  $3x - 4 = 3x - 4$ ), and to interpret the “equation  $y = mx + b$  as defining a linear function, whose graph is a straight line” (NGA Center & CCSSO, 2010, p. 55).

Alphanumeric Indicator / Code	Grade Level / Domain	Standard Statement
8.EE.8.a	8 <sup>th</sup> Grade / Expressions and Equations (EE)	8a - Understand that the solution to a pair of linear equations in two variables corresponds to the point(s) of intersection of their graphs, because the point(s) of intersection satisfy both equations simultaneously.
8.EE.8.b (Concurrent)	8 <sup>th</sup> Grade / Expressions and Equations (EE)	8b - Use graphs to find or estimate the solution to a pair of two simultaneous linear equations in two variables. Equations should include all three solution types: one solution, no solution, and infinitely many solutions. Solve simple cases by inspection.
8.EE.8.c (Concurrent)	8 <sup>th</sup> Grade / Expressions and Equations (EE)	8c - Solve real-world and mathematical problems leading to pairs of linear equations in two variables. (Limit solutions to those that can be expressed by graphing.)

8.EE.6 (Prerequisite)	8 <sup>th</sup> Grade / Expressions and Equations (EE)	6 - Use similar triangles to explain why the slope $m$ is the same between any two distinct points on a non-vertical line in the coordinate plane; derive the equation $y = mx$ for a line through the origin and the equation $y = mx + b$ for a line intercepting the vertical axis at $b$ .
7.EE.4.a (Prerequisite)	7 <sup>th</sup> Grade / Expressions and Equations (EE)	4a - Solve word problems leading to equations of the form $px + q = r$ and $p(x + q) = r$ , where $p$ , $q$ , and $r$ are specific rational numbers. Solve equations of these forms fluently. Compare an algebraic solution to an arithmetic solution, identifying the sequence of the operations used in each approach.
6.EE.5 (Prerequisite)	6 <sup>th</sup> Grade / Expressions and Equations (EE)	5 - Understand solving an equation or inequality as a process of answering a question: which values from a specified set, if any, make the equation or inequality true? Use substitution to determine whether a given number in a specified set makes an equation or inequality true.

**Table 2: Content or Practice associated with standard 8.EE.8.a**

The lessons utilized several tasks or sets of problems as examples or assigned as in-class or out-of-class practice. Regarding prior topics and standards, the teacher assigned four problems as in-class practice (to be worked on in student pairs) from the ‘Review & Refresh’ section of the textbook (see Figure 3). None of these four problems focus on any of the standards 6.EE.5, 7.EE.4a, or 8.EE.6 (see Table 2) identified as important prerequisite content. As such, the teacher is not able, at least through this set of problems, to ascertain whether students have developed necessary prerequisite understandings and skills.

**Review & Refresh****In-Class Practice** (Students work in pairs)

Write an equation in point-slope form of the line that passes through the given point and has the given slope.

- 1)  $(3, -4); m = 1$                       3)  $(1, 0); m = -\frac{1}{4}$

Solve the equation. Check your solution.

- 4)  $\frac{3}{4}c - \frac{1}{4}c + 3 = 7$                       6)  $6x - 3(x + 8) = 9$

**Solve the system by graphing.****Example Problem**

A)  $y = 2x - 2$

$-x + 2y = -4$

11.  $y = 2x + 5$

$y = \frac{1}{2}x - 1$

**Example Problem**

B)  $y = -4x - 7$

$x + y = 2$

**Out-of-Class Practice** (Individual Work)

12.  $x + y = 27$

$y = x + 3$

**In-Class Practice** (Work in pairs)

5.  $x - y = 5$

$-3x + y = -1$

14.  $x - y = 7$

$0.5x + y = 5$

**Figure 3: Practice problems (Larson & Boswell, 2018, p. 201, 203)**

Furthermore, although problems #1 and #3 (Figure 3) focus on ‘point-slope’ form,  $y - y_1 = m(x - x_1)$ , rather than ‘slope-intercept’ form ( $y = mx + b$ ) of the equation, they do provide some sense for interpreting the equation as defining a linear function whose graph is a straight line. Finally, problems #4 and #6 provide practice with linear equations having one solution, but there are no ‘Review & Refresh’ problems involving linear equations with no solution or infinitely many solutions. Therefore, regarding the portion of the framework focusing on ‘Content: Learning Progressions’ (Figure 2), the set of problems demonstrate little in terms of addressing prerequisite understandings and skills.

Several practice problems request that students, “Solve the system by graphing” (Figure 3). Each of these practice problems has a solution, which limits the degree to which interdependent content standard 8.EE.8b (Table 2) is involved. Although none of the practice problems include a real world context, they each require that students “[s]olve ... mathematical problems leading to pairs of linear equations in two variables ... [with] solutions ... that can be expressed by graphing” (NGA Center & CCSSO, 2010, p. 55); thus, partially incorporating content standard 8.EE.8c (Table 2). The last set of problems, utilized by the teacher as an in-class (students work in pairs) and out-of-class (individual

work) assignment, are identified by the textbook as ‘Open-Ended’, ‘Reasoning’, ‘Dig Deeper’, or ‘Problem Solving’ in nature (Figure 4).

**In-Class Assignment** (Students work in pairs)

**OPEN-ENDED**

Write a system of linear equations that fits the description. Use a graph to justify your answer.

22. The solution of the system is a point on the line  $y = -9x + 1$ .

**DIG DEEPER**

24. A graph of a system of two linear equations is shown (at right). Write the system of linear equations represented by the graph. What is the solution of the system?

**REASONING**

26. Is it possible for a system of two linear equations to have multiple solutions? Explain your reasoning.

**Out-of-Class Assignment** (Individual Work)

**PROBLEM SOLVING**

20. A generator contains 60 gallons of fuel and uses 2.5 gallons per hour. A more efficient power generator contains 40 gallons of fuel and uses 1.5 gallons per hour. After how many hours do the generators have the same amount of fuel? Which generator runs longer? Justify your answers.

**OPEN-ENDED**

Write a system of linear equations that fits the description. Use a graph to justify your answer.

23. The solution of the system is  $(3, -1)$ .

**Figure 4: System of linear equation problems (Larson & Boswell, 2018, p. 204)**

Problem #26 asks whether a system of linear equations can have multiple solutions, which intimates at interdependent content standard 8.EE.8b (Table 2) but to a limited degree. Problem #20 includes a real world context, thus incorporating content standard 8.EE.8c into the lesson. Therefore, continuing to focus on the ‘Content: Learning Progressions’ portion of the framework, the set of problems address concurrent understandings and skills to a limited degree. Considering both prerequisite and concurrent content standards in the ‘Learning Progression’ sub-category (Figure 2), we gave the sequence of tasks an overall ‘Learning Progressions’ score of 0.75/2—scoring low on addressing all of the pre-requisite standards (6.EE.5, 7.EE.4a, and 8.EE.6) and concurrent standard 8.EE.8b. Therefore, the complete sequence of tasks would receive a score of 37.5% on the ‘Content: Learning Progressions’ sub-category (or process). Although the remaining dimensions (Mathematical Habits of Mind, Task Format, and Task Features) and the ‘Content: Level of Complexity, Rigor’ sub-category (Figure 2) would need to be addressed to determine the overall quality, diversity, and complexity of the tasks in these lessons, the example presented here provides some indication as to the impact incorporating learning progressions can have on such analysis.

## Conclusion

In this report, we presented a framework for use by: (1) teachers to select, (re-)design, modify, or create mathematical tasks for a lesson or a sequence of lessons; and (2) researchers to analyze the quality, diversity, and complexity of tasks in a lesson or sequence of lessons. The proposed Task Progressions Framework integrates components of existing task analysis frameworks (e.g. Courtney et al., 2014; Glasnović Gracin, 2018), notions of ‘rich’ tasks, task formats, differentiated instruction, and learning progressions to develop a guide for teachers to assemble, and researchers to analyze, a sequence of tasks that help students develop or use particular mathematical ideas and particular mathematical habits of mind. We are currently working with in-service (or practicing) 6<sup>th</sup>-11<sup>th</sup> grade mathematics teachers (students ages 11-18 years) to utilize the framework in their practices with the intent to examine its effectiveness. We anticipate the need for modifications to the framework to make it more practical for teachers (as they create lessons) and researchers (as they analyze lessons).

# Combining Differentiation and Challenge in Mathematics Instruction: A Case from Practice

Seán Delaney and Ann Marie Gurhy

Marino Institute of Education, Ireland; [sean.delaney@mie.ie](mailto:sean.delaney@mie.ie); [annmarie.gurhy@mie.ie](mailto:annmarie.gurhy@mie.ie)

*Despite the challenges of teaching mathematics to diverse learners and the importance of students engaging in cognitively demanding tasks, practice-based research on instruction that combines these priorities is relatively rare. In this paper, a primary mathematics laboratory is used as the setting for implementing such instruction. Records of practice – including video records of teaching, lesson plans, and student work – are analysed to identify task characteristics and teacher actions that supported differentiated instruction and work on challenging tasks. Among the themes identified are the teacher actively guiding the students' learning, the establishment of classroom norms, and enabling all students to act as resources for one another's learning.*

*Keywords: Individualised instruction, Productive struggle, Problem sets, Difficulty level, Teaching methods, Classroom environment.*

## Introduction.

In many countries classrooms are increasingly diverse and teachers need to cater for students from a wide variety of intellectual, linguistic, cultural, social and economic backgrounds. However, relatively few supports are available to help teachers differentiate instruction so that all students, despite their differences, can meaningfully participate in mathematics lessons. Furthermore, using challenging tasks has the potential to improve students' learning (e.g. Stein, Grover and Henningsen, 1996) by engaging students in productive struggle (Warshauer, 2015). One problem is that sometimes in classroom practice only high-achieving students are challenged or differentiated instruction is intended only for some students. Until relatively recently, few studies combined a focus on challenging students mathematically while simultaneously differentiating instruction (e.g. Brown et al., 2017; Lynch et al., 2018; Sullivan et al., 2013). This paper presents a case study of one teacher attempting to engage students in cognitively demanding work over the course of a lesson while simultaneously differentiating instruction.

The following research question is addressed: What steps taken by the teacher supported differentiation and maintained or modified the challenge of the task?

## Theoretical Framework.

Two areas of research inform this study. The first is the mathematical task framework proposed by Stein and Smith (1998) which classifies mathematical tasks into those with lower-level demands (consisting of memorisation tasks and procedures without connections) and higher-level demands (consisting of procedures with connections and doing mathematics). This framework was necessary to identify times when the teacher maintained, raised or lowered the cognitive demand of the task. Although specific tasks may be initially classified using these categories, the classification may change over the course of instruction, as the teacher sets up the task for students and as the task is implemented in the classroom.

Tomlinson's work (2000) on differentiating instruction provides the second pillar of the framework because the teacher's goal is for all students to experience challenge in line with their readiness for it. Tomlinson identifies four elements which teachers can differentiate to meet the needs of all students: content, process, product, learning environment. Content of tasks can be differentiated by presenting information to students in multiple communication modes such as written or oral, or by providing supports to help them read the text. Differentiating the process allows students to complete a task in various ways depending on their preferences; this may involve providing materials, varying the time allocated, permitting individual or group effort, or breaking a task into smaller parts for some students. The product may be differentiated if students are allowed to present their work in multiple ways and to receive credit for diverse skills that are evident in the completed product. Finally, the learning environment may be differentiated by providing quiet space in the classroom for some students, being explicit about how help may be accessed if a student is stuck, and making available culturally familiar support materials to students as necessary.

The twin lenses provided by combining insights from Stein and Smith (1998) and Tomlinson (2000) will help to identify steps taken by the teacher to address both goals of instruction: productive struggle and differentiation.

## **Method.**

### **Context.**

The study is based on a mathematics laboratory that took place over four days (approximately eight hours) in July 2018. The classroom was convened specially to provide mathematics teaching for students, with a focus on differentiated instruction and challenging all students. Furthermore, the laboratory was a site for professional development with over 20 researchers, teachers and teacher educators observing the teaching and subsequently discussing it. Finally, the laboratory was a site for research with extensive records of practice being collected, including video recordings, student work, other classroom artifacts, and teacher planning notes.

### **Participants.**

Twenty-four children – 10 girls and 14 boys – were in the class which lasted for two hours per day over four days. The children had completed fifth class in 11 different schools. Parents and guardians applied for places in the school for their children for multiple reasons, such as their child finding mathematics difficult, their child liking mathematics, or because a friend was attending. In other words, although parents opted to send their child to this class, a wide range of levels of mathematics and motivation could reasonably be expected among those participating.

The teacher has substantial experience as a primary teacher (11 years) and a primary mathematics teacher educator (19 years). He works as a researcher on a project that is focused on mathematics instruction that is differentiated and challenging for students. For several years he has taught children mathematics in a laboratory format as a form of professional development for teachers but this was the first time that the focus was explicitly on differentiation and challenge.

Over the four days of the laboratory, the students worked on four mathematical tasks, each for two hours. One was based on volume, two on fractions, and one, the subject of this paper, on algebra (see Figure 1).

### Data.

Four sources of data were used in this study. First, the task itself, which went through several iterations before being used. Second, the lesson plan that was used as the basis of the lesson. Third, a video recording of the lesson as it was enacted will be analysed. Finally, students' work on the task will be presented.

### Data analysis.

Open coding in which data are scrutinised and concepts identified (Corbin & Strauss, 2008) was used for analysing the four data sources. This involved closely and repeatedly reading the written materials and closely watching and re-watching the video data. The second author identified initial categories and themes, using methods outlined by Corbin and Strauss (2008). Although the coding was open, in that the data were decomposed and concepts were sought and named, the coding complemented a deductive approach to data analysis (Gale et al., 2013) which was informed by the frameworks of Stein & Smith (1998) and Tomlinson (2000).

Alex uses identical tiles to make different sized chair designs for a school art project. The pictures on the sheet show the first three designs created, size 2, size 3 and size 4. Alex wanted a *rule* that would help work out the number of tiles needed for a chair of any size.

Q 1

- (a) If Alex wanted to create a size 5 chair, what would it look like? Can you draw it or use other materials to represent it? How many tiles would be used?
- (b) Work out the number of tiles needed for the size 6 and size 7 chairs. Explain how you did this.
- (c) Draw or make the size 1 chair. How many tiles did you need?

Q 2

- (d) Do you notice any pattern between the chair size and the number of tiles needed each time? Discuss this pattern with your partner(s).

Q 3

- (e) Alex wanted to create a size 20 chair. Talk with your partner(s) about a *rule* that would help Alex work out the number of tiles needed for this chair.
- (f) Would this rule work for the previous chair sizes?
- (g) If yes, write out this *rule* in words.
- (h) Discuss if it would work for a chair of any size.

Q 4

- (i) Could you re-write this rule using symbols/letters?

Q 5

- (j) Use the *rule* to calculate the number of tiles needed for a "size 50" chair?

**Figure 1: Algebra task (without enablers or extensions)**

## Findings.

In terms of the framework/task analysis guide by Stein & Smith (1998), the chosen task is deemed to make “higher level demands” on learners and it has characteristics of both procedures with connections (e.g. use of a table for the first bullet point; writing a rule for the second; getting students to compare solutions for the third) and doing mathematics.

In analysing video recordings of the two hours of teaching, three themes were identified: Teacher actively guiding the students, teacher establishing classroom norms that facilitated differentiation and work on challenging tasks, teacher facilitating students to be resources for each other’s learning. Each of these themes will now be elaborated on in more detail.

### Teacher actively guiding the students.

Six ways in which the teacher actively guided the students were identified by analysing the tasks used, the lesson plans and the video. The first related to the choice of task and planning. Each task was chosen carefully so that all students had the opportunity to make some progress on it and some students could complete it all. For example, the basic algebra task (See Figure 1) was complemented by preliminary “enablers”, for students who struggled to start or make progress on the task and more challenging “extensions”, for students who successfully completed the basic task. One enabler suggested organizing data in a table and another commenced a rule pattern which could be continued. An extender presented for comparison three different methods used by other “students” to find the rule to calculate the number of squares needed for any size chair.

During autonomous work, when two students were working on tasks, clear instructions were issued to students. For example, the teacher suggested that “to make things easier for yourselves, make sure you label the different chairs.”

The teacher deliberately directed students’ attention to particular ideas or concepts. For example, at different times he found ways to introduce the idea of a row, a constant, and a variable. These concepts were introduced in response to comments or confusions from the students and would be help them in working towards a general rule.

The teacher sought opportunities to highlight ideas he believed would support students’ work. As students worked on the task, the teacher asked them to pause their work and he introduced the following idea to support their work:

Just one thing I want to show you. This is just a convention and it might be helpful for some of you. Some of you have already moved on to this step. In algebra, which is what you’re doing now, this is called algebra, this kind of maths. One of the things you do in algebra sometimes is that you use letters as well as numbers so sometimes you might use  $x$  and  $y$ . Sometimes you might use  $a$  and  $b$  or sometimes you might use  $n$ .” (5533 @23:32)

In Lilly’s work (Figure 2), it appears from what she has written that she sees the pattern. However, although she is aware that the letters may be used, she is unable to integrate them into the general solution that she has identified. In contrast, Abby was able to express one general formula that could be used to calculate the number of tiles in a chair, where  $y$  is the size of the chair and  $y \times 3 + 5$

gives the number of tiles (Figure 3). Note that Abby also uses the term “constant” in her written answer.

The teacher questioned students for clarification. For example, using Lilly’s idea of a chair of size 0, he asked “Can anyone explain what Lily has just said or put it into your own words?” (5527@8:40). On another occasion he used revoicing (O’Connor & Michaels, 2007), when he attempted to clarify what a student was saying, “so you’re saying the shape is always the same except for....” (5534@19:12).

The teacher attempted to increase the challenge for students. For example, he asked if anyone could come up with a rule that works for any size chair (video clip 5527, 5:03) and on another occasion he set the following challenge for students: “Now I want everyone to think carefully. How does David’s rule compare with Tim’s rule? (Clip 3527 @ 15:55).

Finally, the teacher’s active guiding of students involved giving them time to think. After posing a question, he allowed students sufficient time to think of an answer before calling on someone to answer.

### **Teacher establishing classroom norms that facilitated differentiation and work on challenging tasks.**

A second theme identified relates to how the teacher established and promoted classroom norms that facilitated differentiation and work on challenging tasks. One such norm that was encouraged was that confusion is okay on the path to learning/understanding. At one point the teacher said “Remember it’s really important to say that you’re confused. Have you followed anything at all of what Tim has said?” (5527@11:05). This followed a contribution from Tim that would lead towards a solution to the task.

Other norms evident in the video include the use of talking about mathematics. Students do not just write their solutions but they are encouraged to share their ideas with their classmates and to have them questioned and critiqued by their peers.

Students are encouraged to take responsibility for their learning. The nature of learning is discussed. For example, students are told that like working out in the gym, learning mathematics requires effort. That doesn’t mean that “maths is difficult” or you are “no good at maths” but that over time, the effort will lead to learning.

Manipulative materials are made available to students (e.g. square tiles) and students are encouraged to use what they need if using the materials will help them grasp the concept. Students are given autonomy in deciding to use or not use the materials.

Finally, students are encouraged to represent their solutions in visual form. In particular, they are encouraged to explain ideas for their parents using representations. This differs from a more common approach in schools where students simply present their solutions in their own notebooks in numerical form.

### Teacher facilitating students to be resources for each other's learning.

The third theme identified from the video data was the teacher's encouragement of students to be resources for one another's learning. At the outset of the summer school the teacher explicitly stated to the students that "you can learn a lot from your classmates." The idea of students being resources for each other's mathematics learning was encouraged throughout the summer school.

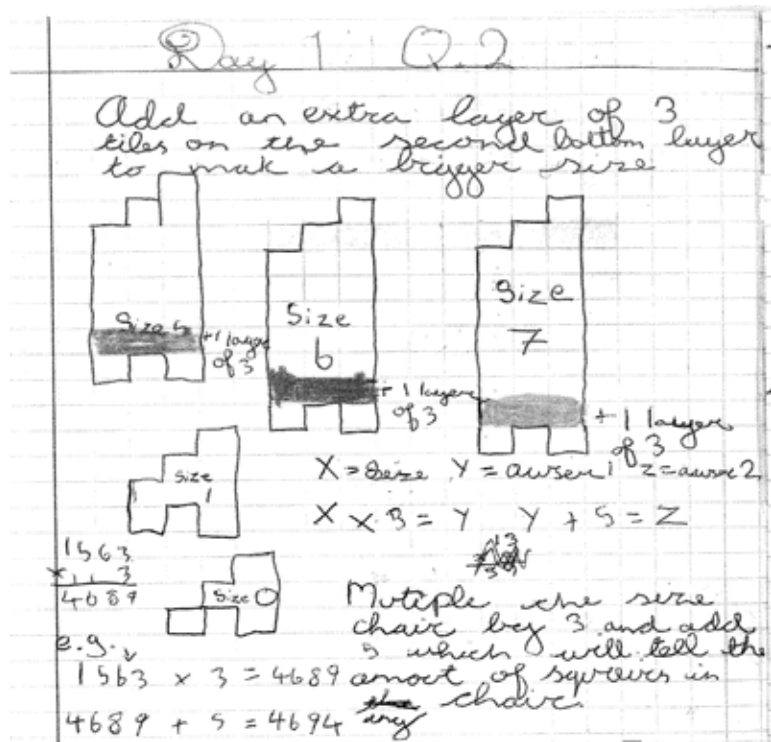

Figure 2: Lilly's work on the algebra problem

One way the teacher did this was to ensure that students or groups of students were given opportunities to share their solutions. Attempts were made to sequence the sharing in a way that progressed from more naïve to more sophisticated solution strategies.

Students' sharing of solutions was complemented by several examples of the teacher asking students to repeat, revoice, or explain what was said. This had the potential to amplify what students said (by hearing them a second time), to clarify what was said (through explanations) and it encouraged students to listen to one another because they realise that they may be asked to respond to another student's input.

Students were required not only to listen to contributions from their classmates; the teacher frequently asked students to analyse and compare different solutions and ideas. This affirms students' solutions but it further has the potential to help them see where some solutions might be more efficient than others.

Finally, students are frequently asked to clarify their ideas or those of their peers by using words and representations. For example, on one occasion when students were working on the task, the

teacher asked a student to “Come up and show us how you laid it out in your notebook” (5527 @9:20).

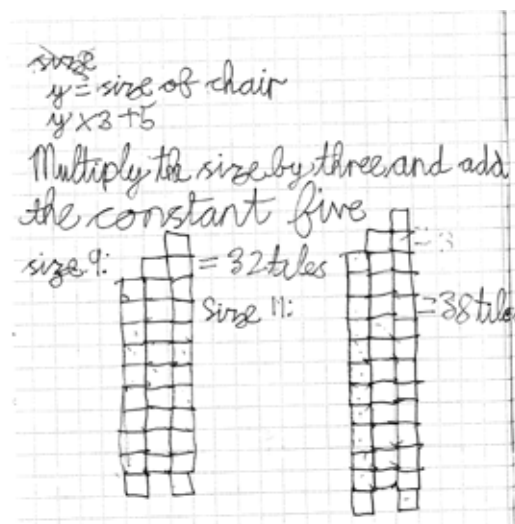

Figure 3: Abby's work on the algebra problem

### Discussion/Conclusion.

We return now to the research question that we posed at the start of this paper about how the teacher supported differentiation and maintained or modified the challenge of the task. Modification of the task was planned in advance through the use of enablers and extenders. In the course of the lesson three themes were identified to capture ways in which the teacher implemented differentiation and cognitive demand. He actively guided the students to take responsibility for working on the task. He established and maintained classroom norms that supported these aims and he encouraged students to act as resources for each other's learning.

What these findings suggest is that through intentional and deliberate actions, a teacher can combine both differentiation and challenge in mathematics instruction. The need for differentiated instruction may be imposed on a teacher by the different rates at which students complete tasks. However, in order to engage students in challenging tasks, teachers must set that as a specific instructional goal and must have the required knowledge to implement it (Henningsen & Stein, 1997). Although the importance of teacher guidance and establishing appropriate norms have been identified as factors in supporting the use of challenging tasks independently, the additional factor of students acting as resources for one another was found to apply when challenge was combined with differentiated instruction.

# Designing tasks with self-explanation prompts

Anneli Dyrvold & Ida Bergvall

Uppsala University; anneli.dyrvold@edu.uu.se; ida.bergvall@edu.uu.se

*This paper presents some results from an ongoing review on self-explanation prompts. An emphasis is laid on design principles based on empirical research. The review is grounded in scaffolding theory, which means that the self-explanation prompts are seen as a temporary support that the student shall learn to manage without. Three themes identified in the review are described and discussed in relation to design and implementation of tasks with self-explanation prompts: prompts with different purposes, the necessity to adapt prompt to students' prior knowledge, and factors of importance for students' engagement in the prompts. Examples of tasks with prompts for which these design aspects have been taken into account are given in the paper.*

*Keywords: Scaffolding, ZPD, reading, multimodal, review.*

## Introduction

In mathematics classrooms, individual and group work on mathematical tasks is a frequent activity. Besides the mathematical complexity of the task, different design aspects also have bearing on students' learning. In this paper, we focus on design aspects concerning *self-explanation prompts* (hereafter SEPs), and how they can be used in tasks or instructions to scaffold students' learning.

The use of SEPs has been investigated in previous studies, often with pre- and post-tests, and some design aspects regarding SEPs have proven to be more effective than others when it comes to students learning (e.g., Berthold, Eysink & Renkl, 2009; Lin, Atkinson, Savenye & Nelson, 2016; Rau, Aleven, & Rummel, 2015). In this study, we utilize a qualitative perspective in order to highlight aspects concerning how tasks or instructions with self-explanation prompts can be successfully designed and used to scaffold students' learning in mathematics in relation to the zone of proximal development (ZPD). The study is based on an ongoing literature review of previous empirical studies on SEPs and their effectiveness. We also take a broad stance and include studies on SEPs in different subjects. A bottom-up perspective is used to search for prominent characteristics in the sample of studies on SEPs. More precisely, the following research question is answered in the current paper: *Which important aspects are there to consider in task design in order to scaffold students' learning in mathematics aided by self-explanation prompts?*

Studies on task design refer to either domain specific or domain transcendent aspects (Thanheiser, 2017). Domain specific aspects concern for example how tasks can be designed to support conceptual understanding. Domain transcendent aspects on the other hand takes a more interdisciplinary stance on, for example, reasoning, life skills, or reading of multimodal texts. In this paper, we focus on domain specific aspects with a focus on pupils' development of conceptual understanding, as well as on domain transcendent aspects, mainly regarding how SEPs can be used to support students' ability to read multimodal mathematical texts. In this study the emphasis is laid on the resources natural language, images, and mathematical notation.

## Scaffolding and self-explanation prompts

Scaffolding is theoretically founded in a socio-cultural tradition. It is a metaphor which illustrates how people are assisted to reach learning goals that would not easily have been reached without scaffolding. In accordance with scaffolding theory, SEPs are meant to support learning in the zone of proximal development (ZPD) and therefore scaffolding needs to be adapted to the pupil and his or her needs and level of understanding. Another aspect of the scaffolding metaphor is that when the building is finished, that is, when the student has developed the targeted knowledge, the scaffolding needs to be removed. Finally, the scaffolding includes a transfer of responsibility from the teacher to the student (Bakker et al., 2015).

Traditionally, scaffolding has been referred to as the interaction between teacher and student, but the term was expanded to also include, for example, artefacts or instruction plans (Bakker et al., 2015). In the present paper, we study SEPs as a particular form of scaffolding of importance for task design.

In several previous studies, self-explanations are described as a successful means to increase students' knowledge and ability to solve problems (e.g., Chi, de Leeuw, Chiu & LaVancher, 1994; Rittle-Johnson, 2006). The self-explanations are explanations of a concept, a relation, or procedure given by the student to him or herself. SEPs has proved especially effective in subject areas such as mathematics and science, which often consist of general principles with few exceptions (Rittle-Johnson & Loehr, 2017). By explaining to oneself, it is possible to reconcile new information and to make inferences to prior knowledge (Chi et al., 1994; Berthold et al., 2009). What gives effect is the process to formulate an explanation, either to oneself or to others. Self-explanations however, are nothing that students usually do spontaneously and therefore prompts to self-explain have a large potential.

## Method

The search for articles for the review has been limited to articles published after 2009. We both searched ERIC, with the search terms *self*, *explain*, and *prompt* and forward tracked selected key papers. Criteria for inclusion was a focus on prompts requesting students to self-explain while working on a typical written task or expository text. The collection of 41 relevant articles was analysed in an iterative process where categories were created and re-created based on what was revealed in the articles. Initially the articles were coded regarding choice of variables, method, and results, with a particular focus on how SEPs were defined and implemented. New categories both emerged and were dismissed based on what was eminent in the articles. The use of this iterative analysis resulted in a few final themes for which rich qualitative data could be derived from several of the analysed studies. Three of these themes are presented in the current paper.

## Results

The answer to the question about which important aspects there are to consider in task design in order to scaffold student's learning in mathematics aided by SEPs is presented in three themes.

### Theme 1: Using prompts for different purposes

Among studies that reveal positive effects of self-explanations, the prompts are used for three different purposes. Firstly, SEPs can scaffold the students in how to process the content and therefore enhance learning concerning domain specific aspects. The most prominent purpose is to encourage

inferences. Inferences are provoked by SEPs including a *why* question (e.g., Roelle & Berthold, 2013; Nokes et al., 2011) or by explicitly requesting arguments (Berthold et al., 2011). The advantage with SEPs that provoke inferences has also been revealed in comparisons with other SEPs (Roelle, Müller, Roelle, & Berthold, 2015; Neubrand & Harms, 2017). Inference prompts are superior for the acquisition of conceptual knowledge. It is evident that the *active* construction of the self-explanation is intrinsic since other prompts given in combination with explanations of the inferences requested by the inference prompts are less beneficial (Roelle et al., 2015).

Secondly, SEPs can be used in a domain transcendent manner to support reading, and therefore enhance learning. SEPs focusing on reading have shown positive effects on learning outcomes when the SEPs are designed to induce focused processing of the text and to avoid shallow reading. For example, SEPs providing reading guidance in terms of higher order questions that require the learner to actively generate inferences about unfamiliar content, have proven to be effective means to develop conceptual knowledge (Roelle & Berthold, 2013). Gap-filling prompts that support reading by prompting the student to make inferences and by that add coherence to the text, also lead to greater learning, as shown by Nokes, Hausmann, VanLehn, and Gershman (2011). Particularly effective are step focused prompts, supporting students in the reading by drawing attention to each step in an example, with prompts to explain, elaborate and summarize (ibid.). Studies that evaluate the use of SEPs in multimodal text reveal different benefits in relation to the use of such prompts. When reading multimodal text, it is intrinsic to understand how the different representations relate and SEPs can successfully facilitate such an understanding. SEPs can scaffold the reading by prompting the reader to relate parts of, and explain relations within the text (Rau et al., 2015) as exemplified in Figure 1.

Figure 1: *Open-ended prompts to make inferences and to relate between modalities*

For example, the student can be prompted to self-explain which perceptual features of graphic representations that depict corresponding concepts and complementary information (Rau et al., 2015).

Such prompts to relate and translate between representations lead to better learning results compared to general prompts to self-explain (e.g. ‘explain your answer’) (van der Meij & de Jong, 2011). SEPs are particularly useful when many representations must be related to deeply understand key concepts (Rau et al., 2015). Figure 1 is an example of how prompts can be used to support reading of multi-modal texts. The first prompt draws attention to how the bars in two different colours represent the two classes mentioned in the text. The second prompt foster attention to the meaning of the axes in the graphic representation and demand the reader to relate information given in natural language and visually. The knowledge of how to read and understand the various parts of the diagram is essential.

Lastly, SEPs can diminish the cognitive load and therefore contribute to the fulfilment of the first two purposes (support reading and processing of the content). If SEPs are designed to guide the attention to relevant principles in a text, extraneous cognitive load can be decreased, and as a result, learning can be improved (Wang & Adesope, 2017). There is however a potential opposite effect; SEPs can increase extraneous cognitive load if they do not suit the reader, for example if the prior knowledge is high and the prompted inferences therefore are perceived as redundant and distracting.

## **Theme 2: Adaptation of prompts to students’ prior knowledge**

The positive outcomes from the work with SEPs is dependent on the match between the student and the prompt. In particular, the students’ prior knowledge is crucial. For example, prompts to make inferences are demanding. Neubrand and Harms (2017), who categorizes inference building prompts as high-knowledge prompts, do however reveal that even for medium knowledge learners the most positive impact with regard to quality of SEPs is created by using a combination of less demanding prompts (paraphrasing, recourse of previously given information, searching for relevant relations between parts of the text) and high demanding prompts (anticipative, inference-building and with recourse to prior knowledge).

In some studies, interventions with SEPs do not lead to better learning outcomes than for the control group. One possible explanation for the lack of effect of SEPs is either that the knowledge level with abstract concepts is too high for the students (Hsu & Tsai, 2013), or that the level is too low and that the prompted self-explanations hinder the students in their work (Roelle & Berthold, 2013). In a socio-cultural perspective, this can be understood as if the concepts are not held within the students’ ZPD. If the new information is at an overly high level, the students will not have the opportunity to make the connections between new information and previous knowledge, which are required for learning. The intended effect of SEPs can also be missing if the level of the concepts or procedures that students should develop is too low. In a study by Neubrand et al., (2016) it appeared that worked examples (WE) with SEPs are effective for students with medium-level of prior knowledge. For students with good knowledge of the subject, WE with SEPs were negative for learning outcomes, no matter how they were designed. SEPs then presents a disadvantage for the students since the previous knowledge and the information given in the WE simply becomes redundant and perhaps boring or distracting. Figure 2 shows a task with different prompt options which can be used for students at different levels of knowledge.

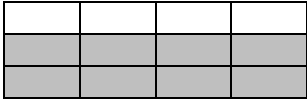

<p>a) Calculate the product of <math>\frac{3}{4}</math> and <math>\frac{2}{3}</math></p> <p>b) The rectangle represents the whole. Use the rectangle to illustrate the product <math>\frac{3}{4} \cdot \frac{2}{3}</math></p>	
<p><u>Prompt version 1</u></p> <p>The grey part of the rectangle represents <math>\frac{2}{3}</math>.          Try to mark <math>\frac{3}{4}</math> of the whole rectangle with dots in such a way that <math>\frac{3}{4}</math> of the grey area are dotted at the same time. The dotted grey area represents <math>\frac{3}{4}</math> of <math>\frac{2}{3}</math> and also the product of the fractions. Why?</p>	<p><u>Prompt version 2</u></p> <p>You know that <math>3 \cdot \frac{2}{3}</math> can be interpreted as taking <math>\frac{2}{3}</math> three times. It is however difficult to imagine taking something <math>\frac{3}{4}</math> times (as in the task). Use your illustration and explain what the multiplier <math>\frac{3}{4}</math> means and how your explanation relates to 3 in the product <math>3 \cdot \frac{2}{3}</math></p>

Figure 2: Task with two versions of self-explanation prompts

The first version of a prompt is intended for students with less prior knowledge. Students who are very unfamiliar with this type of task can also be given a worked example with a starter prompt. Version 1 gives more scaffolding and gives recourse to representations in the task and is therefore adapted to less prior knowledge. Version 2 offers less scaffolding, and encourages the student to use prior knowledge while making inferences and is therefore adapted to medium to high prior knowledge.

### Theme 3: Designing tasks and self-explanation prompts that engage students

A crucial factor in achieving the intended outcome from the use of SEPs is student engagement in the explanations. In several studies (e.g., Hsu & Tsai, 2013) the students' answers to the given SEPs were not sufficiently well processed and the quality was insufficient. However, the results in these studies also showed that students who actually produced well-developed and high-quality responses also showed good results in the post-test. The reasons why students did not engage in the SEPs varied. Pre-formulated self-explanations in a game environment for primary school children is one example of SEPs that was not sufficiently engaging for students to give any effect on learning (Hsu & Tsai, 2013). Another reason for students not to engage actively in the work with SEPs was that the students experienced the SEPs as demanding and simply skipped them (Lin et al., 2016).

Students' lack of engagement in SEPs can also be explained by the extensiveness of the SEPs. In a study by Kapli (2010), no effect on conceptual knowledge or problem solving performance were found if SEPs were given together with supportive instructions. The scaffolding given by the SEPs was however not gradually faded out, rather the scaffolding was continuously accessible for the students. This may have had the effect that students did not take sufficient effort to understand the concepts; instead, they could use the support at any time. However, the study also showed a positive correlation between quality in the students' self-explanations and the acquisition of conceptual knowledge.

Figure 2 is sufficient as an example of design aspects in relation to student engagement, since there is a relation between prior knowledge and student engagement in a task. With prompt options a student can choose no prompt, or prompts adjusted to more or less prior knowledge and to their willingness to engage in deep learning in a particular task. In accordance with theory about scaffolding, students are supposed to learn to manage by themselves what the prompts scaffold and therefore one

optional version of a prompt is not always sufficient. In Figure 1, the student needs to take an active role in constructing the knowledge requested by the SEPs, which might be engaging. If the prompts on the other hand were formulated as multiple choice alternatives the prompts are likely to be less engaging (see e.g., Hsu & Tsai, 2013).

## Discussion

The current paper contributes to previous research on SEPs with a qualitative perspective and a focus on design aspects. The design of tasks with SEPs is done in relation to a target group, but the usefulness of a particular prompt can vary between students in a class and therefore our results is applicable also in relation to the implementation of the prompted tasks. We argue the usefulness of SEPs is dependent on a match between the task, the prompt, and the student. This interrelation is relevant in relation to all three themes presented in the paper.

It is also apparent that the three presented themes are related. Theme 1 about the prompt's purpose is related to both the other themes since the purpose must be taken into account when prior knowledge and students' engagement are considered. Theme 2 and theme 3 are also interrelated since engagement is often dependent on prior knowledge. This means the adaptation to all three themes in design of SEPs could be highly beneficial in providing opportunities for learning, when they are combined and taken into account simultaneously. Figure 3 illustrates how the three themes overlap in a common intersection. According to the results of this study, tasks that can be described as belonging in this intersection, offer the best opportunities for learning.

Figure 3: *Three interrelated themes, appropriate to consider together*

In the everyday practice when using SEPs in mathematics there is several aspects to consider. Firstly, SEPs can scaffold different types of learning and the teacher, or task designer, must know what he or she intends to achieve with SEPs. Students may benefit from SEPs when new concepts are introduced since the SEPs support them in integrating knowledge to what they have learnt previously (e.g., Nokes et al., 2011) and from SEPs that support reading text with different representations of a concept (e.g., Rau et al., 2015).

Secondly, the SEPs must be adapted to students' prior knowledge that is relevant in relation to the content of the mathematics text. Since prior knowledge vary in a group of students we argue for a flexibility in the use of SEPs, both by utilizing variants of SEPs (Figure 2) and by encouraging students to be flexible in the use of SEPs in such a way that they will only be used when needed. As the students develop their understanding, the SEPs need to be taken away since scaffolding shall be seen

as a temporary support when new abilities and knowledge are developed (Bakker et al., 2015). Such an adaptation to the students is important also since redundant SEPs may increase the cognitive load or distract students and accordingly the teacher needs awareness of this.

Thirdly, SEPs are effective only if students engage thoroughly in the self-explanations. As mentioned previously the fit between students' knowledge and the SEPs is crucial if the SEPs shall lead to the intended learning (Neubrand & Harms, 2017) and too demanding or too trivial prompts can reduce students' commitment to the SEPs. SEPs to make inferences are demanding but also very efficient. An implication for teaching is thus that students need to be given the opportunity to practice more demanding self-explanation in classroom. Students may need to practice on how to formulate appropriate answers to these types of prompts, and to get feedback on their answers. In this way, students can understand what is expected and also understand that the answers are important, which can motivate students to work with their answers to make them high quality.

Lastly, when working with SEPs it is important to bear in mind that the scaffolding has to fade out as students' knowledge increase. This can be done in different ways. In teaching materials, scaffolding ought to be used in tasks initiating a new topic or concept and in such occasions the scaffolding fills a function, for example, in supporting reading of multimodal texts. As the teaching proceeds and the students improve their ability to read multimodal text, the scaffolding become superfluous. It is also possible for the teacher to take an active role in the use of scaffolding, by carefully following the development of the students' knowledge in order to use SEPs only to students considered in need for this support. To conclude, we see a large potential in the use of SEPs but the design of prompts and the adjustments to the student group is a delicate task to achieve the intended learning.

<sup>2</sup>Örebro University, School of Science and Technology, Örebro, Sweden; [per.nilsson@oru.se](mailto:per.nilsson@oru.se)

*Mathematics education is still behind in the implementation of digital technology. Digital technology can support classroom talk, but this potential needs to be further explored. This study reports on a project that develops and explores task design principles, through a series of interventions, that are intended to utilize digital technology to enrich mathematics lessons. The results consist of three design principles together with their theoretical and empirical arguments from analysis of a lesson series about pattern generalization. The three principles exploit opportunities provided by technology to make reasoning available for examination to all students, and to focus students' attention between different aspects of mathematical reasoning.*

*Keywords: Math-talk, design principle, digital technology.*

Digital technology has been recognized for its potential for teaching and learning mathematics. Task designs relying on digital technology offer students amplified opportunities to explore, re-invent and explain mathematical concepts using tools imbedded in technology-rich environments (Leung, 2011). However, Lagrange and Monaghan (2009) argue that digital technology adds to the complexity of teaching mathematics. It challenges traditional teaching practices by creating new classroom situations and possibilities (Drijvers, Doorman, Boon, Reed, & Gravemeijer, 2010). Pierce and Ball (2009) argue that teachers need to make it their own, and relate technology rich lessons to their usual practice. We propose that one way forward is to take a modest approach, to digitally enriching mathematics classroom talk by using material from actual teaching practices and show how to enhance these practices with the use of digital technology; i.e. to create designs that shift between a digital and an analogue environment within the mathematics classroom. However, the research on uses of digital technology to enrich and support classroom talk is in its infancy and needs more exploration (Mercer, Hennessy, & Warwick, 2017).

Design principles are thought of as guidelines for task design (Bakker, 2018) that can inform on how to recreate learning opportunities in other classrooms than the intervention ones. The aim of the present paper is to propose task design principles for developing a digitally enriched math-talk learning community (Hufferd-Ackles, 2004), focused on algebraic reasoning. The research question we attempt to answer is: *what are important task design principles for a technology enriched pattern task to gain potential for math-talk?*

### Theoretical background

Students act upon mathematical objects on the basis of their assigned meaning of that object, and their interpretation of others' actions towards those objects (Blumer, 1986). As the students and the teacher interact with each other, and the tasks, they negotiate the mathematical content and create a joint interpretation of that content. For example, in a pattern task: a student suggests an algebraic

expression to represent the number sequence behind the pattern, and the teacher asks for a clarification on the student's reasoning in relation to the pattern. Such expressions can be created through the use of visual structure reasoning (Rivera, 2010). Students can reason with visual structure units of  $n$  in visual patterns as a tool for writing an algebraic expression. Figure 1 shows an example of color coding to highlight visual structure units. With this particular partition, red is  $n$  and blue is  $n+1$ , forming the expression  $n+(n+1)+n$ . Such tasks open up for student interaction to negotiate both how to partition a visual pattern in visual structure units, and how to formulate the expression, creating a math-talk learning community.

**Figure 1: The pattern task**

A Math-talk learning community is “a classroom community in which the teacher and students use discourse to support the mathematical learning of all participants” (Hufferd-Ackles, Fuson, & Sherin, 2004, p. 82). It is a learning community where students are encouraged to negotiate meaning and gain some responsibility for the mathematics forming in the classroom. The teacher should strive to shift the responsibility of the questioning and the source of the mathematical ideas from the teacher to the students (Hufferd-Ackles et al., 2004). The students are encouraged and supported to take an active role, focusing on mathematical thinking and reasoning rather than waiting to answer leading questions from the teacher, to create investigative discussions in mathematics. Digital technology has the potential to amplify students' opportunities to explore, re-invent and explain mathematical concepts in such practice (Leung, 2011), which we believe enriches their Math-talk learning community.

To understand the complexity of classroom practices with human/machine interaction, Trouche (2004) introduced the idea of instrumental orchestration. The idea is that teachers create opportunities for students to negotiate mathematical meaning by organizing available artefacts, i.e. didactical configuration (DC), and determining how to utilize these artefacts, i.e. exploitation mode, combined with the ad hoc decisions made by the teacher in the classroom, i.e. didactical performance (Drijvers et al., 2010). A DC including a projector offers the possibility to make a student's visual structure reasoning public and available for all students to interpret and react upon. When the projection is directed at a (interactive) whiteboard it also allows the teacher to exploit the possibility to allow students to indicate and manipulate digitally and analogous what is projected in a collaborative effort to negotiate meaning and develop students' reasoning (e.g. Taylor, Harlow, & Forret, 2010).

Task design combines elements of the DC with ways of exploiting that configuration in line with the teachers intended learning goal. A task design for research interventions relies on implicit or explicit design principles that are intended to produce favorable classroom situations. Van den Akker (2013) suggests the following elements of a design principle:

- *If you want to design intervention X [for purpose/function Y in context Z]*
- *Then you are best advised to give that intervention the characteristics C1, C2, ..., Cm* [Substantive emphasis]
- *And to do that via procedures P1, P2,...,Pn* [methodological emphasis]
- *Because of theoretical arguments T1, T2,...,Tp*
- *And empirical arguments E1, E2,...,Eq*

(Van den Akker, 2013, p. 67)

It could be viewed as an expansion/formalization of the ‘didactical’ questions *what?*, *how?* and *why?* to form a design principle. The *what?* is connected to the characteristics of the intervention, a purpose of a design. The *how?* is connected to the procedures in the intervention, how a teacher should act, how a task is meant to be used, and so on. The *why?* is motivated by both theoretical arguments based on prospective analysis of prior research and teaching/learning theories, and empirical arguments where the design principles are fine-tuned by prior teaching experiences and experiences from the ongoing intervention (Van den Akker, 2013). Design principles are heuristic principles that cannot guarantee success, but they are intended to select and apply the most appropriate knowledge for specific task designs.

The previous research and theory resulted in two hypotheses connected to a potential lesson design:

- Didactical configurations with technology can be exploited to make students’ mathematical reasoning more accessible for other students to probe and develop during math-talk
- Didactical configurations with technology can be exploited to turn students’ attention to different aspects of a mathematical content and reasoning

## Method

The project this paper reports on follows a design research approach as it aims to develop a research-based intervention, and construct re-usable design principles in an iterative manner (Bakker, 2018). A prototype of a lesson plan makes up a hypothetical learning trajectory (HLT) grounded in research (Simon, 1995), and is tested and refined several times. The HLT consists of the learning goal, the activity and the intended development of the students. During this iterative process, we generate data by video recording from three different angles, back of the class, front of the class and group work. Each lesson is tried and refined twice before moving on to the next lesson.

The research team consists of two elementary mathematics teachers, working with year 7 and 8, and two researchers, the authors of this paper. The project is a cooperative enterprise where we perform prospective analysis of the tasks, develops the task design, analyze the material and make changes together. Each design decision is motivated through theoretical and empirical arguments. The recorded material is used for reflective analysis between each lesson where we discuss what, how and why in different situations during each lesson and retrospective analysis of the whole lesson series after completion. Situations are evaluated regarding how digital technology enriches teacher-student and student-student interaction, especially in relation to opportunities for math talk and opportunities for students to seize initiative in the discussions. Parts of the reflective analysis is presented in the results below to reveal empirical arguments for the design principles.

## Design

Lesson 1, in its initial form, aimed to develop the students’ proficiency to reason in line with different types of algebraic reasoning with visual structures. Specially to challenge naïve additive reasoning and suggest a more advanced strategy, i.e. multiplication of units, by asking them to reason about different ways of identifying visual structure units in the visual pattern. The students were given

questions and tasks individually and in pairs through Socrative<sup>1</sup>. Figure 1 shows one of the tasks with color coded visual structure units, where the students were asked to identify an algebraic expression that fitted the coloring. The students were presented with the task through Socrative and given the following alternatives: a)  $2n+2+2$  b)  $n+(n+1)+n$  c)  $n+1+n+n$  d)  $4n+1+1$  e) none of the above. The answers were made available to both teacher and students, which was intended to make the students' reasoning available and create an opportunity for whole class discussion where they could question each other's reasoning.

Lesson 2, in its initial form, aimed to develop the students' proficiency to recognize visual templates and characteristics of patterns. In particular to recognize characteristics that make some patterns more difficult to generalize algebraically than others. The students were asked to create their own patterns in pairs and publish them on an online platform called Padlet<sup>2</sup>. Next step for the students was to try to write algebraic expressions for each other's patterns. The lesson ended with a whole class discussion on which patterns were difficult to write expressions for, which were easy, and why? Padlet was intended to make each pattern accessible to each student, and easily swappable in group work as well as in the whole class discussion.

Lesson 3, in its initial form, aimed to develop the students' problem-solving proficiency and flexible reasoning. Particularly to transform patterns and use visual structure reasoning as a tool to generate algebraic expressions of more complex patterns that are not representations of standard arithmetic sequences. Figure 2 shows the initial 4 figures of the Hexagonal pattern that the students were asked to generalize. The students worked in pairs with tasks distributed through Socrative, and the main task was in a geogebra applet. The applet enabled the students to try ideas by moving and grouping the dots in each figure effortlessly, and negotiate different strategies with each other's. Our goal was that the students would recognize a possible visual template from a quadratic pattern ( $n^2$ ) in the previous lesson by creating rectangles with  $n$  dots on one side and  $2n-1$  dots on the other (figure 3). The whole class discussion was intended to focus on different visual structures and resulting algebraic expressions by visualizing the pattern transformation in the applet on the projector.

Figure 3: The Hexagonal pattern rearranged

## Results

This section presents the results of the prospective analysis, and a retrospective analysis of selected episodes. We propose three design principles, that we present empirical and theoretical arguments for throughout the result section. The first principle is a development of our first hypothesis, going into the design process, and the second and third principles are a development of our second hypothesis:

<sup>1</sup> Socrative is an online response system where teachers post questions that show up on students' devices and allows them to post answers. Answers becomes instantly available for the teacher, and for the students too if the teacher wishes.

<sup>2</sup> Padlet is an online virtual pinboard that allows students to publish pictures and other types of contributions. Contributions becomes instantly available for the whole class on each device.

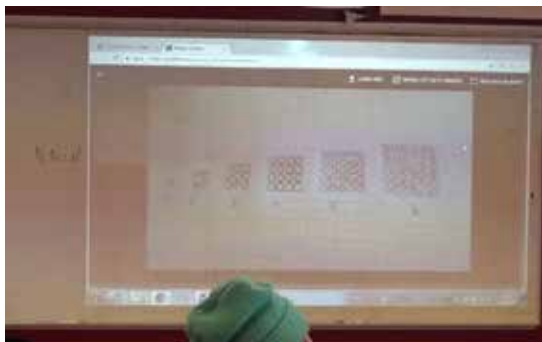

1. Exploit the possibility to project mathematical reasoning on students' devices or on the white-board (WB) with the classroom projector.
2. Exploit the possibility to indicate and/or manipulate objects projected on the WB collaboratively
3. Exploit the possibility to switch between individual/small group work and whole class discussion by focusing the students' attention to their own devices and the WB respectively.

Each episode presented below is from the first iteration of each lesson. The situations motivated changes in the task design and provides empirical arguments to refine the design principles. The first transcript is from Lesson 1, where the students have been engaged with task 4 “If I say ‘tell me how many dots are in figure  $n$ ’, what do you think I mean?” with the alternatives a) That you’ve mistyped b) That the last figure is called  $n$  c) That you mean a figure, anyone in the sequence d) That  $n$  means a number, any number e) Don’t know. All, but one, chose either c) or d) or both.

Teacher: Two of the alternatives works. That you mean a figure, anyone in the sequence, that it could have been figure number 9 or number 1000 or number 2000000 and so on. [...] We move on.

The teacher immediately starts to summarize the results since almost everyone chose the correct alternatives. Our interpretation was that the task did not reveal much about the students' interpretations of  $n$ , or allowed them to make indications to develop their reasoning together with the class, prompting the teacher's action. We interpret the shortcomings as related to characteristics and procedures of the first two design principles. When the question is open, the students need to be able to answer more freely than with multiple choice. In relation to the second design principle, we revised the task on a procedural level, adding teacher prompts and offered whiteboard markers that encourage students to make their reasoning available both with their written answer and by approaching the board to indicate and explain in the picture. The result was a discussion where students got the opportunity to explore each other's interpretations, since they became more explicit.

Next example is from Lesson 2, where the students have written algebraic expressions to each other's patterns while working in pairs. Figure 4-6 shows the teacher going back and forward between two examples with different students accounting for their reasoning. The teacher encourages the students to apply the same visual structure reasoning in both cases. Notice how figure 2 and 3 both have some sort of visual structures indicated by color-coding or circles. The figures are in chronological order.

**Figure 4:** A student presented an algebraic expression for the square pattern task without

**Figure 5:** Two students presenting their generalization by using visual structures

Figure 4 shows the board right after a student has presented her solution, written on the left ( $n^2$ ). Figure 5 shows how two students present their solution, with the aid of visual structures drawn in the pattern faintly with a yellow and a red marker. The teacher then exploits the possibility to flip back to the previous pattern and asks the students to use a similar strategy to expand on their reasoning in the quadratic pattern. The students focus on their own devices, and discuss in pairs before another round of whole class discussion. Students identified visual structures of  $n$  in multiple places in each figure. The negotiation results in the indication in square number 5, where a student has identified  $n$  both vertically and horizontally. It lead to the idea of multiplying base by height. The quadratic pattern was deemed harder than the other ones. By exploiting design principle number 3, to be able to switch students' focus between different tasks, small group and whole class, the teacher managed to create circumstances where the students could develop each other ideas and negotiate a solution that more than one student fully understood.

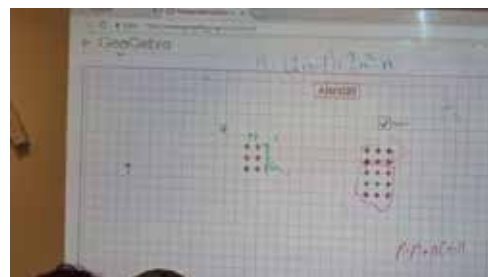

**Figure 6: Several students have identified visual structures in the square pattern task**

The third example is from Lesson 3, where the students were asked to write an expression for the hexagonal pattern shown in figure 2. The students transformed the pattern into rectangles shown in Figure 7 and 8. Two students present their visual structure reasoning by indicating on the board. Especially notice how the expressions in figure 8 corresponds with their visual structures respectively.

**Figure 7: A student's use of visual structures to justify its reasoning**

**Figure 8: Students connect visual structures to their formulation of an algebraic expression**

Prior to figure 7, students negotiated the best transformation of the hexagonal pattern. A student adjusted the pattern as the discussion progressed, making his interpretation of the discussion available on the board. They agreed on the rectangle, compatible with the base by height reasoning from the square pattern, and continued working on in pairs. This shift back and forth between whole class and group work provided opportunities for students to prepare to assume responsibility for creating the mathematical content in the math-talk learning community. Figure 8 shows two different types of visual structure reasoning. Looking at figure 7, the student explained the “-1” by manipulating the figure further, drawing in a fourth row that is then subtracted. She made her reasoning available to interpret, question and expand upon. In figure 8 we connect the resulting expression above with her visual structures and the *base multiplied by height* reasoning from the previous lesson. Similarly, we connect the second student's visual structure with his algebraic expression. However, he split his figure in two, identifying the square as  $n \times n$  and the small rectangle as  $n(n-1)$  by circling them.

To summarize, our first design principle is to exploit the possibility to project elements of mathematical reasoning directly on students' devices or with the classroom projector. The theoretical

argument is that as the teacher's and student's actions becomes available and interpreted by the class, it adds to the negotiation of mathematical properties and processes connected to the pattern task. The two main empirical arguments connected to this principle are 1) Tasks that does not allow room for individual expression of mathematical reasoning, tends to result in situations where the teacher assumes responsibility for the explanations. 2) When students were able to project their reasoning as a math-talk progressed, as in the discussion leading up to the transformation in figure 7, they reach consensus while assuming responsibility for the process.

Our second design principle is to exploit the possibility to indicate and/or manipulate objects projected on the board collaboratively. The theoretical argument is that the teacher and students can exploit the technology to further explore, justify and explain their reasoning, for example their visual structure reasoning, when incorrect or half-way ready solutions are introduced as collaborative endeavors. The empirical argument is that switching seamlessly between the analogue and digital allowed students to expand on each other's ideas, as seen in figures 4-6. By indicating directly on the board, the students used the projection and the indications together to justify their reasoning in the moment. Student work seen in Figure 7 adds to the argument, the student manipulates the pattern further by adding dots to justify elements of the algebraic expression in the ongoing math talk.

Our third design principle is to exploit the possibility to switch between individual/small group work and whole class discussion by focusing the students' attention to their own devices and the projection respectively. The theoretical argument is that students need time to formulate their arguments to become able to take more responsibility for the questioning and the source of the mathematical ideas in the math-talk learning community. The two main empirical arguments connected to this principle are 1) Switching between small group work and whole class discussion, as seen in the prior work to figure 4-6, students were able to prepare their mathematical reasoning with identical pictures on their own device as later used in the whole class discussion. Enabling them to present advanced mathematical reasoning based on numerical patterns and visual structures of patterns as part of a whole class discussion. 2) By switching focus between the whole class and small groups, as seen in the work leading up to figures 7 and 8, encouraged individual work expanding on the whole class discussions and resulting in multiple solutions to an advanced algebraic generalization task.

## Discussion

The aim of this paper has been to propose task design principles for developing digitally enriched math-talk learning communities, and add to the research discourse on technology supported whole class discussions (Mercer et al., 2017). We propose three design principles, developed on the basis of empirical and theoretical arguments (Van den Akker, 2013). The principles were shown to support math-talk where students collectively were active in negotiating meanings of mathematical objects, rather than waiting for a teacher to provide explanations, corresponding to higher level of math-talk (Hufferd-Ackles et al., 2004). Pierce and Ball (2009) argues that teachers need to be able to relate technology rich lessons to their usual practice. By formulating characteristics of the three principles in a way that they utilize didactical configurations found in many classrooms today, such as projectors, and exploiting the possibility to combine projection with traditional practices, such as writing on the board, we simplify the implementation of a technology enriched mathematics lessons.

Van den Akker (2013) suggests we view these design principles as heuristics. Design principles should not be seen as a guarantee for success (Van den Akker, 2013), but likely producing opportunities for, in this case, rich math-talk. But that is not all they do, experiences from using curriculum materials creates learning opportunities for teachers (Davis & Krajcik, 2005). An actual lesson, created by tasks based on the design principles, is an opportunity to develop ones' capacity to orchestrate lessons that foster math-talk learning communities. Curricular resources are tools to enable teacher learning and to influence teaching practices (Cobb & Jackson, 2012; Davis & Krajcik, 2005). We propose that our design principles could be used in teacher training and collegial learning to discuss how to enrich mathematics lessons with digital technology on a general level. Creating concrete tasks and task design principles is perhaps a step towards a modern mathematics education that takes advantage of what digital technology has to offer to enrich mathematics teaching.

*Our research was carried out in the framework of the MC2 European project (<http://www.mc2-project.eu/>, 2013-2016) aiming at developing a socio-technical environment for the design of digital resources fostering creative mathematical thinking. Through a network of theories, we conceptualise and study social creativity that occurs during collaborative design of a digital resource embedding mathematics into a story. We focus on factors that trigger, or hinder social creativity and that influenced a group of designers, made up of mathematics teachers, teacher educators and researchers with diverse expertise, broadening perspectives, supported by a socio-technical environment during the design process.*

*Keywords: Process of collaborative design, social creativity, digital resource.*

## Introduction

Our research is motivated by promoting creativity in teachers and students, collaborative work and the use of digital artefacts to solve real world or interdisciplinary problems, and considering mathematics teachers as designers (Kynigos & Kolovou, 2018). It was carried out in the framework of the MC2 European project (<http://www.mc2-project.eu/>, 2013-2016) aiming at developing a socio-technical environment facilitating and enhancing the design of digital resources, called c-books (c for creative), and fostering students' creative mathematical thinking. The technical part of the environment consisted of the so called C-book technology embedding an authoring tool and a collaborative tool called CoIcode<sup>1</sup>. Four communities of designers established in four partner countries, France, Greece, Spain and United Kingdom, constituted the social part of the environment. The French community, on which the paper focuses, brought together educational designers from diverse mathematical fields with manifold expertise and knowledge (researchers, teachers, software designers, etc.) because the process of designing purposeful mathematical activities in multi-representational technical environment is complex. An aspect of this complexity comes from the interrelated processes of learning to purposefully use a new technology, of designing tasks for students to initiate purposeful mathematical activity, of collating the various artefacts for the activity, of supporting students to learn to use technology, and of articulating the teacher's role in supporting the students to navigate their respective routes through the various artefacts to include interaction with the technology (Clark-Wilson & Timotheus, 2013, p. 48). In this paper, we aim at highlighting factors that foster or hinder social creativity (SC) in the collaborative design of c-books. Studying

---

<sup>1</sup> CoIcode is a communication environment part of the C-book technology, offering a workspace within which members of a community engaged in a c-book design can collaborate.

these complex design processes required several theoretical perspectives leading us to network theories and concepts. We start by explaining our theoretical framework and the conceptualisation of social creativity. We pursue by refining our research questions and by exposing our methodology before presenting an analysis of one case study. We conclude with some salient results.

## Theoretical framework

Collaborative design of creative digital educational resources within a socio-technical environment is a complex human activity intertwining manifold interactions and elements which are difficult to capture without any relevant lenses.

As a first lens, within the activity theory (AT), Engeström (1987)'s model of activity structure (Figure 1) helps us focus on particular elements, called entities, that intervene in the design activity: *subject* that is the group of designers, *object* that is the c-book being designed, *community* with which the designers' group interacts, mostly the designers of the C-book technology, *rules* that govern the design process, *division of labour* that occurs among the designers, *tools and signs*, such as *artefacts* used by the designers, mostly the C-book technology including the CoI Code collaborative workspace, and *outcome* that is the designed resource, as well as learning that can occur during the design process. Engeström (1987)'s model highlights also interactions between these entities, which allows to describe and understand the context of the design process.

**Figure 1. The structure of an activity system (Engeström, 1987, p. 78)**

Engeström (2001) expands his model and sheds light and awareness on the interactions occurring between different individual activity systems, i. e., when the *subject* is a single designer. It is illustrated by the minimal structure of two interacting individual activity systems (ibid.) which allows to bring to the fore the modifications of the *object*. The *object* moves from an initial state of un-reflected, situationally given “raw material” (*object 1*) to a collectively meaningful object constructed by the activity system (*object 2*), and to a potentially shared or jointly constructed object (*object 3*). However, the models do not allow us to understand the nature of the entities. In order to capture the nature of the *subject* and *community* entities, we draw on the concepts of *community of practice* (CoP) (Wenger, 1998) and *community of interest* (CoI) (Fischer, 2001). Besides, the designers belong to various “worlds” according to their domains of expertise. These worlds have boundaries that “can be seen as a socio-cultural difference leading to discontinuity in action or interaction” (Akkerman & Bakker, 2011, p. 133). It is therefore important, while studying collaborative resource design, to pay particular attention to what happens on those boundaries. The boundary crossing approach (BC) (ibid.) enables to enlighten the weight of boundaries in the creative design process and the arising

mechanisms of *identification*, *coordination*, *reflection* and *transformation* through the concepts of *boundary object* (Star & Griesemer, 1989) and *broker*, bound to interactions between *subject* – *community* – (*artefact* or *object* or *outcome*), or between two or more individual activity systems. Finally, in order to highlight the role of the teachers (*subjects*) involved in the design, their personal resources (*artefacts*) brought into play in the design, and the trajectory of the digital resource being designed, i.e. its different versions from *mother resources* to *daughter resource* (Hammoud, 2012) (from *object* to *outcome*), we draw on the documentary approach to didactics (DAD) (Gueudet & Trouche, 2009). To sum up, the AT was our main framework allowing to connect all others through the entities of the Engeström's activity system model. Based on this, we have been able to conceptualise our understanding of social creativity.

As a matter of fact, different types of creativity are reported in literature. We have chosen the *little-c* creativity (Craft, 2000), which is when a person realizes a new or improved way to approach an issue or accomplish a task. We draw also on the *componential* tradition of creativity assessment (Hennessey and Amabile 1999) to assess it and on the concept of communities of interest (CoI) for characterising our communities of designers. Thus, within the MC2 project, we define social creativity (SC) as the *generation of ideas* which: (a) stem from a combination of two or more individual *activity systems*, (b) result from various interactions among the CoI members, the C-book technology and tools, (c) are externalized in and through specific digital artefacts (including the *c-books*), and (d) are considered by the CoI members to be *novel*, *appropriate* and *usable* (Daskolia, 2015). Moreover, creativity, social or individual, can be modelled through phases of *divergent* (novel ideas) and *convergent* thinking (appropriate and usable ideas) (Csikszentmihalyi 1996) constituting a *creativity cycle*. Social creativity is characterised by the reification of creative ideas collectively elaborated, i.e. elaborated by at least two CoI members.

## Research questions

In this paper, we address the following research questions: in the collaborative digital resource design activity,

- what interactions between *rules*, *community* and *division of labour* promote or hinder SC?
- what types of objects have the potential to become *boundary objects*, under which conditions and how can they stimulate SC?
- which members have the potential to become *brokers*, under what conditions and what is their role in stimulating SC?

## Methodology

Our methodology relies on one case study, i.e., we analyse the collaborative design of one particular c-book within the French CoI. The data was mostly collected via CoIcode that keeps traces of interactions in the form of ideas posted by each designer (Figure 3), but also through minutes of manifold meetings, exchanged emails and the designed c-books. Although the methodology comprises quantitative and qualitative methods, in this paper we only focus on the qualitative analyses aiming at getting a deeper insight into social creativity processes. The data analysis was processed in two phases. First, we use the AT to describe in detail the design activity context through the activity system entities in order to situate and understand the collaborative design context of the group of

designers. Second, we use our network of theories to qualitatively analyse data and bring to the fore factors impacting the social creativity taking place among the designers.

### A snippet of the collaborative design of the c-book ‘Ski’

In this section, we analyse a few episodes of the collaborative design process of a c-book on ski touring. From the AT perspective, the *object* of the design process was to create meaningful mathematical activities linked to the risks of provoking an avalanche while practicing ski touring to foster students’ mathematical learning and creativity (purposeful activities). The group of designers (*subject*, Figure 2) was composed of seven members of the French CoI (*community*), all closely related to mathematics education with knowledge on mathematics, technology and pedagogy, and sharing a constructivist background.

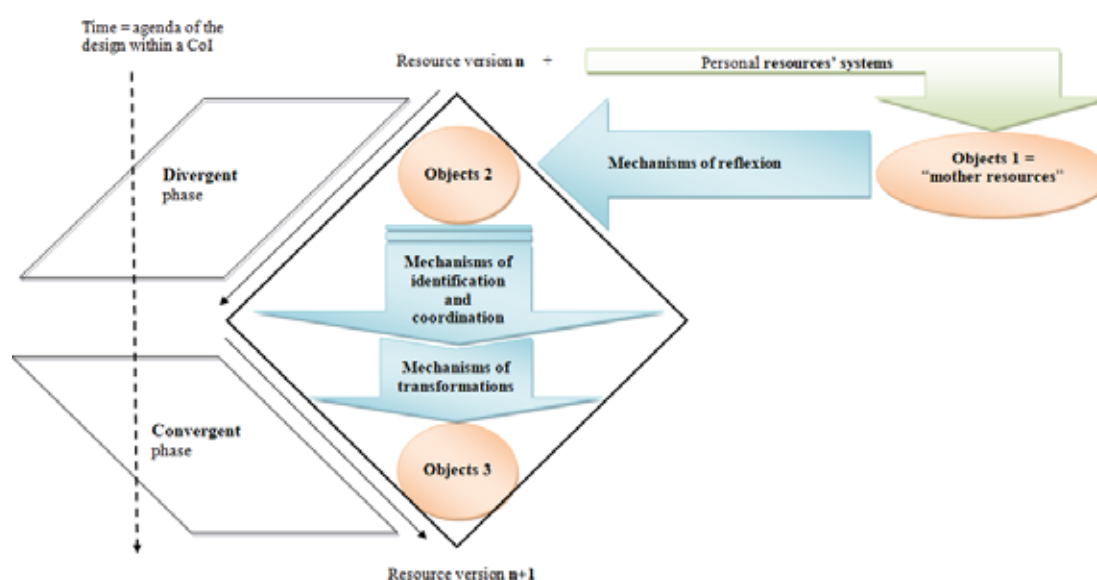

**Figure 2: The designers of the c-book ‘ski touring’**

Four members acted as the main designers: Nina (secondary mathematics and physics teacher and PhD student, with a good knowledge of the C-book technology (*artefacts*)) who moderated the group, Marie (researcher and mathematics teacher educator, expert in mathematical modelling), Fred (mathematics teacher educator, interested in real problems), and Jane (mathematics teacher educator, interested in digital technology in mathematics education) who played the role of a reviewer. The other three members, Marc (expert of digital technology such as dynamic geometry systems), Jean and Adam intervened on request or during CoI meetings (*division of labour*). The main designers’ group was constituted in a way that at least one of them was at ease with digital technologies and especially with the C-book technology (*rules*). The designed c-book (*outcome*) should be used by a teacher of an associated CoP, called MPS, which Marie belongs to (*rules*). This CoP reflects on the use of mathematics for solving interdisciplinary problems with Grade 10 students.

In order to bring to the fore the trajectory of the c-book design process through its versions, we combined documental approach to didactics, activity theory, social creativity and boundary crossing approach. We could identify four versions of the c-book. The initial version was constituted by Marie’s personal resources on the theme of avalanche and skiing (*mother resources = objet 1*), as she has already worked on this topic within the MPS CoP and experimented some activities with Grade 10 students. From her numerous resources, Marie selected several that she instrumentalised through CoIcode posts (*object 2*) (*reflection mechanism = perspective making*). Then, a divergence phase was initiated by a brainstorming amongst the CoI members. It generated nine new directions on real situations and mathematical notions (*reflection mechanism = perspective making*) and some creative ideas, i.e. judged novel, appropriate and usable by the designers. The creative ideas were related to real situations such as the avalanche risk depending on a slope leading to considering angles, the measurement of the angle of a snowy slope with ski poles that requires knowledge of

trigonometry, the shape of snow crystals leading to working on geometric figures, transformations and sequences. This phase was followed by a phase of convergence (*identification, coordination and transformation mechanisms*) characterised by the collective elaboration of some of these ideas with, for instance, some artefacts already known within the French CoI, such as GeoGebra or Cinderella, in order to simulate an avalanche to encourage students to make conjectures about the risks, or programming an avalanche victim search device in order to make students understand the notion of algorithm (*objects 3*). The two phases constituted a creativity cycle. They led to the second version of the c-book pictured through a defined structure and content based on the preparation of a ski tour as a guideline for the story that would guarantee a unity for the c-book. In the following creativity cycle, the creative ideas were mainly bound to the technology and designers' technical knowledge, such as suggesting guidelines how to use GeoGebra for creating snowflakes, devising relevant feedback for students in different ways to enrich the *milieu* of the c-book activities by using widgets that were not familiar within the French CoI, or considering the copy/paste possibilities inside the Chat tool to enable interactions between students or between the students and the teacher (social aspects). During the third creativity cycle, the main concern of the designers was the usability of the c-book by the teachers and students from Grade 10 to 12. The designers were also concerned by giving a unity between all the activities thanks to a story on ski touring and avalanche risk. Hence, the focus of the designers changed from one cycle to the other. In addition, we noticed that a divergent phase was often initiated by a review of the c-book version at stake by the reviewer or by a critical feedback from some CoI members, less involved in the design, during a meeting (*reflection mechanism*). Each version was the result of a creativity cycle, i.e., a divergent phase followed by a convergent one as modelled in Figure 3.

**Figure 3: Model of versioning of the c-book collaborative design process (Essonner, 2018)**

Furthermore, we observed that the first creativity cycle generated ten creative ideas out of 14 ideas judged as creatives by the designers, which was more than in the other cycles. The analysis of this cycle highlights a positive effect of the compulsory use of CoI Code (*rules*) during brainstorming amongst the designers. This was not the case in the other cycles where the designers used also other

media to communicate and to record their interactions, such as emails or minutes from the diverse meetings. Indeed, when the CoI members used CoIcode, they had to read the ideas of the others and to react on them. Each post in CoIcode obliged a designer to reflect on his/her own ideas. The latter had to choose if the idea was new or rather a reaction to another one, and what kind of reaction (opposition, contribution or alternative). Such a structured reflexion turned out to boost SC.

Finally, in order to have a deeper understanding of SC we studied the path of a creative idea, i.e. its collective elaboration. The creative idea we analysed (circled with red in Figure 4) was chosen because of its strong collective elaboration. This idea was preceded by Marie's suggestion to create an activity on algorithms bound to the search of a victim of an avalanche (*mother resource*). Then, Fred's creative idea proposed to work on algorithm with the "GeoGebra turtle". Fred was referring to explicit algorithm (*reflection mechanism*). This suggestion sparked the negotiations between Marc and Fred who expressed different perspectives of a widget around the idea of a "turtle" to model an avalanche victim research device. Marc understood and proposed a widget designed by the Greek CoI using logo language. But Fred did not know this widget. He knew another widget using Java Logo language, which could enable to create explicit algorithm but he was hesitating. Thus, they seemed to share a common frame of reference around turtle and logo, which enabled them to understand each other. The word "turtle" became a *boundary object* between them.

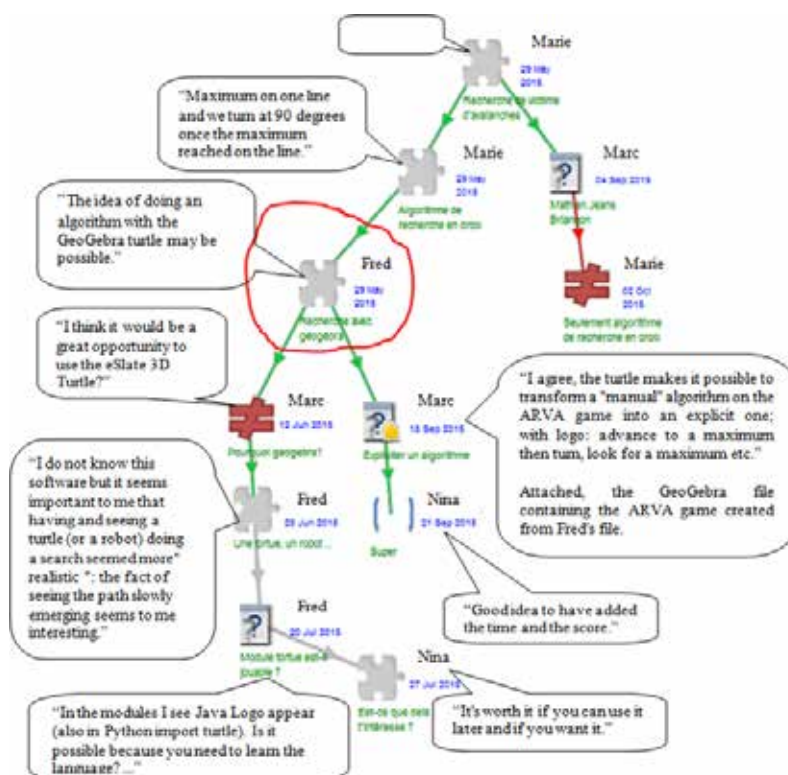

Figure 4: Extract of the CoIcode workspace dedicated to the c-book 'Ski'

Nevertheless, from the meetings' minutes, Nina the moderator found that Fred was in trouble because he could not manage to finalize his widget with GeoGebra (*creative idea*) that should allow students to work implicitly on algorithms. Hence, Nina asked Marc to help Fred. She identified difficulties (*identification mechanism*), and to overcome them, she solicited another member of the CoI

(*coordination mechanism*). Marc, expert of GeoGebra, designed the widget, limited the time and added a score to foster affective aspects (*transformation mechanism = hybridization*, daughter resource). Moreover, Marc was eager to create an explicit algorithm with a widget designed within the Greek CoI, but he did not master the logo language required for working with the latter. He therefore asked the technological expert from the Greek CoI how to write the algorithm and he eventually created a new widget (*transformation mechanism = hybridization*, daughter resource). He thus played a role of *broker* looking for knowledge in another CoI (*community*).

## Conclusion

The analysis of the process of design of the c-book “ski” shows that some *rules* impacted positively social creativity among the c-book designers. One of such rules applies to the constitution of the designers’ community that should be as diversified as possible. The diversity should be understood in terms of complementary expertise of its members (pedagogical, mathematical and especially technical) broadening the discussion meaning, but also in terms of roles to be assigned (moderator, designer and reviewer, *division of labour*). Indeed, the reviewer fostered a divergent phase and the moderator facilitated a convergent phase, supporting *creativity cycle*. In addition, the use of CoIcode to communicate during brainstorming seemed also to enhance SC.

In addition, we noticed that some words (e.g., turtle) allowed the designers to propose various ideas in different perspectives from other contexts, from other cultures. Such words became *boundary objects* widening the CoI perspective. Therefore, within a CoI that designs c-books, we can say that potential *boundary objects* are *malleable*, *transformable* objects, *compatible* with the *object* of the design and belonging to the designers’ common frame of reference. *Boundary objects* helped to extend the common frame of reference between the designers (*coordination*) by enlarging their perspectives.

We found that the *brokers*, who were members of the CoI, were able to identify the missing knowledge for the c-book design, to look for it and then, to share this new knowledge within the French CoI. Thus, in our context, we can say that a *broker* is a member of the CoI who identifies missing knowledge within the CoI, then can find it in another related professional world in order to bring it to the CoI. Thus, the *broker* acts as a coordination mechanism allowing the CoI members to extend their common frame of reference with new knowledge.

## **Building bridges between school mathematics and workplace mathematics**

Rune Herheim and Suela Kacerja

Western Norway University of Applied Sciences, Norway; [rher@hvl.no](mailto:rher@hvl.no), [skac@hvl.no](mailto:skac@hvl.no)

*In this paper, we investigate three examples from two articles written by lower-secondary students in which they identify school mathematics used in workplaces. Their articles are written as part of a project aiming to help students find mathematics relevant. The students provide documentation on advanced use of graphs, mean values, calculations, and formulas in two occupations, music management and physiotherapy. By using Evans' (1999) approach to transfer, we identify similarities and differences between school mathematics and workplace mathematics. In line with Evans' approach, we aim at building bridges between school mathematics and workplace mathematics.*

*Keywords: Workplace mathematics, school mathematics, building bridges, transfer, relevance.*

### **Introduction**

When doing research and following up student teachers in school practice, we hear students say “maths has nothing to do with my life”, “I don’t need maths”, and “maths is something we do in school”. These statements are in line with Masingila’s (2002, p. 37) study in which a majority of the students “think mathematics is synonymous with school mathematics”. Wager (2012, p. 10) built on this by saying that students often do not see “the connection between the mathematics in which they engage in school and the mathematics they experience out-of-school”. The national curriculum in Norway and other countries, e.g. the US common core state standards, specify that students should be able to apply the mathematics learnt in school to the workplace. However, as English (2010, p. 36) argued, “we need further knowledge on why students have difficulties in applying the mathematical concepts and abilities ... outside of school”.

When doing mathematics in school, students often ask “why do I have to learn this?” (Hernandez-Martinez & Vos, 2018, p. 245) or “when will I use this?” (Willoughby, 2017, p. 877). Answers like “you are going to have mathematics next year as well, you know” and “because we have a test coming up” (cf. Onion, 2004), do not address the core of the questions. On the contrary, they might explain the student statements in the first paragraph. Alrø, Skovsmose, and Valero (2009, p. 15) asked eighth grade students what they used mathematics for outside school, and the most frequent answer was “to do homework”. If the only purpose of learning mathematics is to do homework or to be prepared for future teaching and tests, then it is easy to understand from such circular reasoning why students question the relevance of mathematics. Hernandez-Martinez and Vos (2018) argued that students need answers regarding how, why, where, and what mathematics will be relevant because it is so closely related to their motivation to learn and to what extent they see the usefulness of what they learn. Hernandez-Martinez and Vos see usefulness as a property of the mathematics being learnt, and relevance as the potential connection between the mathematics learnt, its usefulness, and the student.

It might seem odd that mathematics, a field of knowledge so vital for today’s society, has difficulties being regarded as relevant. However, being able to give qualified answers regarding the relevance of mathematics involves detailed knowledge of the mathematics required to perform an occupation. One

cannot expect teachers to investigate a range of different workplaces in order to always have an answer when students question the relevance of a mathematical topic. Gaining insight into what extent the mathematics learnt in school is relevant to life outside school is a challenge for teachers and educators, like FitzSimons and Boistrup (2017) and Nicol (2002) found in their studies. This relevance challenge and the importance of connecting ideas and building on students' out-of-school experiences and understanding when working with mathematics in school, constitute the rationale behind the *Workplace mathematics project* referred to in this paper. About 60 lower-secondary students, three of their teachers, and a researcher (the first author of this paper) investigated what mathematics their parents/guardians needed in order to perform their work. The students then wrote articles about their findings with the help from their teachers and in collaboration with the researcher.

By investigating two of the student articles, this paper addresses the following research question: *What school mathematics are the students able to identify in the workplaces?* The analysis focuses on identifying and discussing similarities and differences between mathematics at school and at workplaces and provide a foundation for discussing potential transfer and relevance of school mathematics. We do this by presenting and extending the mathematics the students identified in two workplaces, music management and physiotherapy.

## **Theoretical perspectives and previous research**

In the following, we clarify how the national curriculum links school mathematics with the working life and give a brief overview of perspectives and terms for out-of-school mathematics. We elaborate on the concept of workplace mathematics and on the gaps and potential transfer between school mathematics and workplace mathematics.

### **Links between school mathematics and working life in the national curriculum**

In the Norwegian mathematics curriculum, mathematical competence is considered important for understanding and influencing what happens in society and for “pursuing further education and for participation in working life and recreational activities” (Ministry of Education and Research, 2010, p. 2). Problem solving and modelling are emphasised, and rich experiences with mathematics are regarded as an important foundation for lifelong learning. In addition, the ability to work with mathematical concepts, methods, and strategies to solve problems also “involves learning to pinpoint and describe situations where mathematics is involved” (p. 5). This is defined as an important part of mathematical competence. Thus, being able to identify the use of mathematics is considered as vital for strong mathematical competence in the national curriculum. The workplaces investigated in the project serve as rich contexts for identifying and making sense of the mathematics used.

### **Perspectives and terms for out-of-school mathematics**

There are multiple perspectives and terms in mathematics education research regarding the contextualization of school mathematics and links between school mathematics and out-of-school experiences. *Realistic mathematics* is used to focus on creating meaningful and realistic situations in which students can learn mathematics (Freudenthal, 1991). *Genuine* or *authentic mathematics* concerns real-life situations brought into the mathematics classroom, strongly, but not necessarily, linked to mathematical modelling (e.g. Palm, 2008). *Everyday mathematics* focuses on identifying

everyday situations where mathematics is used (e.g. Nunes, Schliemann, & Carraher, 1993; Masingila, 2002). *Workplace mathematics* is used by researchers who study the mathematical knowledge and skills required to do certain work processes (e.g. Hoyles, Wolf, Molyneux-Hodgson, & Kent, 2002; Wake & Williams, 2001; Wedege, 2006). The perspectives presented have a key aspect in common – they study the potential links between school mathematics and out-of-school mathematics. The project presented in this paper takes the workplace mathematics perspective.

### **Workplace mathematics and transfer**

In UK, two groups of researchers have investigated mathematics in workplaces from different points of view. Hoyles et al. (2002) studied seven different workplaces focusing on the mathematical knowledge and skills required of the employees and identified several mathematical skills as important in different occupations. Wake and Williams (2001) identified general mathematical competences applied in many occupations that also could be incorporated in the mathematics curriculum. Summarized, the competences and skills identified by the two groups of researchers were using proportions and percentages, handling data, using graphs, diagrams, and other tools and interpret them, modelling and solving problems, calculating and using formulas, recognizing anomalous phenomena, and doing extrapolations.

On the other hand, there are also hindrances for identifying the use of mathematics outside school. Workplace mathematics is situated and has to be combined with knowledge about the work to perform required tasks (Hoyles et al., 2002). It can be hidden caused by automation of processes and division of labour, and the nature of school mathematics can cause challenges as well (Williams & Wake, 2007). There are several differences between school and workplace mathematics that can hinder students recognizing mathematics in workplaces, Wedege (2006) argued. She identified seven categories that describe a gap several adults had experienced between workplace mathematics and school mathematics. The differences start at the number level. In the workplace, numbers have units of measurement, calculations have to be constructed, and there are often multiple solutions. In school, numbers often occur without units, the numbers as well as calculations are given, and there is only one correct solution. Solving tasks in the workplace requires collaboration and dealing with disturbing factors, it offers opportunities to use mathematics, and solutions have consequences. Solving tasks in school is often individual work without disturbing factors, and real-life contexts are used merely to create a need for using mathematics and solutions have therefore no practical consequences.

However, the hindrances are surmountable. Wake (2013, p. 315) proposed a new mathematics curriculum to overcome the challenge of transfer “by placing the study of how mathematics models reality at the core of the curriculum”. This curriculum should give students the possibility to make sense of, and develop further, the models of others. Wake considered the research done in workplace mathematics as rich initial contexts to be used by teachers who support inquiry in the classroom. Evans (1999, p. 23), when writing about transfer between mathematics in school and everyday life, linked relevance with transfer by arguing that “if schooling is to be relevant ... we need some account of how learning from the school can be ... ‘transferred’, to other contexts”. He emphasised the importance of building bridges for transfer between school and out-of-school activities by identifying fruitful overlapping and inter-relations, and by analysing similarities and differences.

## Method

### The background for the students articles: the Workplace mathematics project

The project was a collaboration among the teachers, the students, the students' parents/guardians, and the researcher. The teachers contacted the researcher because they wanted to do a project that could help their students see the relevance of mathematics. The teachers' idea of visiting parents/guardians' workplaces to document the use of mathematics was embraced by the students, and more than twenty parents/guardians attended an information/kick-off meeting. The parents/guardians were excited by the idea, they expressed a positive attitude towards mathematics, and agreed to be visited and interviewed. The meeting tuned them into the project and was important in order to go beyond Hoyles, Noss, Kent, and Bakker's (2013) finding that visible workplace mathematics tends to be fragmented, routine-based, and mostly simple calculations.

The students were trained to interview, document, and do pre-investigations by the researcher and the teachers. They were encouraged to gather information about the occupation, the particular workplace, and the interviewee's duties, and identify concrete examples of mathematics being used. The students were grouped in pairs and triads, they decided their approach and interview questions, and then they interviewed, observed, and collected documents and photos. One of the teachers or the researcher joined most of the groups. Many of the parents/guardians had prepared information and examples when the students came. In 2017, after working with data handling, collecting supplementary data, and editing articles according to feedback from the teachers, the researcher, and the parents/guardians, the first student articles were published in a national journal for mathematics teaching. The researcher finished the articles, extended some of the examples, and added reflections on links between the students' examples and the competency aims in the national curriculum.

### Analytical approach

Evans' (1999) approach to transfer, in terms of similarities and differences, is used as analytical lens to investigate what school mathematics the students were able to identify in the work done by the physiotherapist and the music management duo. The identification of similarities are discussed according to the skills identified by Hoyles et al. (2002) and Wake and Williams (2001), and the identification of differences are discussed according to Wedege (2006). These similarities and differences are used to shed light on a potential transfer of mathematics between school and workplaces. The examples in this paper are chosen because they are interesting and contain mathematical details that make it possible to identify links to school mathematics.

### Description and analysis of workplace examples from students' articles

We now present three examples and discuss the mathematics involved. The first two examples come from a music management duo (Tronstad, Graff, & Herheim, 2017). They work with several artists, and one of their main tasks is to help artists make a living of music. An essential question concerns deciding where artists should sell their music: streaming, CD, or both? Figure 1, made by the researcher based on information collected by the students, shows the sales in Norway for CDs and streaming. In 2011, the graphs intersected, and streamed music generated for the first time more money than CDs. The CD sales continued to drop, but in 2014, there seems to be a trend change.

To make a qualified decision on this requires critical reflections based on mathematical understanding by the music managers. In line with Hoyles et al. (2002) and Wake and Williams' (2001) findings, they have to handle data, understand and interpret a graph, and understand the point of intersection of the two curves in terms of income. They have to predict a trend and make a decision based on past data – typical tasks within predictive modelling. Based on these reflections, they can make knowledge-based decisions of where to sell their artist's music. However, in line with Wedege's (2006) findings on differences between mathematics in school and in workplaces, this workplace example includes disturbing factors and the use of measurement units. Furthermore, it actually requires use of mathematics, and it is a decision that has potentially huge economic consequences.

**Figure 1: The sales in Norway for CDs (graph I) and streaming (graph II) in million NOK**

Another aspect is the income generated from having a song played on the radio. In one of the radio channels in Norway, artists earn 60 NOK/minute. If a song lasts three minutes and 23 seconds, you get the following calculation:  $3 \times 60 + (23/60) \times 60 = 203$  NOK. If the song is played 200 times/month, it provides an income of  $200 \times 203 = 40600$  NOK. This resembles common calculations in school. However, there are also several differences. The managers have to find many of the numbers themselves, set up an expression including fractions, calculate it correctly in order to know the potential profit, manage different measurement units such as seconds and minutes in the same formula, and deal with practical unit rates such as NOK/minute and times/month. Again, there is an extensive use of measurement units. To summarize, in these two examples, the music managers have to apply all the competences and skills on Hoyles et al. and Wake and Williams' list. In addition, they need to gain an overview of these elements as parts of a complex system where several factors can influence their decisions such as where to sell the music, marketing, and arranging tours.

The third example comes from a physiotherapist's work with elderly and their walking ability (Berrefjord, Haugland, Nilssen, & Herheim, 2018). When a patient walks across a mat with sensors connected to a computer, a range of functional walking data is registered. The students identified a need for the physiotherapist to integrate mathematics and ICT skills as Hoyles et al. (2002) did. One issue is walking variability, arrhythmic or twitchy walk, and in order to investigate this one needs step times in seconds (see table 1):

Step no.	1	2	3	4	5	6	7	8	9	10	Mean	SD
Left	0,8		0,79		0,8		0,83		0,88		0,82	0,033
Right		0,86		0,82		0,81		0,81		0,77	0,81	0,029

**Table 1: Step times**

Collecting the ten step times in seconds, five for each foot, makes it possible to calculate the mean values and standard deviations (the physiotherapist and the researcher calculated the standard deviation because this is not part of the students' curriculum):

$$\bar{x} = \frac{0,8 + 0,79 + 0,8 + 0,83 + 0,88}{5} = \frac{4,1}{5} = 0,82$$

$$s = \sqrt{\frac{(x - \bar{x})^2}{5}} = \sqrt{\frac{(0,8 - 0,82)^2 + (0,79 - 0,82)^2 + (0,8 - 0,82)^2 + (0,83 - 0,82)^2 + (0,88 - 0,82)^2}{5}}$$

$$= \sqrt{0,0011} = 0,033$$

This example shows the need for dealing with decimal numbers, for setting up formulas and calculate correctly, for systematizing and presenting data, and for using statistical concepts such as mean and standard deviation. Standard deviation is frequently used by researchers to quantify the amount of variation of a set of data. Here, it gives the physiotherapist vital information about the extent to which a person's walk is unstable and influences how the physiotherapist should proceed with the physical treatment. Such use of standard deviation exemplifies that mathematics has practical and concrete consequences. The importance of correctly knowing and using mathematics becomes more visible for the students, and can help them find answers to their relevance questions.

## Discussion and concluding comments

Building bridges between school mathematics and workplace mathematics, helping students see the relevance of mathematics as something more than just being able to do homework and prepare for tests, is a challenge documented by several researchers (e.g. Alrø et al., 2009; Onion, 2004). Students struggle to see connections between school mathematics and out of school mathematic (Hoyle et al., 2002; Nicol, 2002; Wager, 2012; Williams & Wake, 2007), and they find it difficult to apply mathematics outside school (e.g. English, 2010). Teachers have difficulties answering questions from students on why they "have to learn this" and when they will ever need it (Hernandez-Martinez & Vos, 2018). A possible remedy is to include genuine real life tasks, e.g. tasks situated in workplace contexts, as resources more often in the mathematics curriculum. This is one way of overcoming the differences between workplace mathematics and school mathematics identified by Wedege (2006).

In contrast to the above-mentioned challenges, the Workplace Mathematics project generated multiple examples of how school mathematics is necessary in several workplaces, e.g. the use of tables, graphs, units, mean values, calculations, and formulas. This is emphasised by the national curriculum as important for developing mathematical competence. Connections between school mathematics and its usefulness in real life were documented, including information about what kind of mathematics was used, where and how it was used, in addition to why it was needed in the workplaces.

By searching for similarities, the students also identified differences between school and workplace mathematics. The workplace tasks were more complex, had numerous units of measurement, there were several potential useful methods and not one definitive answer, and finally yet importantly, doing mathematics wrong could have severe consequences. Although Wedege argued that such differences can create a gap between school and workplace mathematics, they can also help students

develop a more flexible, nuanced view on mathematics. Identifying similarities and differences makes it possible to build bridges between school mathematics and workplace mathematics, as Evans (1999) suggested, and through this explicate the relevance of school mathematics.

The parents/guardians took part in a kick-off meeting, they were enthusiastic, and several of them were prepared when the students came. This was important for the documentation of numerous examples on how school mathematics is used in different workplaces. The students experienced that school mathematics was used and had practical consequences. Such outcomes can be used to positively influence students in viewing mathematics as relevant, and this constitutes a valuable contribution to their learning and motivation for school mathematics (Hernandez & Vos, 2018). Including links between school and workplaces in the mathematics curriculum can provide fruitful, joint reference points for students and teachers when doing tasks and make working with mathematics more meaningful. Furthermore, the examples can be used to build bridges between school and workplace mathematics by discussing e.g. the importance of choosing appropriate representations for mathematical concepts in a specific situation and moving flexibly between different representations. We therefore argue that engaging students to identify workplace mathematics is worthwhile. However, further research is needed to find ways to help students “explore how mathematics can be transformed to meet the needs of a range of diverse situations” (Wake, 2013, p. 315).

# Task design with a focus on conceptual and creative challenges

Jonas Jäder

Dalarna University and Umeå University, Sweden; [jjd@du.se](mailto:jjd@du.se)

*Tasks are an important part of the education in mathematics. In an ongoing study, an analytic framework for identifying challenges in students mathematical task solving has been developed, and the conceptual and the creative challenge has been defined. Preliminary results indicate that considerations are needed to include these challenges in mathematical tasks. This paper takes off from there to describe a structure for selection and (re)design of tasks. The aim is to be able to discuss the basis for the structure. A further aim is to develop a support for teachers, test designers, textbook authors and others, in creating tasks with specific learning goals.*

*Keywords: Task design, challenges, mathematical concept.*

## Introduction

Tasks are a central aspect of the teaching and learning of mathematics. They may offer students an opportunity to learn and to gain understanding. One way of defining understanding is to manage different mathematical tasks and thereby also overcome obstacles (Sierpinska, 1994). Sriraman, Haavold and Lee (2013) however describe the concept of task difficulty as hard to define and to operationalize. One way of gaining insight into this may be to regard a task as possibly including different types of difficulties, with unique definitions. This also supports the idea of having clear intentions of what learning goals may be reached by solving a task, and to include criterion for success in line with these goals as important aspects of teaching (Brousseau, 1997; Brousseau & Warfield, 2014; Simon, 1995). The opportunities to learn depends on the design of the task and the cumulative effect of certain kinds of tasks is important to consider (Stein & Lane, 1996). Different learning goals imply the use of different kinds of tasks. The definition of two challenges, the conceptual and the creative challenge has, in an ongoing study, been developed from Lithner (2017), and an analytic framework has been developed to be able to identify and characterize these challenges. With a better understanding of tasks, their solutions, and the challenges included, a nuanced discussion of students' opportunities to learn is in focus. Central to the study has been to make it possible to make a distinction between the two challenges. However, the results also indicate that the two challenges exist together and possibly also interplay. One of the important ideas of the framework is that discrepancy between students prior understanding and experiences and what a task requires them to do, is what creates a challenge. Earlier research has indicated that students benefit from working on tasks where they are challenged to go beyond using routine procedures (Jonsson et al., 2014), solving mathematical problems, and struggling with mathematical ideas (Hiebert & Grouws, 2007). However, unfortunately, students in their task solving often use imitative approaches rather than deal with challenges (Sidenvall, Lithner, Jäder, 2015). Preliminary results from the ongoing study indicate that the sum of challenges, conceptual and creative ones, affects students' approach to the task solving. The students in the study, when overcoming conceptual challenges also overcame creative ones. There are however tasks with creative challenges, but no conceptual challenges.

This paper therefore, and supported by the framework and definitions previously developed, suggests a task design structure to include conceptual challenges to a greater extent in tasks, and specifically mathematical problems.

## **Background**

### **Tasks used as artifacts in the teaching and learning of mathematics**

A task in this paper is seen as an exercise intended to support the students' learning (Halldén, Scheja & Haglund, 2008). There is a clear distinction between mathematical problem solving, and other work on mathematical tasks, where a problem is a task to which the individual has no obvious method for solution (Schoenfeld, 1985). In contrast to mathematical problems, are tasks of routine character where the solution method is available to the solver as she identifies the type of question and what is a suitable, corresponding solution method. The use of mathematical tasks in the teaching and learning of mathematics highlights the relationship between task, student, teacher and the subject matter, mathematics. In this paper, the focus is on the design of the task. Brousseau (1997) suggests the arrangement of didactical learning situations, where students get to connect with specific mathematical ideas according to the learning goals of the task. The teacher, for a while, delegates the responsibility of taking actions on the task, to the student. So, the teacher acts on the student through an activity, in this case a mathematical task. It has been shown that a textbook and its tasks is important when teachers structure their teaching (Mullis, Martin, Foy, & Arora, 2012). It seems like a common way of approaching the textbook and its tasks, at least in a Swedish context, is by working from the beginning of each chapter and finish up when time has run out (Sidenvall et al., 2015). However, this may lead to students meeting few challenging tasks (Jäder, Lithner & Sidenvall, 2015). Simon and Tzur (2004) describe a relation between an activity, and the effects of performing the activity, to explain how thoughtfully designed tasks can contribute to the development of a student's conceptual understanding. To actively address specific learning goals, the selection, evaluation and possibly redesign of tasks is important.

### **Conceptual challenges**

Mathematical concepts can be regarded as cognitive objects with different pieces of information attached to them. An ongoing encapsulation develops an elaborated picture of the concept within a person (Tall & Vinner, 1981). Conceptual understanding can be defined as the relationship between different pieces of information into an internal, mental network (Hiebert & Carpenter, 1992). Thus, the development of a conceptual understanding must have a student's current understanding as a basis (Simon & Tzur, 2004). Relationships are based on similarities and differences and, in a hierarchical way, on general and special cases, where a piece of information may include parts of another piece of information (Hiebert & Carpenter, 1992).

Tall and Vinner (1981) describe a difference between a person's concept image, and the formal concept definition. A person's concept image is the cognitive structure associated with a specific concept. It is a mental picture of properties and processes related to the concept (Tall & Vinner, 1981). The concept image develops over time, and with new experiences. The concept image, to a great deal, depends on the specific examples of the concept that a person has been presented to. Thus, a possible discrepancy between concept image and concept definition may occur with, for example, tasks

covering only a limited part of the aspects related to the concept (Niss, 2006). The part of the concept image that a student activates in a specific situation can be called the evoked concept image (Tall & Vinner, 1981). At times, a student's concept image will be challenged in some way. It may be either by meeting a situation where the mental picture is not covering enough or is not clear enough in relation to the demands of the situation. The new ideas are thus assimilated (Piaget, 1952) with what the student already knows, adding to the concept image. It may also be that the concept image is in contrast with new experiences, and requires the student to change the mental picture in some way to incorporate the new ideas. This is what Piaget (1952) describes as accommodation, which may be seen as a two-step process, where the first step is the adjustment of the existing concept image, and the second step is an assimilation of the new ideas.

For the purpose of this paper, a conceptual challenge is to make the necessary considerations of, and to properly use the (non-trivial) mathematical concepts, required in order to solve the task. For a task to include a conceptual challenge, there needs to be some kind of discrepancy between students' current (and evoked) concept image and a suitable concept image for the task.

### **Creative challenges**

Creativity is defined as “the use of the imagination or original ideas to create something” (Creativity, n.d.). In a school setting, and relating to mathematical problem solving, mathematical creativity can be defined as a process resulting in what is, to the solver, a new solution (Sriraman et al., 2013). Hence, the solver, rather than using an available template has to create her new solution method. The definition does not contradict the idea that problem solving skills can be achieved at a basic level, as well as at a more advanced level. However, as problem solving does not mean following a given algorithm, the problem solving process is hard to predict. Explorations, and hypothesizing may well be part of a problem solving process. To argue that a familiar method is reasonable to apply in a new situation may also be defined as creating a substantial part of a solution method. The characteristics of tasks are important in catering for a learning environment where problem solving is made easily available to the students (e.g. Jonsson et al., 2014; Stein & Lane, 1996).

The definition of a creative challenge used in this research, is that the challenge is involved in the creation of what is to students, a new solution method, or the selection and modification of a familiar method in a new situation where the choice of method is not obvious. This can be either the creation of an overall method, sequencing a number of well-known and/or new sub-methods. Or it can be the creation of a new sub-method, as part of an overall solution method. Thus, for it to be a creative challenge, there needs to be a discrepancy between students' prior experiences and a conceivable method.

### **Task selection and (re)design to reach learning goals**

The discrepancy between task requirements and students' concept image and previous experiences is here used as an indicator of the challenges of a task. Considering (reasonable) task challenges to be valuable to students' learning (Hiebert & Grouws, 2007; Jonsson et al., 2014), the discrepancy also refers to the opportunities to learn. Depending on the selection and the (re)design of tasks, different learning goals may be possible to obtain (Stein & Lane, 1996). Specific learning goals, and students' current state of knowledge are important factors for teachers when making informed teaching

decisions (Simon & Tzur, 2004). The decisions made in a selection and (re)design process can gain strength if informed by possible discrepancies and students' approaches to tasks.

## Purpose

The purpose of this paper is to present and discuss a structure for the selection and (re)design of tasks, to include conceptual as well as creative challenges in a task. The aim of this is to empirically study the effects of the design structure with both students and teachers. A further aim is thus that the structure will be of help to teachers, but possibly also test designers, textbook authors and others participating in the selection and (re)design of tasks used for the teaching and learning of mathematics.

## A structure for task selection and (re)design

This study, in line with the development of the framework for identifying conceptual and creative challenge, has a focus on discrepancies between students' concept image and their experiences with different methods, and what is required of them to solve a task. The discrepancy is a way to describe the opportunities to learn. By selecting and (re)designing tasks to fit a discrepancy to a specific learning goal, the opportunities to learn can be enhanced. There are assumptions about a student's knowledge, concept image, mathematical background and way of approaching a task, but may as well be assumptions of a (rather homogenous) group of students (Simon, 1995). The effects of a solution process depend on the learners' goal with the activity, possibly not tightly related to a learning goal, but for example to solve the task. Considering the importance of textbook tasks in mathematics classrooms, the structure makes use of existing tasks, gives support to an evaluation and suggests a direction for modification to these tasks.

1. The starting point of the structure is the learning goal. A well-defined learning goal is important to create a suitable task (Brousseau, 1997; Brousseau & Warfield, 2014, Simon, 1995). The learning goal is here described as aspects of a desired concept image. The description is focused on the concept(s) included in the learning goal, but also assumes that the learning goal is a clear widening of the understanding of a concept or the addition of a new concept (or property thereof).

*Example: The learning goal is to develop a concept image including that unknowns can be represented as variables, and two unknowns can be related to each other through different relations and represented algebraically. An unknown can be part of several relations. Through such a system of relations each of the unknowns can possibly be determined.*

2. The student's current state of knowledge (Simon & Tzur, 2004) is described in terms of a concept image and of experiences with solution methods linked to the mathematics in focus.

*Example: The student's concept image is assumed to include that unknowns can be determined through the use of equations, where the unknown is represented by a variable and related to constants and coefficients in an equality. Methods for solving equations algebraically are familiar, as are trial and error approaches to tasks.*

3. A candidate for a task in the area of the learning goal is found in the textbook.

*Example: A group of friends visit a coffee bar. Some order coffee at the price of 16 kr per cup and some order caffè latte at the price of 24 kr per cup. When the bill arrives the total cost is 296 kr. How many had a cup of coffee and how many had caffè latte if there were 15 friends?*

To be able to perform an evaluation of the suggested task a conceivable solution method and the possible creative and conceptual challenges related to these solutions are needed. The evaluation is based on the definitions of the challenges presented above.

4. Conceivable solution methods are proposed. Conceivable in this sense makes it necessary to also consider that the learners' goal is possibly not primarily the initially defined learning goal, but rather solving the task.

*Example: The task can be solved in several way. Here, two example are presented.*

*a) The task can be solved by setting up and solving a system of equations*

*b) The task can also be solved by a trial and error approach.*

5. Possible creative and conceptual challenges are visualized. The discrepancy between the proposed methods and students' prior experiences gives indications of creative challenges. The discrepancy between a, for each solution method suitable concept image, and an assumed concept images indicates possible conceptual challenges included in the task.

*Example, creative challenge: a) Setting up a system of equations, and solving this is not familiar to the student and will thus be a creative challenge.*

*b) The student has experience with using trial and error to find the value of an unknown. In other context she has also experienced two unknowns, such as when suggesting a format for a rectangle a specific area. This will not be a creative challenge to the student.*

*Example, conceptual challenge: a) Not included in the student's concept image is how two variables can be represented in two relations. Further, the contexts, with relations based on two different quantities (number of cups and cost) requires the student to use the concept of unknowns and their relation to each other in a more flexible way. Thus, this is a conceptual challenge*

*b) When using a trial and error approach to solve the task, the student does not have to consider the relations of the two unknowns and how to represent them algebraically to the same extent. The approach is deemed to include no (or a low) conceptual challenge.*

6. The possible challenges of the task are compared to the learning goal. The comparisons indicate in what way a task can be redesigned. If there are more than one conceivable solution method to the task, it is also important to consider all of these.

I) If the solution method avoids addressing the learning goal and the desired concept image, the task design should make the approach less favorable. Similarly, if the challenges is too small to address the learning goal, the design needs to consider this.

II) If the challenge related to the solution method is deemed to be too high, modifications to the task can be made if the learning goal can still be reached.

*Example: I) The use of the method of trial and error in this case might not contribute to a conceptual challenge in a desired way, and might be possible prevent.*

*II) It is possible that the conceptual challenge, including a flexible use of unknowns related to two different quantities is too high. It might be possible to redesign the task so that this aspect is not included, however, still including a conceptual challenge addressing the learning goal.*

7. Suggestions for adjustments of the task to meet the requests of the evaluations.

*Example: II) Change the requirements to possibly lower the conceptual challenge of setting up and solving a system of equations: “Two families visit a coffee bar. Some order coffee and some order caffè latte. The Simpsons order 3 coffee and 2 latte, and the total cost is 96 kr, while the Bundys order 1 coffee and 3 latte, and their total cost is 88 kr. How much does a cup of coffee cost, and how much does a cup of caffè latte cost?”*

*I) Change the numbers of the task (and therefor also the context) so that trial and error is made less attractive to use: “Two families are building a shed each. For the exterior they need panel boards of different dimensions. They need thin panel boards and wide panel boards. The Simpsons buy 171,5 meters of thin panel boards and 39,5 meters of wide panel boards, and the total cost is 3692 kr, while the Bundys buy 48,2 meters of thin panel boards and 149,7 meters of wide panel boards, and their total cost is 4364 kr. How much does each of the different panel boards cost per meter?”*

A redesign of the task takes into consideration all the information from the evaluation. A process of evaluating and redesigning may iterate until a desirable task where the discrepancy between the suitable concept image and the current concept image coincides with the learning goal.

## Discussion

Following this theoretical paper are empirical studies of how the proposed structure for task design works in relation to both students and teachers. The next step is to try the structure, and to redesign a number of tasks starting with a specific learning goal. Yet another aspect to examine is the way teachers make use of the structure, and the way they understand the included terminology to enhance the opportunities for learning for students through task solving. There may be aspects where the theoretical construct does not oblige to the circumstances. On the other hand, the structure may possibly serve as a foundation for task design and for further elaboration on how this can be done.

One aspect to consider is how tasks work in a social context. Solving tasks and overcoming challenges together with others implies that, along with reconfiguring ones concept image, it may prove necessary to also create meaning within the group (Hiebert & Grouws, 2007). Included in such work should be considerations regarding how homogenous the concept images of a group of students really are.

The reflexive relationship between, for example a teacher's considerations of a student's work with a task and the design of the task, is likely to continue as the task is in use. As well as redesigning the task after the lesson, a teacher may also act in the moment to answer to a new evaluation of the situation. For example, as a teacher, it may not at all times be possible to fully capture what understanding of a concept implies. It is therefore important to let the task design structure and the evaluation phase continue during and after the task is used in the classroom. As one way of looking at understanding is to consider the difficulties a student encounters, the discrepancy between the suitable and evoked concept image may be possible to reformulate as the task is used in the classroom (Sierpiska, 1994; Simon, 1995).

# The Influence of Teacher Guides on Teachers' Practice: A Longitudinal Case Study

Ljerka Jukić Matić<sup>1</sup> and Dubravka Glasnović Gracin<sup>2</sup>

<sup>1</sup>Department of Mathematics, University of Osijek, Croatia; [ljukic@mathos.hr](mailto:ljukic@mathos.hr)

<sup>2</sup>Faculty of Teacher Education, University of Zagreb, Croatia; [dubravka.glasnovic@ufzg.hr](mailto:dubravka.glasnovic@ufzg.hr)

*Keywords: Longitudinal case study, teacher guide, textbook mobilization.*

The issues concerning the use of curriculum resources such as teacher guides and textbooks are important because they can promote a teacher's pedagogical design capacity, or a teacher's ability to use personal resources to adapt the curriculum materials and to achieve productive and beneficial instructional episodes in the classroom (Davis & Krajcik, 2005).

From the idea of teaching as design, Brown (2009) built a Design Capacity for Enactment Framework (DCE) which represents the idea that the curriculum resources and a teacher's personal resources both affect the designing and enacting of classroom instruction. Viewed together, the factors of the curriculum resources and teachers' resources provide a basis for understanding teachers' use of curriculum resources in terms of offloading, adapting, and improvising. These three concepts are different types of mobilization of curriculum resources and are best understood as a spectrum of agency or responsibility for guiding instruction (Brown, 2009). The voice of the curriculum resource refers to how the authors or designers of the materials are represented and how they communicate with the teacher (Remillard, 2012). Remillard (ibid) distinguishes between talking *through* the teacher and speaking *to* the teacher. Most curriculum resources place primary emphasis on what the teacher should do and this is denoted as talking *through* teachers. When the resource communicates with teachers about central ideas in the curriculum, this denotes speaking *to* the teacher. Some authors have argued that speaking *to* teachers is one way that curriculum resources can be designed to be educative for teachers (Davis & Krajcik, 2005). In this way, a curriculum resource offers transparent and direct guidance related to the reasons and purposes underlying task selections (design rationale) or in anticipating student responses (Stein & Kim, 2009).

Previous results on the utilization of resources in mathematics instruction in Croatia (Glasnović Gracin, 2011) show that the textbook is the primary resource in teachers' lesson preparation; the next most frequently used resource is the accompanying teacher guide. In 2014, new school textbooks were approved by the Croatian Ministry of Education for the subsequent four-year school cycle. Since the planned curriculum had not been changed, the new editions of the most frequently used mathematics textbook series did not undergo significant changes. However, in line with recommendations from the Ministry of Education, the teacher guides that accompany the textbooks were revised to include, for example, opportunities for discovery learning.

This situation, whereby the teacher guides were revised in 2014, while the planned curriculum and the textbook content remained the same, prompted us to conduct an investigation into the influence of teacher guides on teachers' practice. The study encompassed the following questions: 1) What are

the differences in the structure, textbook mobilization and voice between the two editions of the teacher guide? 2) How does the teacher guide influence the use of the textbook in the observed mathematics lessons? Do the changes in the content of the new edition of the teacher guide cause a change in teacher practice?

The study was conducted in two time spots, in 2013 and 2017. It encompassed analysis of the two editions of the teacher guide for grade six (published before and after 2014), classroom observations, and interviews with two experienced mathematics teachers in Croatia. Both of the teachers chosen for this study used the same textbook series in 2017 as they did in 2013. The analysis of the transcribed interviews, observation notes and teacher guide content focused on the different mobilizations of resources (offloading, adapting, improvising). The interviews also provided an opportunity for the teachers to explain why a particular type of resource mobilization was used.

The results show the relative stability of teaching practice, but suggest, however, that the teacher guide can have an influence on the instruction. The analysis of the teacher guides showed that both editions have the same structure. The voice of the guides can be described as talking *through* the teacher, but the design of the activities in the new edition can be defined as transparent. Moreover, the new edition contains additional activities and approaches such as discovery learning. While for most lessons the old teacher guide encourages offloading, the new guide additionally suggests numerous activities that do not use the textbook as a mediator, which promotes adapting and improvising with curriculum resources. In terms of the teachers' practice, the results show that the new edition of the teacher guide inspired the participants to design their own inquiry-based learning activities and that offloading is utilized less often. This indicates that the teacher guide can have an educative impact on teachers, supporting their use of active teaching methods in the classroom.

# Community documentation targeting the integration of inquiry-based learning and workplace into mathematics teaching

Elissavet Kalogeria and Giorgos Psycharis

National and Kapodistrian University of Athens, Greece

[ekaloger@math.uoa.gr](mailto:ekaloger@math.uoa.gr), [gpsych@math.uoa.gr](mailto:gpsych@math.uoa.gr)

*In this paper we describe the process of designing and implementing inquiry-based tasks relating mathematics and workplace context, through the collaboration of four teachers from different schools. Our focus is on the factors that influence the forms of inquiry integrated in community documentation. A common open task took different forms of inquiry during the implementation depending on factors such as the students' mathematical abilities, the specificities of the different school contexts and the prerequisite mathematical knowledge. The process of teachers observing each other's classroom implementations (hetero-observation) became the incentive for subsequent transformations of the shared resources, favoring the shifts from one form of inquiry to another.*

*Keywords: Inquiry-Based Learning, Workplace context, Community documentation.*

## Introduction

The reported study took place in the context of the European-funded project Mascil ([www.mascil-project.eu](http://www.mascil-project.eu)) that targeted mathematics and science teachers' professional development (PD) through the integration of inquiry-based learning (IBL) and workplace contexts into their teaching. In this paper, we study the process of design and implementation of resources by a group of mathematics teachers from different schools who collaborated to conceive IBL tasks stemming from the 'Kite making industry' that was selected by them as the workplace context to develop their design. The importance of introducing inquiry into the teaching and learning process has been recognized by the existing research (Boaler, 1998) and constitutes a main aim of many mathematics curricula and teacher education programmes. Also, there is a growing interest concerning the nature of resources and contexts facilitating the integration of inquiry into classroom teaching (Doorman, 2011). This integration increases the complexity of teaching as it brings to the fore issues such as the nature of the designed tasks, the teaching management and the students' learning (Artigue & Blomjoi, 2013), thus teachers are reluctant to use IBL in their everyday practices (Bruder & Prescott, 2013). At the same time, it has been indicated that workplace contexts may offer rich opportunities for teachers to introduce authentic situations into their teaching (Wake, 2014) through open problems. The design and implementation of resources for mathematics linking IBL and workplace contexts constitutes an innovation since existing curricula rarely include this type of materials, so teachers' collaboration in this direction is crucial. Existing literature indicates the facilitative role of teachers' participation in communities in their professional development and more specifically when introducing educational innovations (Lerman & Zehetmeier, 2008) such as the one targeted by Mascil. However, how teachers collaborate to design and implement innovative tasks linking IBL and workplace is an area that requires further study. Under this perspective, in this paper, we explore the factors that influence the design/implementation of IBL tasks relating mathematics and workplace contexts during collaboration among teachers from different schools.

## Theoretical framework

The integration of IBL into the mathematics classrooms presupposes the transformation of the traditional teaching practices. Doorman (2011) indicates the shift in the teachers' roles from telling to supporting, scaffolding and fostering students' reasoning, while students pose questions, inquire, explain, extend, evaluate and collaborate. He highlights the need for new classroom norms and learning environments incorporating open problems with multiple solutions through the use of tools and resources. Artigue and Blomjoi (2013) also indicate the 'authenticity' of questions and students' activity that requires connection with real life and out-of-school questions fostering the experimental dimension of mathematics. Inquiry can take three forms (ibid): (a) Structured: The teacher provides the students with the appropriate method/materials to solve the given problem. (b) Guided: The teacher provides the students with the necessary materials and the students have to find the appropriate strategies for solving the given problem. (c) Open: The students have to find problems or questions they would like to solve and chose the methods/materials for solving them.

The crucial role of resources has been discussed in terms of the documentational approach of didactics (DAD, Gueudet & Trouche, 2009) focusing on teachers' interactions with resources as a way to capture teachers' professional development. The term *resource* describes a variety of artifacts such as a textbook, a piece of software, discussions with colleagues etc. An integral part of teachers' professional activity is the search, selection and modification of resources as well as their implementation in class working individually or collectively with colleagues. This process – called documentational genesis - results to a document after classroom implementations. Through a class of professional situations and teachers' experience, the existing resources are modified as documents that can be further transformed to new documents over time. The process of gathering, creating and sharing resources to achieve the teaching goals in the context of a community is called *community documentational genesis* resulting in the *community documentation* composed of “the shared repertoire of resources and shared associated knowledge (what teachers learn from conceiving, implementing, discussing resources)” (Gueudet & Trouche, 2012, p. 309). In this study, the group of participating teachers is considered as a community of practice (Wenger, 1998) characterized by mutual engagement (collaborative norms and relationships), joint enterprise (common goals) and shared repertoire (collaborative production of resources). IBL has been studied in relation to different theoretical frameworks (Artigue & Blomjoi, 2013) but not in relation to DAD and community documentation. Linking IBL and workplace contexts is a challenging research area (Triantafillou et al., 2016) in terms of the factors that influence teachers' collaborative work. In this paper, we explore the community documentation aiming to link IBL and workplace contexts by the following research question: Which factors influence the forms of inquiry integrated in community documentation of IBL tasks relating mathematics and workplace contexts?

## Methodology

### Context and participants

The implementation of Mascil in Greece included thirteen groups of 8-12 practicing teachers from mathematics, science and technology. In each group, the teachers collaborated in two cycles of design→implementation→hetero-observation→redesign with reflection as a core element, for a

school year with the support of a teacher educator. PD meetings took place before and after each implementation. In the first two PD meetings, teachers were introduced to the project rationale as well as to the main principles of IBL and workplace mathematics. In the next meetings, teachers collaborated in subgroups to transform existing Mascil tasks or design new ones in the same spirit and reflect on their experiences from the implementations. In the end of the project, the participating teachers were interviewed so as to address the impact of the PD program on their professional development. In this paper, we focus on a subgroup of four qualified mathematics teachers: tA (PhD), tB (Master degree, teacher educator), tC (Master degree) and tD (teacher educator). They collaborated in the design and implementation of two tasks (*Stairs* and *Kites*). Here we study the case of *Kites*. Implementation took place in different grades (Figure 1) in four public secondary schools of Athens. tB's school is experimental, i.e. it is connected to the university, it supports experimental teaching methods and students are selected after examination. Hetero-

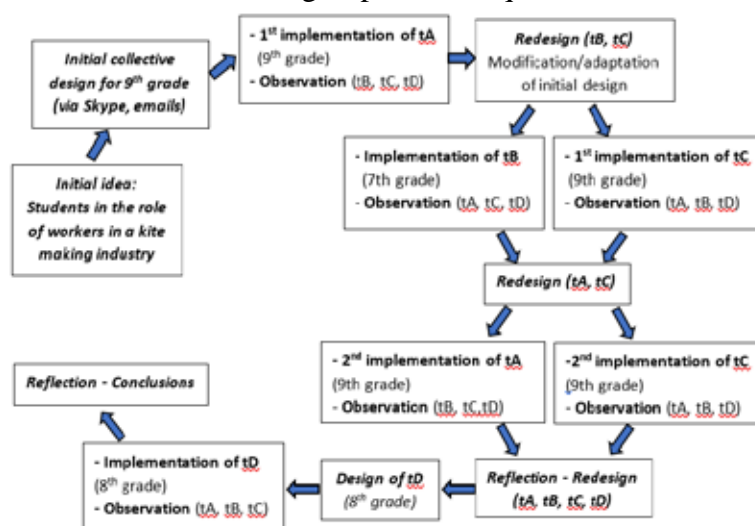

Figure 1: The process of implementation

observation informed the subsequent transformations of the initially shared resources.

### The task

The task was formulated gradually through discussions among the four teachers having as a starting point the idea of kite making. Factors that influenced the task design were the multiplicity of issues inherent in the construction of kites, the targeted mathematical content and its connection to the curriculum as well as the need to leave space for the students to become partners in the formulation of the problem. The initial common assumptions were: (i) *The initial idea*: Students' adopt the role of employees in a small kite making industry aiming to optimize the amount of paper used. (ii) *Preparing the implementation*: Students work in groups, search for the following information in real-life sources and upload it in an e-class folder: (a) the kind of paper used for kites (dimensions, package, cost); (b) shapes/dimensions of kites with a focus on: regular hexagon of diameters 80cm, 100cm and 120cm respectively that can be consisted of 6 equilateral triangles, or 2 isosceles trapezoids, or 4 right trapezoids with different colors; regular octagon of diameters 80cm, 100cm and 120cm respectively consisted of 8 isosceles triangles; and rhomboid. (iii) *Integrating IBL*: Based on the students' collected information, the regular octagon and the rhomboid were excluded.

### Data collection and analysis

The collected data consisted of: (1) teachers' e-mail messages; (2) transcripts of PD meetings; (3) teachers' resources (lesson plans, worksheets, ppts, digital files); (4) teachers' notes from hetero-observation; (5) teachers' activity reports; (6) teachers' interviews; (7) videos from classroom

implementations. Following DAD methodology (Gueudet & Trouche, 2012): (a) we analyze teachers' work in time periods in and out-of-class (reflexive investigation principle); (b) we address their decisions taken in order to formulate their design through its use (design-in-use principle); and (c) we consider their work embedded in and influenced by different collectives such as the PD meetings (collective principle). We used data from different time periods: excerpts from their hetero-observation notes that took place before and after their own implementation, the developed materials and their transformations over time including the arguments with which they documented their options and presented in the PD meetings and in their activity reports.

## Results

### Preparation and initial designs

In this phase, the teachers worked on the initial idea aiming to formulate and orient the problem. Their documents included preparatory activities for hexagonal kites of 80cm diameter (since they were the most common type) aiming to help students understand that: (1) this kind of kite cannot be constructed by a single rectangular sheet of paper, thus the hexagon has to be divided in smaller different geometrical shapes; (2) hemming is necessary (i.e. each sheet edge is creased and rolled over onto itself) in order to make the kite robust; (3) companies save paper by using the remnants for the tail; (4) paper cost depends on the type of package and paper size. The initial document of tA for the 9<sup>th</sup> grade included an open task and it was further refined collectively by the group of teachers as follows: *"We are workers in a kite making company. Our director suggests reducing the waste of paper. So today we will work in groups focusing on the case of regular hexagon kites of 80cm diameter to explore the ways by which a hexagonal kite can be composed by different geometrical figures and the amount of paper needed. The dimensions of the paper we use are 70×100, the package includes 46 pieces and costs 23€. In order to reduce the paper, our company decided to construct the kite tail with newspapers instead of the remnants (as we used to do). Thus, our aim is to minimize the remnants of the paper by exploring how to combine different geometrical figures. These figures can be: (a) 2 isosceles trapeziums; (b) 4 rectangular trapeziums; (c) 3 rhombs; (d) 2 rectangles and 2 isosceles triangles; (e) 6 equilateral triangles. For gluing the internal figures, we use adhesive tape while for the external segments comprising the perimeter of the hexagon we use hemming. The hem is an isosceles trapezium of 4cm height".*

Students work in groups and study one of the above five cases. Below, we provide a brief description of the corresponding activities: (1) Students are given an 8×3 table (Figure 2). The first row includes two rectangles representing respectively a real sheet of paper (with known dimensions) and a 1:4 scale one. The students have to compute the dimensions of the 1:4 scale rectangle. The next six rows correspond to the above mentioned five combinations by which hexagonal kites can be constructed. In the second and the third column, regular hexagons are given representing respectively a real kite and a 1:4 scale one. For each combination of shapes the

**Figure 2: A completed worksheet of activity 1**

students have to divide the given regular hexagon in corresponding parts and compute both the dimensions of the real kite and the ones of the 1:4 scale. In the last row, the students are asked to compute the dimensions of two given isosceles trapezoids representing the hems of the real kite and of the 1:4 scale respectively. (2) Each group announces the results to the whole class. (3) In a millimeter paper and in a 1:4 scale each group represents the real rectangular sheet and explores if a regular hexagon with peripheral hems fits within it. Then, they confirm that this construction is not possible through the use of a given Geogebra file. (4) The students cut with scissors the geometrical figures they worked on in the first activity (including their peripheral hems), put them down on millimeter papers (1:4 scale of the real paper) and glue them when achieving the best coverage (minimizing gaps). In this activity, students experiment to achieve the best coverage by combining their own geometrical figures with other groups' figures. They confirm their findings through the Geogebra file. (5) The groups exchange their cut geometrical figures to optimize their coverage.

The computations mentioned above, required the knowledge of properties of regular polygons, Pythagorean Theorem and trigonometry taught in 8<sup>th</sup> grade. The four teachers planned to implement the task as follows: tA and tC in 9<sup>th</sup> grade, tB in a 7<sup>th</sup> grade and tD in 8<sup>th</sup> grade. So, they adapted the initial design taking into account the respective curriculum and their different contexts. tC, for instance, whose class included many low achievers, expressed her concerns about her students' required knowledge. Thus, she designed a preparatory lesson aiming to remind the properties of the basic geometrical figures embedded in the kite construction as well as the steps for constructing a regular hexagon with ruler/compass. Then, the students were

**Figure 3: Dividing a regular hexagon**

asked to divide given regular hexagons in corresponding parts (see a filled worksheet in Figure 3). At the same time, tB excluded the computations of the given figures' dimensions, since the 7<sup>th</sup> grade students do not have the required knowledge. His emphasis was on the concepts of scale and symmetry. In his design the regular hexagons and their geometrical components (both with peripheral hems) were given (Figure 4) and the students were asked to reproduce them in a sheet of paper (1:4 scale) and cut their components with scissors. He targeted the exchange of geometrical figures among the groups and the exploration of the best coverage with different combinations by using more than one sheets of papers. Finally, tD exploited the initial collective design for teaching the properties of regular hexagons in the 8<sup>th</sup> grade. Summarizing, community documentation in this phase revolved around a common body of activities of the initial design. Besides, they concentrate mainly on adaptations related to the curriculum and to their students' mathematical abilities/weaknesses.

	The kite	...and its components
2 isosceles trapeziums		
4 right trapeziums		
3 rhombs		
2 isosceles triangles & 2 rectangles		
2 isosceles triangles & one rectangle		
6 equilateral triangles		

**Figure 4: Hems and geometrical components**

### Implementations and redesigns

The first implementation took place in a 9<sup>th</sup> grade classroom of tA. Despite the fact that the whole process fascinated the students, but it was time consuming since: (1) Mistakes in the calculations

and wrong application of geometric properties were noticed. (2) Each group undertook the calculations of a specific combination of geometrical components and communicated the results to the others. This process has been time consuming and students of one group may did not understand the calculations of the other groups. (3) The construction of the 1:4 scale hexagon on a millimeter paper and the cutting of its components based on the previous calculations were also time consuming. These difficulties resulted in the limitation of students' exploratory activity (e.g., there was no time left for exchanging the cut geometrical figures across the groups) and the failure to complete the lesson in the foreseen two hours.

The process of hetero-observation allowed the rest of the teachers to modify their initial designs by giving students ready-made materials (i.e. rectangles  $17.5 \times 25$  cm representing the real sheet for kites and regular hexagons of diameter 20 cm with hems representing a real kite, all in a 1:4 scale) so as to have more time for exploration. The lesson of tB in a 7<sup>th</sup> grade classroom of his experimental school (where exploration and group work constitute common practices) embodied elements of both guided and open inquiry. He prioritized the use of manipulatives and digital representations (Geogebra) as a main element of IBL. After experimentation with different combinations for covering the  $17.5 \times 25$  sheet, two groups of students decided that the optimal coverage of a sheet was achieved by the use of 2 rhombs and 2 equilateral triangles (Figure 5). Thus, 3 sheets include 6 rhombs and 6 equilateral triangles and allow the construction of 3 kites (2 kites with rhombs, 1 kite with equilateral triangles). This way the numbers of equilateral triangles and rhombs needed should be multiples of 6 and 3 respectively. Since each package includes 46 pieces, the students reached the notion of Least Common Multiple (LCM) as appropriate for finding the best solution (we note that LCM was not explicitly part of the teachers' design). Therefore, with three packages ( $138 \text{ sheets} = \text{LCM}(3, 6, 46)$ ) they could construct 138 kites (46 with equilateral triangles and 92 with rhombs). This finding provided an incentive for other groups to optimize the final solution. The lesson closed with a whole class discussion where the best solution was chosen and the connections to the realistic context (kite making industry) became explicit.

**Figure 5: the combination of two groups**

The emergence of the notion of LCM was not taken into account in the initial design and challenged further the teachers' reflection. Thus, the second implementations of tA and tC were characterized by a more conscious attempt of the two teachers to bring to the fore the notion of LCM. However, while tA's students' exploration resulted in better solutions in terms of paper save and diversity of combinations, tC's students faced a lot of difficulties. For instance, one group of tA used 4 sheets to construct 4 kites with three different combinations (i.e. 2 kites with trapeziums, 1 with equilateral triangles, and 1 with 2 isosceles triangles and 2 rectangles). Through the use of LCM, these students concluded that with the use of 92 sheets they can construct 92 kites of the above three different combinations. During her implementation (9<sup>th</sup> grade), tC faced the difficulties of tA's first lesson and also many students did not understand the role of hemming. As a result, the notion of LCM was not exploited to offer multiple solutions. tC in her activity report mentioned "I should have engaged them in the construction of a real kite with the use of paper and wooden straws". A comparison of the two implementations shows that tA followed an open form of inquiry taking more time than

expected (3 teaching hours instead of 2), while tC - due to her students' low mathematical abilities - followed a structured form of inquiry downgrading the demands of the task.

The last implementation was carried out by tD in a 7<sup>th</sup> grade classroom. By observing the other teachers' teaching, she realized that many problems stemmed not only from the calculations but mainly by obstacles in the process of groups' exchange of geometrical components. Thus, she decided to support the communication among the groups by taking the role of 'crier', 'circulating' around and showing different geometrical figures so as to facilitate the choice of other groups' figures that minimize the free space in their sheets (i.e. she showed specific groups' solutions to the other groups highlighting the free parts of the sheet and motivating them to conceive its best coverage or its reconstruction by using some of their own geometrical figures). Besides, this choice was also related to the fact that the students' initial attempts left uncovered big parts of the sheet. In her activity report, tD considers that "A real kite construction in the classroom would have revealed to the students that a large amount of paper is lost". Her implementation embodied both guided and open inquiry: the first part of the worksheet offered guidance to the students in the introduction of the corresponding notions in the realistic context while in the second part of the lesson tD emphasized the importance of communication among the groups keeping a mediating role for her.

## **Discussion and concluding remarks**

In the preparation and initial design phase, the main issue was the orientation of the task consisted of: (i) the openness of the task; (ii) the embodied mathematical concepts; (iii) the specificities of constructing a real kite (kinds, dimensions, hemming, paper packages, costs); (iv) the complexity of mathematical exploration (geometrical figures and their properties, multiplicity of solutions); (v) the connection to the workplace context (cost, constraints in the use of paper) and the need of students' engagement in collecting relevant information; (vi) the roles of teachers and students; and (vii) the teaching management. The data collected by the students revealed the specificities of kite construction and the teachers' documents were adapted to their different school grades/contexts.

In the implementation phase, the initial open task took different forms of inquiry. The initial open approach of tA, brought to the fore issues that took time from inquiry. The open inquiry increased the level of uncertainty and resulted in not having a solution by the end of the first lesson. The process of hetero-observation was critical since: (1) tB adopted guided and open inquiry bypassing the time-consuming elements of tA's teaching and including ready-made materials to ensure more time for inquiry. This choice facilitated the emergence of concepts not initially anticipated by the teachers (i.e. LCM) and left space for unexpected solutions to emerge. (2) tA (in her second lesson) and tD followed guided inquiry aiming to facilitate students to approach gradually the notion of LCM and help them to find as many solutions as possible. They used ready-made manipulatives and their teaching management was aligned to support IBL and communication between the groups (i.e. tD acting as crier) targeting intentionally the emergence of different solutions through the notion of LCM. This kind of activity strengthened the connections to the workplace context and led to the extension of the mathematical inquiry (i.e. multiple solutions from tA's students). Finally, the tC's belief concerning her students' low mathematical abilities resulted in a structured form of inquiry. She tended to decrease the level of uncertainty by providing resources aiming to remind

students the properties of the basic geometrical figures embedded in the kite construction. However, the low mathematical abilities of tC's and tD's students were again a factor that limited the emergence of multiple solutions. Another factor was students' difficulties in understanding the role of specific parts of kite construction (e.g. hemming). This was indicated in tC's and tD's reflections where they stressed the importance of engaging students in the construction of a real kite.

Summarizing, the factors that influenced the adopted forms of inquiry were: teachers' conceptions of their students' mathematical knowledge; the different school contexts (e.g., differences in students' prior mathematical experience, classroom norms, familiarization with IBL approaches); and the range of the prerequisite knowledge. The connection to the workplace context favored the emergence of mathematical concepts but the limited available time led teachers to structured or guided forms of inquiry. Hetero-observation facilitated the sharing of teachers' associated knowledge by promoting awareness of the above factors and became the incentive for subsequent modifications of the shared repertoire of resources, favoring shifts from one form of inquiry to another. In conclusion, these factors influenced the community documentation indicating hetero-observation as a catalyst mediating in a dynamic way the evolution of design and implementation.

# The use of variation theory in a problem-based task design study

Berie Getie Kassa<sup>1</sup> and Liping Ding<sup>2</sup>

<sup>1</sup>Bahir Dar University, Ethiopia & NTNU, Norway; [beriekassa@gmail.com](mailto:beriekassa@gmail.com)

<sup>2</sup>NTNU, Norway; [liping.ding@ntnu.no](mailto:liping.ding@ntnu.no)

*The aim of this pilot study is to test the usefulness of variation theory as a theoretical framework in guiding the researcher to design the main study of developing students' deep learning in mathematics. Both Marton's variation theory of learning and Gu's theory of teaching with variation were used in the design-based pilot study. Two teachers and 106 Grade four students from an elementary school in a large north-west city in Ethiopia participated in the pilot study. The pilot study data included transcripts of audio-recording of preparatory meetings (the first author with the two teachers) and students' interview, video-recording of lesson observation, and pre and post-tests. The pilot study topic was of learning concepts of area and perimeter of rectangles. We find that the theoretical framework of variation helped us to address the systematic use of patterns of variation and invariance in the problem-based task design and to analyze the three patterns of variation in the problem-based tasks implementation in the classroom learning.*

*Keywords: Variation theory, patterns of variation and invariance, problem-based task design.*

## Introduction

School mathematics curriculum has been significantly reformed from kindergarten to upper secondary school in Ethiopia. Consequently, school mathematics is now viewed from a dynamic and experimental perspective rather than only as a body of strict and logical knowledge already in existence (MOE, 2013). However, the national learning assessments have constantly shown that students have achieved poor results in all areas, and their achievement in mathematics is the least (MOE, 2013). For example, the fourth national learning assessment (FNLA) result has shown that the overall test performance of grade 8 students in 2013 was far below the national minimum achievement standard of 50%, and their achievement in mathematics is the lowest (the composite average became 25.65%), where 50% of the students scored at or below a score of 22.5% similar in both sampled grades 4 and 8 (MOE, 2013). According to the FNLA reports in 2013, the education of mathematics should receive special emphasis in all deliberations, for example, the use of teaching and learning resources, and professional development of teachers about innovative pedagogies.

The overall objective of this study is therefore to make a contribution to developing the quality of mathematics teaching and learning in Ethiopia. This pilot study is to test the usefulness of the variation theory as a theoretical framework in guiding the researcher to design and implement problem-based tasks to improve students learning in mathematics. In this paper, we mainly focus on the following two research questions: (1) *to what extent does the theoretical framework help to design the instruction of problem-based tasks?* (2) *to what extent does the theoretical framework help to analyze the implementation of such design in the classroom?*

## Literature Review and Theoretical Framework

### Marton's Variation Theory of Learning (VToL)

Ference Marton and his colleagues in Sweden and Hong Kong have developed Variation Theory of Learning (VToL) to describe how a learner might come to see, understand, or experience a given phenomenon in a certain way (Marton, 2015; Marton & Booth, 1997; Marton & Pang, 2006; Marton & Tsui, 2004). For instance, Marton and Booth (1997) emphasized that one cannot become aware of new aspects without becoming aware of differences. If certain aspects of a phenomenon are varied while its other aspects are kept constant, then those that vary will be noticed. Every concept, situation or phenomenon has particular or critical aspects, and it is important to identify the critical aspects and the focus of students' attention should always be directed to the critical aspects (Lo, 2012). In order for students to discern the critical aspects of a concept(s), they need to experience different forms of variation in which the critical aspects of the concept(s) will be varied and not varied. Moreover, VToL addresses that for learning to occur, some critical aspects of the object of learning must vary while other aspects remain constant. According to VToL, the specific knowledge/content or capability to be gained through learning is called the object of learning (Lo, 2012; Marton & Pang, 2006; Marton & Tsui, 2004). VToL takes the object of learning as the point of departure and claims that what is being learned is highly influenced by what actually comes to the forefront of students' attention. Kullberg, Runesson and Marton (2017, p. 561) explained that "when analyzing how the object of learning is handled during teaching, the 'intended', the 'enacted', and the 'lived' objects of learning are used to differentiate between the teacher's particular goal regarding what the students should learn, what is made possible to learn in the lesson, and what the learners actually learn". The theory further suggests that how students perceive a specific object of learning depends on what pattern of variation and invariance is provided by the teacher. Four patterns of variation and invariance are identified: contrast (i.e., recognizing differences between two values of an aspect), generalization (i.e., keeping the focused feature invariant and varying other out of focus aspects), separation (i.e., separating aspects with varying values from invariant aspects), and fusion (i.e., experiencing several critical aspects simultaneously) (Leung, 2012; Lo, 2012; Marton & Tsui, 2004). Marton (2015) further proposed a new pattern of variation in which only three of the four patterns, i.e., contrast, generalization, and fusion exist as the basic ones, which are observed by learners.

### Gu's Teaching with Variation (TwV)

In parallel with Marton's theory of variation, a theory of mathematics teaching and learning, called Teaching with Variation (TwV) (*bianshi jiaoxue* in Chinese), has been developed by Gu Ling-yuan and his colleagues through a series of longitudinal mathematics teaching experiments in China (Gu, 1994). According to Gu's theory, which was highly inspired by the theory of cognitive constructivism, meaningful learning empowers learners to establish a significant and non-arbitrary connection between their new knowledge and their previous knowledge (Gu, Huang, & Marton, 2004). Classroom activities can be designed to help students to create this kind of connection by experiencing certain dimensions of variation. Gu's theory of TwV suggests that two types of variation are helpful for meaningful learning. One is called "conceptual variation", and the other is "procedural variation" (Gu et al., 2004). Conceptual variation refers to understanding concepts from multiple

perspectives. Procedural variation is progressively unfolding mathematics activities. That is, teaching process-oriented knowledge by enhancing the formation of concepts step-by-step, and experiencing problem-solving from simple problems to complicated problems (Gu et al., 2004).

Based on the above literature, we formed an initial analytical framework (see Table 1) to guide us in designing an instruction and implementing such design in the pilot study.

## Methodology

### Research Design

This study was based on the principles of design research (Cobb, Jackson, & Dunlap, 2016). According to Cobb et al. (2016), design research is a research approach that has been increasingly appreciated in mathematics education research. It can help to construct the instructional ways of promoting learning of a particular concept, while regularly studying the development of that learning, considering all components of the instructional ways, including the context in which it is carried on. According to Cobb et al. (2016), some of the main characteristics of design research approach is its highly interventionist nature, iterative design and cyclic nature. Each cycle progresses in three phases: (i) preparation and design of teaching experiments; (ii) implementation of teaching experiments; and (iii) retrospective analysis that can lead to revisions and a new cycle (Cobb et al., 2016). In this pilot study, two teaching experiments, in two fourth grade classes of 106 students, were conducted in their regular classes, during a 45 minutes period for each class. The two classes were taught by the same teachers and the study design is illustrated in Figure 1.

**Figure 1: The research process in the pilot study**

## Data Collection

106 fourth-grade students from a governmental elementary school in a city in the north-west of Ethiopia participated in this pilot study. There are four mathematics teachers teaching in Grades 1- 4 (1 male, 3 females) in the school. The researcher (first author), together with one experienced teacher and one beginner teacher, formed the pilot study group. In this study, the study group collected data through preparatory meetings, pre-tests and post-tests, lesson observations and video-recordings of lessons, students' worksheets and students' interview (See Figure 1).

## Data Analysis Procedure

We followed the three phases of each cycle progresses (Cobb et al., 2016) in our data analysis. The data analysis mainly focused on how the object of learning was designed and implemented in terms of patterns of variation and invariance of critical aspects of the object of learning within and between units of teaching, such as the problem-based tasks (for details see the analytical framework in Table

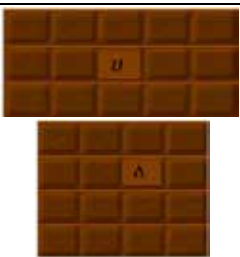

1). The analyses were made by watching the video recorded lessons and meetings, repeatedly focusing on what was planned (the *intended*), what was possible for students to discern (the *enacted*) and what the students actually learned (the *lived* object of learning). In addition, pre and posttests, students' worksheets and students' interview were also analyzed to find out students' discernment of the object of learning. The analysis of the first class (see the intervention cycle 1 in Figure 1) is based on the data of the study group's initial lesson plan, namely the problem-based task design and implementation in the class. The analysis of the second class (see the intervention cycle 2 in Figure 1) concerns more on the usefulness of the redesign of tasks, the effective design and use of tools, and the impact on students learning. Given the space of this paper, we will chiefly focus on our research questions in the analysis of the first class.

## Findings

Finding one and two below focus on reporting our retrospective analysis of the problem-based task design (namely the stage of the preparation and design of teaching experiments of the first lesson); and classroom implementation of such design in the first lesson.

### *Finding one: The usefulness of the variation theory in designing the problem-based tasks*

In this pilot study, we focused on designing problem-based tasks for improving students' mathematical understanding of the concept of area and perimeter of rectangles. The problem-based tasks were designed by referring to both Gu's terms of conceptual and procedural variations and Marton's terms of variation/invariance (see Table 1). The sequence of tasks used in the classroom instruction were designed with reference to the two problems and critical aspects shown in Table 2.

Object of learning	Critical aspects	Problems used to design sequences of tasks in the lesson
The relationship between area and perimeter of rectangles	(1) If the perimeter of rectangles is the same, then the area does not have to be the same.	(1) The figures below are two bars of biscuits. If the price of these biscuit bars is the same, which biscuit do you want to buy? Why do you choose that biscuit? What is your strategy for choosing the biscuit you want to buy? Explain your answer. Use the given grid paper to help you compare the shapes. 
	(2) A rectangle with dimensions closest together or the same (square) is the largest.	(2) A farmer has a 16 meters long fence and he plans to enclose a rectangular grazing field with it. Can you help the farmer to think of a way to enclose the largest grazing field? At what condition is the field smallest?

**Table 2: The link between the problems and critical aspects of the object of learning**

Conceptual variation was carried out to firstly emphasize certain concepts of rectangle such as its area and perimeter and hence the concepts could be more readily picked up for use in finding the relationship between area and perimeter of rectangles. In terms of procedural variation, the problems were transformed into simpler problems, so that students could solve them step by step in a progressive way, using different methods and that helped them to answer the original problem. In

addition, the second more advanced problem was designed to scale up the methods/solution techniques used by students in the first problem (connecting new and prior knowledge). Students were also used their prior measurement techniques as a procedure to find area and perimeter of rectangles. Both procedural and conceptual variation was also carried out in connecting the abstract concept, for example, mathematical formula of area ( $A = \text{length} \times \text{width}$ ), directly to its concrete correspondence (counting unit squares).

Marton's theoretical notion 'the object of learning' (Marton et al., 2004) was also used in the pilot study in that the study group aimed to develop students' learning of the relationship between the concepts of area and perimeter of rectangles. Moreover, the study group also applied the critical aspects of the object of learning to further understand students' learning (see Table 2). The two problems shown in Table 2 were designed to bring the two critical aspects into the focal awareness of learners so that they could discern them step by step. The two problems were also used to guide the design of the sequence of tasks in the classroom instruction.

*Finding two: The usefulness of the theories of variation in analyzing the implementation of the designed tasks.*

The implementation of the designed instruction was guided by both Marton's VTOL and Gu's TwV. For example, the teacher used procedurally varied approaches in implementing each of the designed tasks, in a systematic and progressive way. At the beginning of each task, the teacher asked students to conjecture the answers to each problem individually and then to compare it with their colleague's work. The teacher then conducted a discussion with students on their answers without giving any hint on the correctness of students' suggestions and did not give them the correct answers. The teacher then asked students to start a group investigation of the posed problems in a small group. Students were also encouraged to use the different tailor-made resources made available by the teacher to discover patterns in their answering. Each task was finally concluded by a whole class discussion followed by summary given by the teacher.

Marton's (2015) term of 'contrast' (i.e., recognizing differences between two values of an aspect) was used to guide the task implementation. For example, students were asked to draw rectangles by fixing one dimension of the rectangle (say, length) and varying the other (width) and vice versa to find the area and perimeter of each using resources such as strings and unit square tiles. At this stage the concepts of perimeter and area of rectangles were discerned as area is the amount of surface of a region, and perimeter is the distance around the region. In addition, students were able to realize the change in area/perimeter due to the change in length/width of rectangles.

Secondly, Marton's (2015) term of 'generalization' (i.e., keeping the focused *aspects* invariant and varying other out of focus aspects) was focused in the classroom. The analysis of students recording sheet showed that most students discovered the formula for finding the area and perimeter of rectangles easily, and they were also able to understand how area formula is related to counting unit squares covering the rectangular region. Some of students' correct findings and generalizations presented in class and written in the record sheet were: the perimeter of a rectangle equals the sum of all of its sides and this can be calculated as:  $\text{perimeter of a rectangle} = (2 \times \text{length} + 2 \times \text{width})$ ; the area of a rectangle is the total number of unit grid-squares inside the rectangles and this can be

calculated as: area of a rectangle = length  $\times$  width. Students were also able to compare rectangular shapes with fixed perimeter. At this stage students discerned the first critical aspect, that is, if the perimeter of rectangles is the same, then the area does not have to be the same. Most students were able to change their conjecture for problem one that the biscuit with largest side (the first one) was chosen to buy. In the recording sheet, most students wrote a generalization that rectangles with the same perimeter can have different area and vice versa.

Finally, Marton's (2015) term of 'fusion' (i.e., experiencing several critical aspects simultaneously) was highlighted. For instance, the relationship between the two concepts was shown by varying certain aspects (length and width) while keeping an aspect fixed (perimeter of rectangles). At this stage students were able to identify the largest/smallest rectangle among all rectangles with the given fixed perimeter. Most students were also changed their conjecture on identifying the largest grazing field with the given fixed length fencing material in problem two. In the recording sheet, most students wrote a generalization that a rectangle with a fixed perimeter would have the largest area when its length and width are equal (a square).

## Discussions and Conclusions

In this paper, we reported our retrospective analysis (Cobb et al., 2016) of using the theory of variation in both the designed instruction and the implementation of such design in the pilot study (see Table 1 & Figure 1). Our data analysis shows that the joint consideration of the two different but compatible frameworks of variation (see Table 1) helped the study group to focus on the systematic use of patterns of variation and invariance in the design and analysis of the implementation of the problem-based tasks in the classroom learning. In particular, it enables the researcher to analyze the implementation of such design to see how the students may experience and discern the critical aspects of the object of learning and to improve their learning in mathematics. The retrospective analysis of the pilot study would lead the researcher to revisions and new cycles for the main study. In particular, we aim to develop a more sufficient understanding of interrelationship of Marton's terms of 'the critical aspects of the object of learning', and the patterns of variation and invariance (Marton, 2015) and Gu's terms of conceptual and procedural variation (Gu et al., 2004) with the design-based approach (Cobb et al., 2016), to enable us to design and implement the problem-based tasks in the main study for engaging students in mathematical learning in a systematic process and at the same time to develop their own learning in mathematics.

The analysis of the pilot study also showed that the implementation of problem-based tasks with patterns of variation and invariance helped students to improve their understanding of the critical aspects of the object of learning (the relationships between area and perimeter of rectangles) significantly. After the implementation of the first lesson, as can be evident from the researcher's observation and video recording of lessons, most students were actively engaged in individual and group discussions and some students were able to grasp the concept quickly and began to make interesting conjectures from experiencing variations in the tasks. For example, most students showed progress in answering each question of the post-test with correct explanations. It was found that there were percentage increases of students understanding in discerning all the critical aspects (49% and 26.4% of students provided correct explanations, 47.2% and 56.6% of students provided partially

correct answers, in posttest questions related to the first and second critical aspects respectively), and paired-samples *t*-test result informed that it was statistically significant (with the sig. level, 0.01) when it is compared with their pre-test results. In addition to their significant progress in the post-test, during the post-lesson interview students said that they had achieved a better understanding of area and perimeter of rectangles by actively involving in the tasks. However, there are also few students who do not discern the critical aspects (3.8% and 17% of students were not able to answer the first and second questions of the posttest respectively). This is supported by the researcher's qualitative analysis result that the intended, enacted and lived object of learning sometimes did not coincide. According to Kullberg et al. (2017), well-designed tasks and examples, and patterns of variation (differences) and invariance(sameness) in teaching, however, are insufficient and does not guarantee learning, it can, at best, make it possible for learning to happen. From our analysis, the two theories can, however, offered tools that the study group can use to focus on the mathematical content taught, students' understanding of it and how to enable possibilities for learning.

## Web of problem threads (WPT) – a theoretical frame and task design tool for inquiry-based learning mathematics

Dániel Katona

Hungarian Academy of Sciences, Alfréd Rényi Institute of Mathematics, Budapest, Hungary; & ELTE Eötvös Loránd University, Budapest, Hungary; [danikatona@gmail.com](mailto:danikatona@gmail.com)

*Keywords: web of problem threads, connected task-design, anthropological theory of the didactic, reverse didactic engineering*

### Goal, Context and Methodology

The poster presented the basic concepts and a sample of the *web of problem threads* (WPT), the core element of a theoretical framework under development, and a tool for task-design in mathematics education, based on the qualitative analysis of the Pósa-method for inquiry-based learning mathematics. The WPT is the result of the research aiming at, on the one hand, theorizing the ‘intuitively’ developed Pósa method, a ‘good practice’ as it is widely used in Hungarian talent care education, and on the other hand, providing theoretical background for the development and reconstruction of the method to be applied in public education.

The term *Pósa method* refers to the nationally well-reputed three-decade-long teaching practice of Lajos Pósa, in Hungarian out-of-school weekend mathematics camps for highly talented 12-18 years old students, who form a study group for 6 years. They solve connected mathematical problems (tasks) of various kinds (regarding content area), but the focus is on discovering and discussing the mathematical ideas connecting the problems and the corresponding ‘ways of thinking’, or kernels, according to our WPT framework. The Pósa-method was developed “based in teaching as craft knowledge” (Watson & Ohtani, 2015, p. 5), lacking the construction of, or building on any theoretical framework. There is also a demand (by the Hungarian Academy of Sciences) for the re-design of the method to be applied in public education, based on a theoretical background to be built. The main goal of the research is to subsequently (re)construct the theoretical frame and the tools of the task-design of the Pósa method. The term ‘*reverse didactic engineering*’ is suggested for this research methodology (also based on the discussion in TWG 17 of CERME11).

### Theoretical Background, Steps of Theorizing and some Results

Based on mathematical content analysis, the web of problem threads has been theorized as the first step of theorizing, focusing on specific kinds of connections, common features (called the *kernels*) between the mathematical tasks (problems). According to this theorization, a set of connected tasks, in a partially fixed order, creates a *thread* of the problems. Kernel is the manifestation of a kind of connection (common feature) that creates the thread (that can actually have multiple kernels). As some problems belong to several threads, threads cross each other, forming a web, the *WPT*. The problems are selected and created (partially) for giving birth to the kernels, and not (usually) for their own sake.

In the 2<sup>nd</sup> chapter of the 22<sup>nd</sup> ICMI study (Watson & Ohtani, 2015), C. Kieran, M. Doorman and M. Ohtani categorize theoretical frames into grand, intermediate-level, and domain-specific frames.

Our study aims at (re)constructing an intermediate-level framework, which we call the Theory of WPTs (TWPT), and links this to already established frameworks, such as the *anthropological theory of the didactic* (ATD) and its application, known as study and research paths (SRP) (Chevallard, 2007; Bosch & Gascón, 2014; Watson & Ohtani, 2015, pp. 260–272). The first step of theorizing will in a second step be analyzed through the lenses of ATD, where WPT is considered as part of the *technology* and *theory* elements of the studied *praxeologies* (Bosch & Gascón, 2014), which, similarly to SRPs, focuses on the connections between tasks (or questions). Therefore, considering ‘*distribution as a dilemma*’ in the categorization of design elements of tasks along 5 dilemmas by P. Sullivan, L. Knott and Y. Yang in the 3<sup>rd</sup> chapter of the 22<sup>nd</sup> ICMI study, both task-design approaches favour creating “doing mathematics” tasks (Watson & Ohtani, 2015, pp. 91–94).

The poster is to present a sample of a WPT (see Figure 1 below) linked preliminarily to the ATD, with tasks, solutions, and the analysis of the highlighted ‘kernels’ *yieldingness* and *invariant* (*quantities*). In Task B (Can you tell a power of 3 that ends with 127?), we do not need to consider divisions by  $10^3$ , it is enough (*yieldingness*) by its divisor, 8, as any power of 3 divided by 8 gives 1 or 3 as the *remainder*.

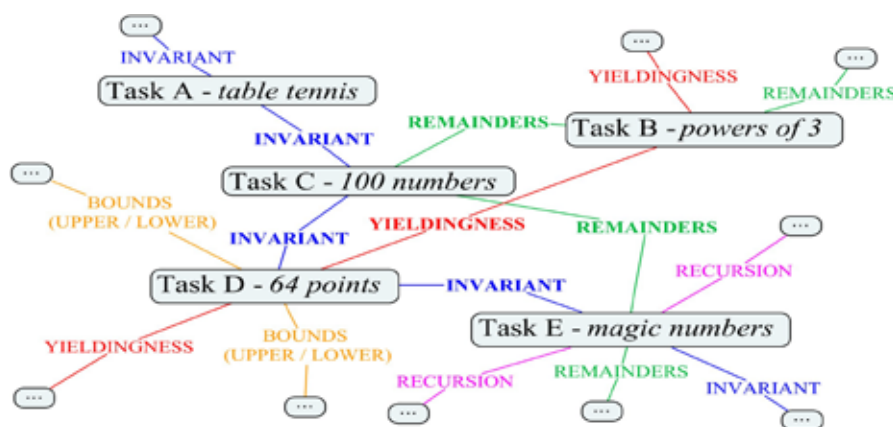

Figure 1: A sample of the Pósa WPT

Some other kernels in the TWPT are *experimentation*, *bounds* (upper and lower), *recursion* (*recursive thinking*), *induction*, and *proof of impossibility*. The collection and analysis of a (more) complete set of kernels is one of the main future goals of the present research.

# Secondary school mathematics teachers' selection and use of resources

Zeger-Jan Kock and Birgit Pepin

Eindhoven University of Technology, Eindhoven School of Education, the Netherlands;

[z.d.q.p.kock@tue.nl](mailto:z.d.q.p.kock@tue.nl)

*Keywords: Teacher resources, Secondary school mathematics, Survey.*

## Introduction

Secondary school mathematics teachers rely on multiple resources to select materials for classroom use, prepare lessons, and design their curriculum. These include traditional curriculum resources (e.g. textbooks), social resources (e.g. discussions with colleagues) and various digital resources, such as mathematics apps, e-textbooks (Pepin, Choppin, Ruthven, & Sinclair, 2017), and online platforms for sharing digital materials, and constructing lesson series and curricula (Gueudet, 2018). A plethora of digital resources have become available for teachers (Pepin & Gueudet, 2018). Understanding the role of resources in mathematics teachers' work may inform the design of (digital) resources and platforms. To foster this understanding knowledge about the actual use of the various resources is important. In the Netherlands, a survey on the use of learning materials has taken place periodically (Blockhuis, Fisser, Grievink, & Ten Voorde, 2016). However, this general survey does not focus on mathematics teachers and the specific combinations of resources they select.

In this exploratory survey study, we focused on the resources selected and used by secondary school mathematics teachers to prepare their lessons, including resources they use to find materials for classroom use (e.g. student tasks). The research question was: which kinds of resources are selected by secondary school mathematics teachers for lesson preparation, and what do they use them for?

## Theoretical framework: the lens of resources

In line with the documental approach to didactics (Trouche, Gueudet, & Pepin, 2018) we assume that teachers' use of resources has an impact on their teaching. Teachers look for resources, adapt them to their needs and arrange selected resources into learning sequences for their students. This *documentation work* is an essential characteristic of a teacher's work and takes place at the different levels: curriculum, lesson series, and (parts of) individual lessons. The types of resources used by teachers fall into different categories. Pepin and Gueudet (2018) distinguish (1) curriculum resources, (2) social resources, and (3) cognitive resources. Curriculum resources are "developed and used by teachers and students in their interaction with mathematics in/for teaching and learning, inside and outside the classroom". They are further categorized as (a) text resources (e.g. textbooks, syllabi, websites), (b) digital curriculum resources (e.g. e-textbooks, educational platforms), and other material resources (e.g. calculators, digital instructional technology). What distinguished digital curriculum resources from digital instructional technology is the possibility of arranging content and activities in line with the curriculum requirements. Social resources refer to human interactions, for example conversations with colleagues, or feedback from students. Cognitive resources refer, for example, to the mathematical frames and routines used by teachers, and are not considered in this study. By *use of resources*, we denote the selection of resources, their appropriation, and eventually modification by teachers to fulfill particular educational goals (e.g. determining mathematics content,

designing classroom activities or homework tasks). The results of a recent Dutch learning material survey show that textbooks and related materials have still been among the most important resources used by secondary school teachers independent of the subject, although teachers and school managers expect their importance to go down with time (Blockhuis et al., 2016). The most important digital resources for teachers are interactive student exercises. Teachers have indicated that they need guidance, particularly in selecting digital resources.

## Method

A survey was administered in June/July 2018 to secondary school mathematics teachers, who were invited to participate by means of a brief text and a link in an electronic newsletter<sup>1</sup>. We received 78 complete responses from mathematics teachers. The survey consisted of 14 questions and was partly based on a survey on digital resources for teachers in France (Gueudet, 2018). Items included, among others, teacher background information; (digital) resources selected to prepare lessons; the purpose of the selected resources; and classroom material retrieved or adopted from digital resources.

## Results and conclusion

The survey results indicate that the most widely used resources for lesson preparation were national documents (e.g. syllabi), teachers' own notes, interactions with colleagues, mathematics apps, and the website belonging to the textbook. General educational platforms and social media were mentioned least often. Resources were mostly consulted to find materials for classroom activities, although interactions with colleagues covered all aspects of lesson preparation. In terms of digital resources, Geogebra was mentioned most often, followed by a digital version of the textbook with its associated website, and online video clips. Least often, general educational platforms were used, in which teacher could create and share materials, in spite of efforts to promote these platforms and their transformative potential (Pepin et al., 2017). It appears that the mathematics teachers were mostly led by the school's mathematics textbook and its associated (digital) materials.

# Multiplicative reasoning task design with student teachers in Scottish schools: valuing diversity, developing flexibility and making connections

Helen Martin

School of Education, University of Aberdeen, Scotland; [h.martin@abdn.ac.uk](mailto:h.martin@abdn.ac.uk)

*Keywords: multiplicative reasoning, teacher education, task design.*

## Introduction

The aim of this poster is to present the development of a synthetic landscape of multiplicative reasoning constructed by student teachers. It explores the implications of working in a way that integrates literature from three different perspectives: maths recovery (MR), cognitively guided instruction (CGI) and realistic mathematics education (RME). The aim is to better understand how working in this way affects the way student teachers interact with learners, the questions they ask, the tasks they design: their capacity to value diversity in literature and develop their flexibility in practice.

There is a pattern of superficial adoption of findings from research in teaching mathematics in Scottish schools that often relies on dissemination of a product where teachers have not been a part of the process of constructing understanding. This often leads to a series of short lived interventions that rarely produce the positive effects expected. In which case, what can we use within teacher education to inform ourselves, our student teachers, our professional colleagues that accepts the natural dilemmas of teaching and might improve professional and ethical decision-making in an ever-increasing political world of curriculum design and change?

To address this question the author alongside a teaching colleague developed and have redeveloped a year 3 undergraduate mathematics education course over the past four years to consider how to better support student teachers entering this environment. They need to be able to adapt quickly to changing priorities using informed professional decision-making. To create the space and time to think more slowly, the course focuses on the key shift in thinking from additive to multiplicative reasoning. The first semester explores additive reasoning working with children aged 4–7 years old and the second semester focuses on multiplicative reasoning working with children aged 8–12 years old. Each semester consists of six 3-hour sessions followed by five weeks in a school. This poster uses the second semester course where the assignment requires student teachers to report on their analysis of the children's multiplicative reasoning.

## Theoretical Background

Rather than taking one piece of major research and focusing on this to the exclusion of others we looked at using several significant studies. In this study, alongside the formal curricular guidelines in Scotland, Curriculum for Excellence (Scottish Government, 2009), three different theoretical perspectives are used: Realistic Mathematics Education (Fosnot & Dolk, 2001), Cognitively Guided Instruction (Carpenter, Fennema, Franke, Levi & Empson, 2015) and Maths Recovery (Wright, Ellemor-Collins & Tabor, 2012). The course is designed to consider the benefits and limitations of each in a complementary rather than a competitive manner. It is by synthesizing ideas from different

perspectives that have different foci that student teachers can become much more aware of the similarities and differences: complementary strengths and non- overlapping weaknesses. Similarly, the sessions include tasks focused on student teachers as learners of mathematics, researchers and teachers of mathematics to build a sense of themselves as mathematicians, researchers and teachers.

## Methods

This design research (Gravemeijer & Cobb, 2006) takes an iterative approach to studying and refining task design within a mathematics education classroom: to develop our understanding of the embodied process of developing theory *through* practice and the means that are designed to support that learning. The design principles are based on mathematics as a constructive activity (Watson & Mason, 2005) with an emphasis on mathematical practices and a more participatory view of learning and teaching mathematics.

This poster will illustrate the latest cycle of this design research using multimodal data provided by the most recent cohort of 38 students during academic session 2017/18: student teacher's assignments, planning documents, videos and transcripts of task-based interviews with children and images of child jottings to better understand how the design of the course influences the tasks designed by student teachers.

## Findings

Preliminary findings indicate that most student teachers have shifted their focus to a more participatory view of learning mathematics, discussing a range of strategies and models used by the children. Some of the student teachers take informed risks, experiment with different pedagogical approaches and are beginning to design their own tasks however very few student teachers understood the underlying structure of number strings (Fosnot & Dolk, 2001).

# **Comparison of Japanese and Turkish textbooks: Giving opportunities for creative reasoning in terms of proportion**

Yasin Memiş

Anadolu University, Turkey; [yememis@anadolu.edu.tr](mailto:yememis@anadolu.edu.tr)

*Empirical research indicates that students, when solving tasks, frequently use superficial similarities to find the right algorithm. Furthermore, mathematics textbooks continue to use a teaching design that supports rote learning. This kind of approach creates difficulties in terms of promoting proportional reasoning as well as other mathematical skills. The purpose of this study is to examine the extent to which selected Grade 7 Japanese and Turkish textbooks provide opportunities to use creative mathematical reasoning, in terms of proportion topics. The results imply that proportion topics in the selected Turkish textbook mostly design opportunities for students to use algorithmic mathematical reasoning. However, Japanese textbook provides more creative mathematical reasoning opportunities.*

*Keywords: Mathematical creative reasoning, proportional reasoning, textbook analysis.*

## **Introduction**

Proportional reasoning is a very important skill that students must acquire in middle school. The National Council of Teachers of Mathematics (NCTM) (2000) has highlighted that proportional reasoning should be “an integrative theme in the middle grades mathematics program” (p. 212). Being able to reason proportionally, on the one hand, plays a key role in the meaning of many mathematical content areas (e.g. similarity, trigonometry, probability), while at the same time constituting the basis of the concepts (e.g. speed, density) often encountered in real life (Lesh, Post, & Behr, 1988). However, most students struggle with developing proportional reasoning, and one of the reasons for this failure is related to weak teaching-design methods. Typically, a textbook on the subject of ratio and proportion starts by showing the different ways of writing the ratio, and the proportion is defined as two equal ratios. Then, students usually focus on finding answers to similar questions in the cross-multiplication algorithm. Students frequently decide that a task involves a proportion following superficial cues such as, “the problem gives 3 numbers, and 1 other number is missing”. When solving this type of proportion task, students only need to recognise the task, insert the relevant numbers, and perform the calculation (Labato & Ellis, 2010). In this process, only the result is important; students do not usually concern themselves with proportional reasoning. The correct solution to this kind of example or task used by students is insufficient to show that a degree of proportional thinking has occurred at the desired level. The repetition of similar questions will allow for more practice of multiplication and division rather than improving proportional thinking. Furthermore, the continuance of such algorithmic questions will result in the student not being sufficiently educated about the multiplicative relationship required for proportional thinking. Instead, situations in which students create their own solutions will provide opportunities for them to connect with previous information and, in particular, allow them to improve multiplicative thinking (Labato & Ellis, 2010).

Unfortunately, this kind of instructional design that uses highly algorithmic tasks is presented in the textbooks. Textbooks frequently provide questions that are similar to each other, and students are

expected to engage in solving them (Boesen, Lithner, & Palm, 2010; Hiebert, 2003). Studies also show that students who decide on which algorithm to use when solving a problem with superficial evidence usually try to remember the algorithm and then try to find the result (McNeal, 1995; Kamii & Dominick, 1997). This situation is similar to proportional reasoning in Turkish and other countries' textbooks. The research indicates that proportional reasoning tasks in various countries' textbooks are mostly low-level and contain highly familiar routine problems (da Ponte & Marques, 2007; İncikabı & Tjoe, 2013). Learning to reason proportionally takes effort and time, and in addition to routine problems, non-routine problems are also needed to help students develop. The algorithms presented without letting students create the ideas they need will not provide them with opportunities to improve their proportional reasoning skills (Labato & Ellis, 2010).

Textbooks play a key role in many important areas, such as teaching design and student achievement. Since mathematics textbooks are a bridge between students and teachers, it could be said that textbooks are effective tools that offer students learning opportunities (Rezat, 2006). Due to this important role of the textbook, it could be considered as a mediator between the intended and the implemented curriculum (Schmidt, McKnight, & Raizen, 1997), and therefore, textbooks are important research areas in terms of mathematics education. Due to the important roles of textbooks and proportional reasoning, it is possible to find both national (Bayazıt, 2013; Dole & Shield, 2008) and cross-national studies (da Ponte & Marques 2007; İncikabı & Tjoe, 2013). Although there are studies on how the Turkish reform curriculum handles mathematics education, studies about how to design the contents of proportional reasoning in textbooks are very limited. For this reason, this cross-national study will make an important contribution to those who prepare education programmes, as well as textbook authors.

The aim of this research is to compare the extent to which selected Grade 7 Japanese and Turkish textbooks provide opportunities for creative mathematical reasoning in terms of proportion.

The two central research questions in this investigation are as follows:

1. To what extent does the teaching design of selected Japanese and Turkish textbooks support the development of creative reasoning in the chapters on proportion?
2. What kind of reasoning is expected from students for solving the tasks presented in the textbooks?

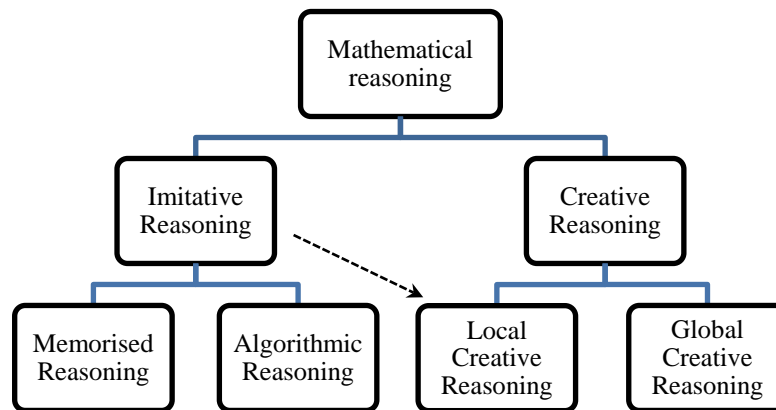

## Conceptual framework

Algorithms are important components in mathematics education; however, algorithms presented to students without preparing an adequate background prevent the development of mathematical skills. The students will use the algorithms they have learnt to solve the questions that they classify as superficial. This process, like any mathematical skill, will prevent the development of the desired level of proportional thinking (Labato & Ellis, 2010). Lithner's framework of mathematical reasoning types sets apart algorithmic and creative reasoning, and so it could present a different perspective that examines the extent to which textbooks promote the development of proportional reasoning.

In this study, Lithner's framework of mathematical reasoning types will be used (Lithner, 2008), which was first created as a result of empirical studies in the field (Bergqvist et al., 2007; Lithner,

2004, 2008). Throughout those studies, reasoning was defined as “the line of thought adopted to produce assertions and reach conclusions in task-solving” (Lithner, 2008, p. 257).

Lithner (2008) identified two main reasoning types: Imitative Reasoning (IR) and Creative Reasoning (CR). The main distinction between these two reasoning types is that IR can be identified as copying a solution process or as using an algorithm directly from a source example or from a textbook narrative, whilst CR creates a product from a creative mathematical thinking process (Figure 1).

**Figure 1: An overview of Lithner’s (2008) mathematical reasoning framework**

There are two other forms of reasoning that fall under the category of IR, which are Memorised Reasoning (MR) and Algorithmic Reasoning (AR).

MR is characterised by the idea that “the strategy choice is founded on recalling a complete answer, the strategy implementation consists only of writing it down” (Lithner, 2008, p.258). An example of this is writing a proof step that has already been memorised. The AR sequence should function as follows: “the strategy choice is to recall a solution algorithm. The remaining reasoning parts of the strategy implementation are trivial for the reasoner, only a careless mistake can prevent an answer from being reached” (Lithner, 2008, p. 259).

CR can also be separated into two sub-categories: Local Creative Reasoning (LCR) and Global Creative Reasoning (GCR).

LCR contains major parts of IR (e.g. recalling facts and using algorithmic sub-procedures), and minor parts of CMR. This means that a LCR task solution is always based on algorithms, although the student needs to modify the algorithm locally in a “non-trivial” way. A GCR task does not have a solution that is based on an algorithm, and therefore requires CR throughout the whole task-solving process. GCR may contain construction of an example, proof of something new, or modelling (Bergqvist et al., 2007).

CR fulfils the following three properties:

1. “Novelty: a new (to the reasoner) reasoning sequence is created or a forgotten one is re-created”.
2. “Plausibility: there are arguments supporting the strategy choice and/or strategy implementation motivating why the conclusions are true or plausible”.

3. “Mathematical foundation: the arguments are anchored in intrinsic mathematical properties of the components involved in the reasoning” (Lithner, 2008, p. 266).

For the analysis of this study, textbooks will be examined as having two main parts: the tasks and examples provided to the students. In this study, a mathematical task is defined as a question that requires a solution from students, whilst an example is defined as a question that is given with an appropriate solution or solution process.

## Method

Japanese and Turkish textbooks were selected for this study. The reason for this choice is primarily the success of Japanese students in international examinations, such as Trends in International Mathematics and Science Study (TIMSS). The 2015 TIMSS results saw 15-yearold Japanese students ranked 5<sup>th</sup>, and Turkish students ranked 40<sup>th</sup>, in terms of mathematics performance. The results of the 2015 TIMMS for Grade 8 students on the topics of “ratio, proportion and percent” emphasised the difference between the achievements of students from these countries. In response to questions within this study, 67% of Japanese students got the correct answers, compared with just 34% of Turkish students.

The textbooks that have been chosen for analysis in this study are Mathematics International Grade 7 (Fujii & Matano, 2012), published by Tokyo Shoseki, and Mathematics Textbook Grade 7 (Bilen, 2017), published by Gizem in Turkey. These two textbooks were passed through an approval process by their respective governments for use in classrooms in these two countries. The Tokyo Shoseki series, which has been translated into English, has a big market in Japan (Miyakawa, 2017). For the purpose of this study, only the proportion chapter was examined. The proportion topic is included in the Grade 7 textbook in both countries. In the Grade 7 Turkish textbook, the chapter on proportion is presented with two subdivisions, including nine examples and ten tasks. In the Grade 7 Japanese textbook, there were only three examples and 18 tasks in the proportion chapter.

The examples and tasks were examined for analysis and were classified according to mathematical reasoning frameworks. Although the CR process is similar to the solution structure of non-routine problems, the framework is more focussed on the distinction between imitation and creation (Lithner, 2017). For this reason, templates and solutions were considered. If the example/task could be solved with previous algorithms without any modification, they were classified as AR, whilst if the example/task could be solved with previous solution processes yet needed some modification to this process, they were classified as LCR. However, if the example/task did not have a solution that was based on an already-given algorithm and required CR throughout the whole solution process, it was classified as GCR.

Figure 2 shows two examples from the Grade 7 Turkish textbook in the proportion chapter. These examples were classified as AR, as they present a teaching design that simply requires replacing the appropriate numbers in the template solutions in order to do the calculations correctly.

<p><b>ÖRNEK</b></p> <p>Bir piring pilavı tarifinde 2 bardak pirinç 3 bardak su konuyorsa 1 bardak pirinçe kaç bardak su konması gerektiğini bulalım.</p> <p><b>ÇÖZÜM</b></p> <p>Pirinç miktarının su miktarına oranı <math>\frac{2}{3}</math>'tür. 1 bardak pirinçe konulacak su miktarı <math>x</math> bardak olsun.</p> <p>pirinç miktarı <math>\frac{2}{3} = \frac{1}{x}</math> → pirinç miktarı su miktarı <math>x = \frac{3}{2} = \frac{3 \cdot 2}{2 \cdot 2} = \frac{1 \cdot 6}{1} = 1,5</math> bulunur.</p> <p><b>ÖRNEK</b></p> <p>50 mL'lik limon kolonyasının 12 tanesi 15 TL olduğuna göre 50 mL'lik 1 limon kolonyasının kaç lira olduğunu bulalım.</p> <p><b>ÇÖZÜM</b></p> <p>50 mL'lik 1 limon kolonyasının fiyatı <math>a</math> lira olsun.</p> <p>kolonya sayısı <math>\frac{12}{15} = \frac{1}{a}</math> → kolonya sayısı <math>a = \frac{15}{12} = \frac{15 \cdot 12}{12 \cdot 12} = \frac{1 \cdot 25}{1} = 1,25</math> TL bulunur.</p>	<ol style="list-style-type: none"> <li>1. You need 2 cups of rice and 3 cups of water to cook rice. In this case, how much water is needed for 1 cup of rice?</li> <li>2. 12 small bottles of 50ml cologne costs 15 TL. If you want to buy 1 small bottle of 50ml cologne, how much would it cost?</li> </ol>
-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Figure 2: Grade 7 Turkish textbook examples (p.127)

There are five tasks at the end of the chapter, which students are required to solve. However, to complete these tasks, they only need to remember the previous solution process. Students need to replace the numbers in the template and perform basic calculations to obtain the solution. For this reason, the task below (in Figure 3) is classified as AR.

<p>1) 3 yolcu otobüsünde 132 koltuk varsa aynı tür 1 yolcu otobüsünde kaç koltuk vardır?</p> <p>A) 44      B) 45      C) 46      D) 48</p>	<p>1) If 3 buses have 132 seats, how many seats are there in 1 bus?</p>
--------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------------------

Figure 3: Grade 7 Turkish textbook task (p.128)

The task below (in Figure 4), taken from the Japanese textbook, was determined to be of the LCR type. There are no similar tasks from previous examples, and so students cannot solve them by directly using cross multiplication algorithms ( $a:b=c:d$ ); instead, they need to carry out local modifications to the previous solution methods ( $160+4x:60+3x=2:1$ ).

**Let's Try**

There are two water tanks, A and B. In tank A, water is poured continuously at 4L per minute, and in tank B, 3L per minute of water is being poured.

At 10:00, when the amount of water was measured, there were 160L of water in tank A and 60L of water in tank B.

(1) What time will it be when the amount of water in tank A will be twice as much as the amount of water in tank B?

Figure 4: Grade 7 Japanese textbook task (p.112)

The example below (in Figure 5), taken from the Japanese textbook, was determined to be GCR. This example investigates whether “3: 4 = 6: 8” is true. There is an argument given that “if  $a: b = m: n$  then  $a \cdot n = b \cdot m$ ”, and it is then proved using mathematical foundations. Finally, the example presents a generalisation, which provides the student with a totally new creative process with regards to the proofing argumentation.

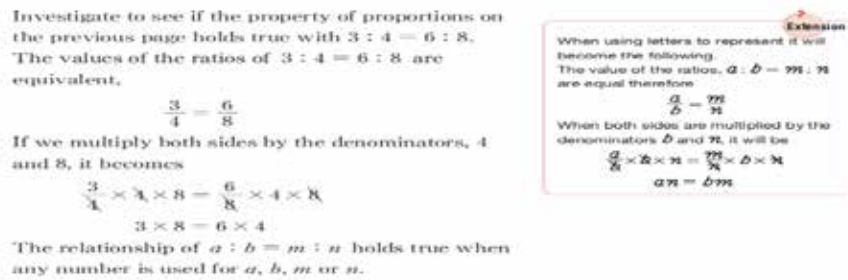

Figure 5: Grade 7 Japanese textbook simple example (p.99)

## Results

In this chapter, the pilot study results of the classified mathematical reasoning types in the proportion chapters in Turkish and Japanese textbooks are presented (Tables 1 and 2).

	Example	Task	Total
MR	0	0	0
AR	9	10	19
LCR	1	0	1
GCR	0	0	0
IR (MR + AR)	9	10	19
CR (LCR + GCR)	1	0	1

Table 1: Classification of tasks and examples in the Turkish textbook

	Example	Task	Total
MR	0	0	0
AR	2	11	13
LCR	0	6	6
GCR	1	1	2
IR (MR + AR)	2	11	13
CR (LCR + GCR)	1	7	8

Table 2: Classification of tasks and examples in the Japanese textbook

The first conclusion drawn from the report of the study is that the Turkish textbook features no GCR-type tasks or examples, and furthermore, ten of the tasks within the chapter do not even require any CR reasoning. These results show that the Turkish textbook only provides limited and weak opportunities for students to perform CR. In addition, the Turkish textbook's teaching style mostly shows the necessary algorithm for solving a specific task within the examples, which means that when the students are solving the tasks at the end of the chapters, these algorithms can be used directly. This type of teaching style mostly supports IR, especially AR. In contrast, within the Japanese textbook's proportion chapter, there is a total of three examples. Two of these examples are classified as AR, and the other example is classified as GCR. There are 18 tasks for the students to solve, with seven of these tasks requiring CR. This result reveals that the Japanese textbook provides more, and stronger, opportunities for CR than the Turkish textbook in the proportion chapter.

## Discussion

The development of proportional thinking is a milestone for students, especially for those who take many years to progress. In this process, students will be supported by different problem-solving situations as much as possible, to support healthy development. The mathematical reasoning framework has shown that the Grade 7 Turkish textbook mostly provides opportunities for AR only in terms of learning proportion, in contrast to the Grade 7 Japanese textbook.

Algorithms have an important place in mathematics, as they are an effective solution to a general class task. There are short-term gains and benefits, such as the ‘quick response to tasks’; however, AR can be a barrier to obtaining effective skills that can be used in the long term. Using algorithms in proportional reasoning can create the same problem. A teaching design based solely on using algorithms will, in the long term, allow students to solve familiar tasks that they recognise as only being superficial. The fact that students are engaged in different problem situations that require CR will lead them to understand the components of proportionality (multiplicative thinking, absolute thinking, etc.) in greater depth. Proper use of CR in the textbooks would contribute to the solution of this problem and should enable further development of students’ mathematical ability. The results of this study offer useful information on content design for educators, especially textbook authors. Applying the process should provide teachers with insights into the strengths and weaknesses of the textbooks being employed and enable them to make effective decisions about the selection and use of textbooks. In future studies, the comparison of different book series from different countries will provide new data that could be used to evaluate the results of the study in a wider context.

## Introduction

Despite its importance, mathematics is often perceived as boring and difficult. The demand for exciting mathematical experiences resulted in the Netherlands in a yearly event called the ‘Big Maths Day’ (Abels et al., 2016). During such a day, pupils are not taught their usual curriculum: instead, they are involved in playful mathematical activities. In this report, we present selected results from a study that involved the design and implementation of a ‘Maths Day’ (‘MD’) in a Greece.

## Theoretical Background

The MD activities were designed drawing on ‘Realistic Mathematics Education’ (‘RME’) and ‘Inquiry Based Learning’ (‘IBL’). According to RME, teaching mathematics should be a process of ‘guided reinventing’ (Freudental, 1991). Pupils, guided by their teacher, reinvent and construct mathematics concepts from meaningful situations. Such reinvention can be successful, when it is based on ‘inquiry’. ‘Inquiry based learning’ is an educational approach, which is ‘driven more by a learner’s questions than by a teacher’s lessons’ (p. 1, EDC, 2016). Pupils try to find the answers they are looking for, by working in groups, on meaningful activities guided by their teachers.

## Methodology

The Greek MD took place in a primary school located in the capital of Greece, Athens. Different mathematical activities were planned for different classes. This report focuses on the 3rd and 4th year classes, which consisted of 34 pupils with an age span of 8-10 years. Their day was labelled ‘Amusement Park’ and consisted of three parts: the ‘Introduction’, the ‘Circuit Form’ and the ‘Open Problem’ activities. The pupils were divided in six groups and were guided by four researchers/teachers. Data were collected from observations and interviews. Results from one group of pupils working and on a ‘Circuit Form’ activity called the ‘Fear Room’ will be presented below.

## Results

The ‘Fear Room’ activity is essentially a variation of the board game ‘Snakes and Ladders’. A giant board is set up on the floor, made of A4 paper sheets with the numbers 1 to 40 written on them (Figure 1). There are ‘traps’ (the sheets with the plastic snake, bat and spider on them) and ‘bonuses’ (the sheets with small colourful papers on them). Two opponent teams would play the game each time. One member from each team would be chosen as a ‘pawn’. There was a stack of cards from which each team had to choose one every time they played. Each card ‘ordered’ the players to perform a combination of mathematical operations. The players had to choose numbers for the selected

operations. The aim of the game was to come up with a result that would lead them to a ‘bonus’ rather than a ‘trap’. The learning objective of this activity was ‘tackling mental calculations with numbers up to 100’.

**Figure 1: A team playing in the ‘Fear Room’**

Initially, the group that we focus on, encountered difficulties with the calculations. Nevertheless, as the game went on, they got used to the procedure of finding the right operations and the right results. All the pupils emphasised that they liked this game and that the funniest part of it was ‘being a pawn’.

## Conclusion

The ‘Fear Room’ activity provoked ‘inquiry based learning’ and on the same time the pupils perceived it as ‘a very funny game’. Such findings indicate that mathematics-despite its ‘bad’ reputation as a difficult and boring subject can become interesting and appealing when it is enriched by ideas from RME and IBL.

## Acknowledgments

1. We would like to gratefully acknowledge the financial support of the Department of Education of the National and Kapodistrian University of Athens for this project.
2. We would like to thank Barbara Douka, Marianna Bikini, Simos Pasinios and Maria Sanida for participating in the design and implementation of the ‘Maths Day’.

# Examination of mathematical opportunities afforded to learners in grade 1 Malawian primary mathematics textbooks

Lisnet Mwadzaangati

University of Malawi, Faculty of Education, Malawi; [lmwadzaangati@cc.ac.mw](mailto:lmwadzaangati@cc.ac.mw)

*This paper present findings from a study which aimed at examining mathematical opportunities available in Malawian grade 1 textbook and their ability to enhance learners' understanding of number concept through outcome based education (OBE). Two elements (examples and tasks) of the Mathematics Discourse in Instructional analytic framework for Textbook Analysis (MDITx) were used to guide analysis of the textbook. The results show that the textbook has provided learners with mathematical opportunities to understand the number concept using different levels of examples which are presented with real life graphics. However, lack of variety in terms of the tasks provided in the textbooks is viewed as a limiting factor to enhancing learners' understanding of number concepts through independent practice and critical thinking, hence not achieving some of the goals of OBE.*

*Keywords: Mathematics textbook, number concept, examples, tasks, outcome based education.*

## Introduction and background.

The results of Southern and Eastern Africa Consortium for Monitoring Education Quality (SACMEQ) show that Malawian pupils consistently perform very poorly on primary mathematics especially in number concept and operations (SACMEQ, 2011). For example SACMEQ 1 and 3 project results showed that Malawian grade 6 learners achieved poorly in numeracy, specifically in number concept and operation as compared to the other Southern African Countries (SACMEQ, 2011). Kasoka, Jacobsen and Kazima (2017) bemoans the Malawi SACMEQ results as worrisome because number concept and operations define numeracy. This implies that it might be difficult for Malawi to improve numeracy levels which are very low among its citizens if the causes of learners' inability to understand number concept and operation are not addressed.

As one way of addressing the problem of learners' low achievements in mathematics and science, the Government of Malawi through the ministry of education proposed a shift from objective education model (OEM) to outcome based education model (OBE). The underlying argument for the shift was that OEM was teacher centred, hence teacher played a more active role in achieving learning objectives than the learners. As such, OBE was assumed to be a major solution to improving and promoting learners' active participation and performance in all school subjects including mathematics (Malawi Institute of Education [MIE], 2006). The Malawi OBE curriculum emphasises learners' achievement through active participation in classroom and out of classroom activities which promote independent learning and critical thinking. In OBE, the content and focus of the curriculum determines the content and structure of curriculum material including textbooks, hence the value of a textbook is determined by the degree to which it contributes to students' achievement of the learning outcomes (Chang & Salalahi, 2017). This means that the goals of OBE curriculum are expected to be highlighted and achieved through the textbook. As Fujita, Jones and Kunimune (2009) argue, textbooks constitute much to curriculum implementation, hence they are widely used due to their

potential in mediating between the intended and the implemented curriculum. This implies that studying of textbooks is important because of their influence to both teachers and learners. However, since the implementation of OBE curriculum in Malawian primary education, no study has been conducted to analyse the content of the textbooks and their affordances in learners' achievement of the learning outcomes and OBE goals. As such, the purpose of this study was to analyse the effectiveness of the content of grade 1 primary mathematics textbooks in helping the learners to achieve intended learning outcomes. Specifically, the study aimed to answer the following questions:

1. What opportunities are available for Malawian grade 1 learners to learn number concept from primary school mathematics textbook?
2. How do opportunities to learn number concept in the textbooks relate to the goals of outcome based education curriculum?

This study is timely in Malawian context for effective achievement of OBE curriculum goals. The study also makes relevant contribution to global literature on textbooks as there are fewer topic specific studies on mathematics textbooks analysis (Chang & Salalahi, 2017).

### **Theoretical framework**

Ronda and Adler (2016) proposed a framework for analysing mathematics textbooks which is known as Mathematics Discourse in Instructional analytic framework for Textbook analysis (MDITx). The MDITx tool was adapted from Mathematical Discourse in Instruction (MDI) framework which was developed to analyse opportunities available for learners to learn mathematics (Ronda & Adler, 2016). MDITx is rooted from the sociocultural perspective that foregrounds the importance of mathematics in a coherent manner. MDITx comprises of five key elements; object of learning, examples, tasks, naming/word use and legitimations. The object of learning is the main focus of the lesson (Adler & Ronda, 2015). The object of learning might contain the key content (mathematical concept) as well as the expected capability (like simplifying, solving or proving). Examples are particular case of a larger class used for drawing reasoning and generalisations (Ronda & Adler, 2016). Learners' textbooks are expected to contain examples which would enable learners to attend to understand a particular object of learning. The examples might be worked (to illustrate the procedure), or not worked (as learners' exercise). Tasks are what learners are asked to do with the examples like solving or drawing (Ronda & Adler, 2016). Different examples and tasks offer learners different opportunities to learn mathematics. Naming/word use is the way of naming mathematical concepts and procedures. Ronda and Adler (2016) argue that the way we name mathematical concepts and procedures might affect learners' focus during the lesson. Legitimations are the mathematical concepts and mathematical criteria communicated to legitimise or justify key moves or steps in a procedure.

Analysis of the textbooks focused on two elements of MDITx which are examples and tasks. The study focused on examples and tasks because it is commonly assumed that examples and tasks play a central role in the development of mathematics as a discipline (Olteanu, 2018). The second reason for choosing examples and tasks was that at this level, the learners have not reached the level of reading, as such, there would be little naming/word use and legitimisation in the grade 1 textbook. MDITx framework was suitable for analysing number and operations topic because its elements are

similar to characteristics of OBE. As already explained, OBE emphasises on achievement of learning outcomes and measures the learners' achievement using examples and tasks. Furthermore, OBE defines learning outcomes as what learners are supposed to learn. This definition is similar to that of object of learning in the MDITx framework.

## Methodology

I analysed grade 1 mathematics textbook for learners by the Malawi Institute of Education publisher. This is the only textbook available for use by Malawian grade 1 learners. The minimum age for grade 1 learners in Malawi is 6 years. According to the OBE mathematics curriculum, learning outcomes for the units of number and operation in grade 1 are; count up to 9, identify and write numbers up to 9, add numbers with sum not exceeding 9, subtracting of numbers within the range of 0 to 9, apply number concept in daily life. In my textbook analysis, I only focused on Unit 1 and Unit 4 which are about counting and writing of numbers 0 to 9. This is because ability to count and write these numbers is a foundation for understanding other mathematical operations. As Aunio and Niemivirta (2010) argues, learners understanding of number concept is very important in the learning of mathematics, hence learners without sound understanding of number concept skills struggle to excel in learning mathematics. Table 1 presents a summary of the codes that I used to analyse the examples and the tasks as adapted from Ronda and Adler (2016).

Examples	Tasks
Level 1-at least one of the pattern of variation (C-Contrast, G-Generalisation, F-Fusion).	Level 1-carry out the known procedure or use known concepts related to the object of learning (KPF only).
Level 2- any two of C, G, or F	Level 2-carry out procedures involving the object of learning (includes current topic procedure-CTP).
Level 3-all the patterns of variations.	Level 3-Carry out level 2 tasks plus tasks that involve multiple concepts and connections (includes CTP and Application/making connections-AMC)

**Table 1: codes for analysing textbook examples and tasks**

Example space belonged to Level 1 if only one pattern of variation is used throughout (the examples were the same), or Level 2 if there was contrasting (there was variations which signified two aspects of object of learning), or Level 3 if there was fusion of more than one aspect of the object of learning (single pattern as well as contrasting examples present). A task belonged to Level 1 if it only involved Known Procedure Facts (KPF) from previously learned knowledge, or to Level 2 if it involved the current topic procedure (CTP) or required learners to apply the procedure that is being introduced in the current lesson, or to Level 3 if it included the current topic procedure as well as Applications/ Making Connections (AMC) among different concepts.

## Results and discussion

Table 2 presents a summary of the findings from analysis of the examples and tasks from unit 1 to unit 4 of the grade 1 learners' mathematics textbook.

Unit	Object of learning	Examples	Tasks
1	Counting and writing numbers up to 5 (25 example spaces)	G (11 example spaces) C (8 example spaces) F (6 example spaces)	KPF (5 tasks) CTP (18 tasks) AMC (2 tasks)
4	Counting and writing numbers up to 9 (15 example spaces)	G (6 example spaces) C (4 example spaces) F (5 example spaces)	KPF (4 tasks) CTP (9 tasks) AMC (2 tasks)
	Legend	G: generalisation C: Contrast F: Fusion	KPF: Known procedure and facts CT: Current topic and Procedures AMC: Application/making connections

**Table 2: summary of nature of examples and tasks in grade 1 learners' mathematics textbook**

Column 1 indicates textbook units where learners are introduced to number concept in the grade 1 learners' textbook. Column 2 indicates the objects of learning under each of these units. Column 3 indicates codes assigned to example spaces under each unit. Column 4 indicates the codes assigned to learners' tasks against each unit. The table shows that out of the 40 example spaces, 17 example spaces belonged to level 1 (G) as they required same ways of either counting or identifying numbers. This implies that more examples leaned toward generality of numbers through noticing of similarity. 12 examples belonged to level 2 (C) as they required different demands like identifying what a particular number concept is and what it is not. 11 example spaces belonged to level 3 (F) because they contained examples which required understanding of different learning outcomes like counting, identifying numbers and writing numbers. This implies that most example spaces contained one pattern of variation (generalisation or contrasting) and few had a combination of different patterns of variation (fusion). This means that the textbook offers few opportunities for learners to achieve several outcomes in a single example space.

Analysis of the tasks showed that out of the 40 tasks, 27 tasks were under CTP as they required learners to use knowledge of the number concept that was being learnt. 9 tasks were under KPF as they required learners to use their previous knowledge of counting. 4 tasks were under AMC as they involved comparing the magnitude of different numbers (ordering of numbers in either ascending or descending order). This shows that the 2 units mainly contained level 2 (CTP) tasks. This implies that most of the tasks aimed at mediating learners' capabilities with respect to the current topic (Ronda & Adler, 2016). Table 3 present figures which show example spaces and tasks presented in the textbook with an aim of mediating meaning of number 1 concept.

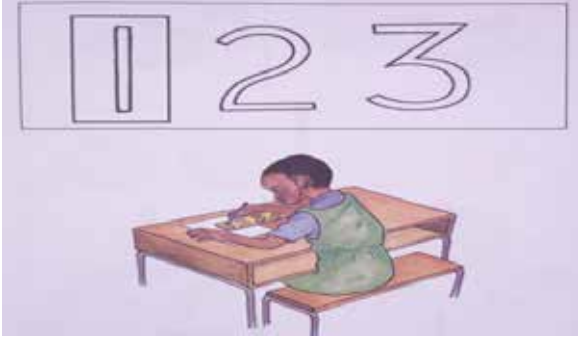

Example space	Description of the task
 <p>Figure 1: counting number of objects</p>	<p>Count the number of objects in each box.</p>
 <p>Figure 2: identifying of boxes with 1 object</p>	<p>Identify boxes containing 1 object.</p>
 <p>Figure 3: drawing number 1 using a model</p>	<p>Drawing number 1 using a model.</p>
 <p>Figure 4: counting and writing number 1</p>	<p>Counting and writing the number of objects in each box</p>

Table 3: examples spaces and tasks

## Discussion on the example spaces

The figures in table 3 provide a general layout on example spaces and tasks provided in units 1 and 4 of the textbook. These are the units which introduce learners to number concepts from 0 to 9. The task and the object of learning for learners textbooks for grade 1 to 4 are in local language as per the education system in Malawi. The study found that both units introduced the numbers in a similar manner. Firstly, each unit started with an example space for counting of objects. Secondly the unit presented an example space for identifying objects of a specific number. Thirdly the unit presented an example space for drawing number 1 using drawing materials. Lastly the unit presented example space for counting and writing number of objects.

I coded example space in figure 1 under generalisation (G) because there is one object in each box, hence representing number 1. As such the examples in figure 1 were coded under generalisation because they enable learners to generalise that number 1 represent single object. This also implies that the example space only focused on single outcome of counting number of objects, hence it is at low level (level 1). I coded example space in figure 2 under contrasting (C) because there are different numbers of objects in each box. This means that the learner has to make similarities and contrasts between or among number and objects when identifying boxes containing only 1 object. In so doing the learners understand the difference between objects used to represent the number 1 and those which do not represent the number 1. This shows that example space in figure 2 is at medium level (level 2). I coded an example in figure 3 under G because it was only about drawing a number 1. This means that the aim of the example in figure 3 was to help learners to have a general picture of how the number 1 can be drawn. As such the example in figure 3 is at low level (level 1). I coded example space in figure 4 under Fusion (F) because it contained 2 learning outcomes which are counting number of objects and writing number 1. This means that the example space in figure 4 is at higher level (level 3).

I found that example spaces in units 1 and 4 provided learners with opportunities to understand number concepts properly because they mediate the learning outcome and real life visual features. For example, example spaces in figures 1, 2 and 4 contain pictures of a girl, book, bicycle, fish, house, money, tomato, pencil and so on. These are real like features which are familiar and used by the learners in their daily life. This implies that these features would enhance learners' understanding of the number concept. Therefore the most important feature in both units of the textbook is that they are dominated by real life graphics, hence they can help the learners to understand the number concepts. As Olteanu (2018) argues, learners' understanding of mathematical concepts is visually mediated through diagrams, graphs, and drawings.

## Discussion on the tasks

The learning outcome for figure 1 task is counting number 1, and the accompanying task is about counting the number of objects in each box. I coded this task under current topic procedures (CTP) because it is mainly related to the current learning outcome. The learning outcome for figure 2 is identifying number 1 concept and the accompanying task is to identify boxes containing 1 object. I coded this task under applications/making connections as it offers learners opportunities to further understand the number 1 concept through making of judgment about what it should contain and what

it should not contain. The task for figure 2 also offer learners opportunities to justify their choices regarding the chosen boxes in relation to those that are not chosen. The learning outcome for figure 3 is drawing number 1 and the accompanying task is to draw number 1 using a drawing number pattern tool. I coded the task in figure 3 under CTP because it mediates learners' capabilities in writing or representing number 1 concept symbolically. The learning outcomes for the task in figure 4 are counting and writing number 1. I coded the task in figure 4 under AMC because it is about counting objects and writing their corresponding number which is 1 using free hand. This shows that the task provides learners with opportunities for further understanding of the number concept through making connections between quantities of objects, the number concept as well as writing its symbol.

I found that the tasks under units 1 and 4 would provide learners with mathematical opportunities to make their own judgments in terms of the meaning of a specific number concept and in representing quantity using numbers (Ronda & Adler, 2016). This is because the tasks are achievement based, activity based, hence they are learner centred. This implies that these example spaces and tasks can foster OBE to some extent because they are achievement oriented and activity based. I however found that the AMC tasks which mediate learners' capabilities in counting and writing are very few in both units 1 and 4. Although there is demonstration of how numbers from 0 to 9 can be written (for example task in figure 4), the textbook does not provide more opportunities for learners to practice writing the numbers. Furthermore, it is unlikely that the learners can manage to write the numbers without first attempting to trace these numbers on dotted number patterns. As such it would be better if learners were first given an example space where they could trace out the numbers. Provision of more dotted number patterns would also increase learners' capabilities in number concept by fostering learners' active interaction with the numbers through independent practice as demanded by the OBE curriculum (MIE, 2006).

The other limitation is that there are no tasks which provide learners with opportunities to represent number with objects to increase their mastery level of the number concept. For example, there are no tasks which require learners to draw a given quantity of objects to represent a number or to colour objects based on given number. This implies that there is lack of variety in terms of tasks provided to the learners through the textbook. Provision of little opportunities for writing numbers and representing them might limit learners' understanding of the number concept due to lack of practice, creativity and application.

## Conclusion

This paper has presented findings from textbook analysis study which aimed at examining mathematical opportunities available for grade 1 learners to understand number concept through OBE curriculum. The study has found that the textbook has provided learners with different levels of example spaces ranging from low to high level. However, the high level examples which would help learners to engage with various thinking patterns simultaneously are few. In terms of tasks, the study has found that the textbook has provided learners with opportunities to understand number concept mainly through counting objects but not through writing or representations. As a result, the textbook might not foster learners' active involvement and independent learning as required by the OBE curriculum goals. As these findings are only based on textbook analysis, there is need for further

studies to focus on how learners engage with this textbook in classroom to find out how these opportunities materialise.

# Two primary school teachers' pedagogical design capacity of using mathematics textbooks in Delhi, India

Meghna Nag Chowdhuri

University of Cambridge, Faculty of Education, Cambridge, UK; [nc.meghna@gmail.com](mailto:nc.meghna@gmail.com)

*India introduced a new National Curriculum framework in 2005, which included reformed goals for primary school mathematics in an attempt to make them more inclusive and student-centred. One of the efforts towards operationalizing the framework was to create new primary mathematics textbooks. In a context where textbooks are seen as the basis of all curricular activity – from sequencing, to teaching, to examination, it becomes important to understand how such reform-based textbooks are used by teachers. Drawing from a multiple case study in the context of government-run primary schools in Delhi, this paper reports that teachers seem to primarily reject these reform-based textbooks. Further it shows that while using the textbook, teachers have varied levels of design capacities to productively interpret the textbook tasks. The findings imply that curriculum and policy makers need to develop materials that teachers are firstly willing to engage with, and also provide space for teachers' design capacity to develop.*

*Keywords: Mathematics curriculum, primary teacher, pedagogic design capacity*

## Introduction

India, much like the rest of the world and especially the Global South, is attempting to improve teaching and learning practices in mathematics not just to increase learning outcomes, but also to ensure equity in its processes. In post-colonial India, quality and equity have remained fundamental to its Education system. These ideals are explicitly reflected in the National Curriculum Framework – 2005 (NCF 2005), which forefronts “processes” in mathematical activities as well as connecting mathematics to the lives of children (NCERT, 2005, p. 9). Another important feature of the Indian education system which is recurring in the literature is its ‘textbook culture’ (Kumar, 2005). The textbook continues to be the only resource in the classroom; and for state-run schools, prescribed and made available to students free. Kumar (2005) even claims that textbooks act as “de facto curriculum” (p. 67), despite an official curriculum framework and syllabus. Thus, it was not surprising that the textbook series (NCERT *Math-Magic*) was chosen as the first (and only) point of intervention to operationalize the visions of NCF 2005. Yet very little is known in India about how the textbook is navigated in classrooms. In this paper, which comes from a larger PhD study, I focus on the following research question:

*In what ways do teachers use reform-based textbooks in their mathematics classrooms?*

## Theoretical framework

Keeping the context in mind, as we explore the Anglophone literature in Mathematics education on the relationship between the teacher and the textbook (or other curricular resources), we see various developments. Different frameworks are used by researchers to make sense of these aspects based on how they conceptualise the teacher-textbook relationship as well as textbook as a resource. In this paper, I use Brown's (2003) framework of “design capacity for enactment” (p. 4), to explore how

teachers in the Indian context use textbooks. Central to Brown's idea is that teachers design textbook use by *offloading-adapting-improvising* based on the degree of responsibility they share with the textbook and their own resources. Thus, while using the textbooks, teachers may place agency primarily on the textbook (*offloading*), or change the activity based on their own needs (*adapting*), or change the course of the work altogether, making it very different from the textbooks (*improvising*) (Brown, 2003). While there is no prescribed hierarchy to their choice of offloading-adapting-modifying (one is not better than the other), these indicate the relevance and priority given to the textbook as a resource in teaching. Furthermore, this use is a function of both textbook *affordance* (textbooks' own attributes) and teachers' *pedagogical design capacity*. The notion of *pedagogical design capacity* – “teacher's capacity to perceive and mobilize existing resources in order to craft instructional episodes” (Brown, 2011, p. 29) – is evaluative in nature signifying teachers' capacity to use the textbook in productive ways. More recently Pepin, et al. (2017) have further described ‘teachers' design’ as a “deliberate/conscious act” of “creating something new” (p. 801); thus, bringing dimensions of intentionality and genesis to the fore. They further distinguish between ‘design’ (during planning); and ‘design-in-use’ (during enactment). This exploratory paper, only focuses on teachers' ‘design-in-use’, as they mobilise textbooks' affordances and create lessons (without considering teachers' intentions). By doing so, I examine limited yet crucial facets of the notion of teachers' pedagogical design capacity.

## Methodology

*Sample:* The larger study (a part of which is presented in this paper) is a multiple case study of ten teachers in four government-run municipality schools using *Math-Magic* textbooks. Delhi government schools, mandated to use these textbooks, were the site for the study. Importantly, these schools are low resourced both in terms of infrastructural resources, as well as teaching and learning resources. Getting permission to conduct my field work in these under-studied sites was particularly difficult. The ten primary school teachers were thus chosen based on convenience sampling, in schools which allowed me to conduct my study. However, I ensured that all the teachers had more than eight years of experience, including experience of using the textbook from the time of its introduction. Also, I focused on grades 4 and 5 teachers, where these textbooks were being used.

*Data collection:* Keeping the theoretical framing in mind, I focused on the three parts of the design capacity framework, and collected data on textbook affordances (the textbooks themselves), teachers' textbook use and thinking (through classroom observation and teacher interviews). While collecting *classroom observation data* (which is the data that I am analysing in this paper), I was given permission only to audio-record the classrooms, which was sufficient to capture the textbook use dimensions of teachers' teaching. The audio-recording was supplemented by observation notes, where I noted how the textbook was treated in the classroom (were the teachers reading it before starting the lesson, were they showing the textbook to students, did they provide time for students to read the text etc). In total, for each of ten teachers, I observed 3-4 lessons.

*Data analysis:* After transcribing and translating the audio recordings, the lessons were categorised into episodes which were defined on the basis of the tasks that teachers chose, so that an equivalent unit of analysis could be used to compare the textbook tasks with the teachers' chosen tasks. A total

of 34 lesson observations from the ten teachers, were categorised into 152 episodes (each episode corresponding to a task from the textbook analysis). These episodes were coded based on Brown's notion of offload-adapt-improvise. However, while doing so, two differences arose. First, teachers seemed to be using tasks of their own (or with the help of some other resource material) which were completely unrelated to tasks in the textbook. Thus, a notion of 'insertion' was necessary which accounted for such episodes, as done by Leshota and Adler (2018) in their adaptation of Brown's framework. Moreover, a second difficulty arose in defining the difference between adaptation and improvisation. One of the findings of the textbook analysis was that clearly stated goals for the tasks were missing, often leaving the tasks open to interpretation (perhaps even purposefully so) (e.g. Rampal & Subramanian, 2012). Thus, any modification to the tasks in the textbooks was coded as adapted use, without attempting to code episodes as being closer to the goals of the textbook task or not. As a result, a suitable adaptation to the 'offload-adaptation-improvisation' framework was made by identifying textbook task use in terms of 'direct use-adapted use-inserted use' which closely supported my data.

## Overall findings

*Teacher acceptance or rejection of the textbook:* Figure 1 below shows details of the textbook use of each of the ten teachers. There are two notable results from this analysis. Firstly, we can see that four teachers are using the textbook directly for majority of their teaching, and the remaining six teachers are using their own insertions for more than half of their episodes. This is a clear indication that the textbook is not being used most of the teachers in my sample, who are *rejecting* them.

*Direct use of textbook tasks:* While analysing the episodes of 'direct textbook use', there were two ways in which teachers used tasks. One was by following each sentence in the book, (often teachers would read the text, or ask students to read it out), thus addressing every aspect of the book as a script. The second way of using which seemed more flexible was to pick and choose tasks (or elements of them) as the teacher felt suitable. These two kinds of approaches to directly using the tasks were especially exemplified by teachers Jagdeesh and Kamala, discussed in the next section.

**Figure 1: Per cent of episodes observed categorised as direct, adapted or inserted textbook use**

## Contrasting cases of teacher design capacity

As discussed in my theoretical framework, the use patterns analysed above do not indicate the evaluative aspect of use; i.e teachers' pedagogical design capacities. Design capacities can be

explored within each of these three types of textbook engagements. For this paper, I look at two frequent direct users and their contrasting interpretations and mobilisations of the textbook affordances; i.e. their design-in-use. Jagdeesh and Kamala, both have eight years of teaching experience and both teach grade 4 in the same school. Jagdeesh tended to follow every task given in the textbook, while Kamala was pickier in terms of what she chose to include in her class. In the following section, I analyse how two focus tasks (Figure 2, 3) were used by Jagdeesh and Kamala; as they *designed* two very different lessons. While Jagdeesh used the textbooks' affordances in productive ways (as afforded by the textbook), Kamala does not do so.

### Focus tasks chosen for analysis and its affordances

The task in Figure 2 has two kinds of questions – 'Have you heard about marathon races?' invites students to engage with the context of the problem which follows. Such questions which were posed to students encouraging them to talk about their thinking, life experiences and feelings were coded as *expression tasks*. The following two questions are *specified tasks* (fill the blanks) where students are expected to answer the pre-formulated question. It is crucial to note that the text breaks down (possibly for support) the specified tasks into two stages, first asking students to find distance covered in 10 rounds (laps), and indicate its use to find the number of rounds for the 40 km.

Have you heard about marathon races in which people have to run about 40 kilometres? People run marathons on roads because the track of a stadium is only 400 metres.

10 rounds of a stadium track = \_\_\_\_\_ km

So, if you run a marathon on a stadium track, you will have to complete \_\_\_\_\_ rounds!

**Figure 2: Expression task and Specified task within Book 4 chapter 2**

In the second task shown below (Figure 3), we see another typical problem from the textbook which I refer to *generation tasks*. Here, the task is not pre-formulated, and to answer all these questions students have to bring in information from their own experiences or surrounding to answer the question. These particular aspects are viewed as task 'affordances', which are also aligned with the NCF reforms aiming to make mathematics process oriented and linked with everyday life.

\* How long does your school assembly take? \_\_\_\_\_

How long is your lunch break? \_\_\_\_\_

How long is your games period? \_\_\_\_\_

Is it the same as all the other periods? \_\_\_\_\_

**Figure 3: Generation task within Book 4 chapter 4**

### Comparison of teacher use of focus tasks:

Table 1 below, shows the different approaches taken by Jagdeesh and Kamala, while attempting these tasks. To provide some context, these teachers teach all the subjects for their class and are free to allot any time for each of the subjects, including for mathematics. Thus, the amount of time for each task or subject depends on the teachers' own goals for the lesson (there are institutional time limitations due to administrative work which are not discussed in this paper).

Teacher	Expression task	Specified task	Generation task
Jagdeesh (productive design)	<i>Expanded discussion</i>	<i>Explanatory approach</i>	<i>Opening the task</i>
Kamala (unproductive design)	<i>Omitted</i>	<i>Direct approach</i>	<i>Closing the task</i>

**Table 1: Comparison of teacher use of focus tasks**

*Omitting versus expanding the expression task:* Jagdeesh, instead of approaching the first *expression task* as a yes or no response, spends 10 minutes discussing different aspects of the context – what is a marathon, how a stadium looks like, what sports can be played in a stadium. He even encourages students to bring forth their own understandings, by listing the different sports they have heard being played in a stadium. He thus expands this expression task further creating his own probing questions supporting the task. On the other hand, Kamala omits this question all together, and only focuses on the specified tasks.

*Direct versus explanatory approach to specified task:* In his approach to the specified tasks, as possibly intended by the task, Jagdeesh uses the first question as the first step to the solution of the second question. That is, first finding distance travelled in 10 rounds and then discussing how many 10 rounds would be needed for 40 km. Throughout these stages he focuses on a detailed explanation of the solution procedure (spending 20 minutes), by breaking down the bigger question into smaller parts, which are more easily answered by the students. For example:

T: [We have to run] 40 kilometres. Now in 10 rounds, [we covered] 4000 meters that is 4 kilometres. In the next 10 rounds, how much will it be? In the next 10, if we add more, then how much is it adding 4 and 4? 8 km. After that another 10 rounds if we add?

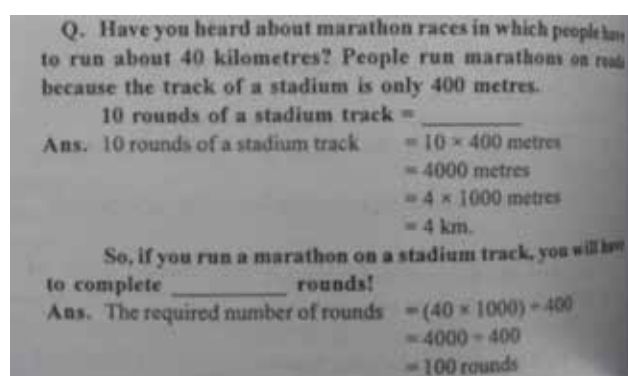

Thus, Jagdeesh focuses more on the process of the solution (with some support from the structure of the specified task) rather than presenting formal operations for solutions – such as multiplication.

Kamala on the other hand only spends 10 minutes in total on the task. She introduces the stadium with circumference 400 m at the beginning of the lesson and draws it on the blackboard to help model the stadium. Consequently, she only focuses on the first questions of the given task unlike Jagdeesh's use of the both the questions to explain the process of the solution. Instead of an elaborate explanation, we see Kamala giving direct procedures.

T: Now, this is given in your book. If you take 10 rounds of this stadium, then what will you get?  
 [] If you take one round of this stadium, then how much will it be? 400. You will multiply 400 with 10 rounds, then we will get how many metres we have run.

As we can see above, she directly tells the students that 400 needs to be ‘multiplied’ by 10 and consequently she writes the solution on the blackboard using the standard column algorithm form of multiplication. It is also important to note here, that Kamala was using an unofficial privately published guidebook while discussing this chapter alongside the textbook. The guidebook (see Figure 4) which acts like an answer book, provides a solution to each task in the textbook which just like her approach are also direct and formalised rather than process oriented (interestingly the guidebook even has a calculation error). Thus, instead of using the affordance within the textbook task (two questions as support for process explanation), Kamala takes a direct approach as given in the guidebook.

**Figure 4: Page C-10, Apollo guidebook**

*Opening versus closing the generation task:* While attempting the generation task (shown in Figure 3), we again see two very different approaches by Jagdeesh and Kamala. Jagdeesh while addressing this question (See Figure 3: How long does your assembly take?), tries to bring to fore the fact that the answer will vary based on the activity conducted during the assembly:

T: Hmm. Sometimes it is 15 minutes and sometimes it is 30 minutes. Sometimes, when there is a children’s meeting, it may take longer, otherwise the time for prayer meeting is about 20 minutes which includes the national song.

This shows that the Jagdeesh is open to the possibility that generation tasks can have many answers and the aim is to keep that in mind while answering. In contrast, Kamala gives definite answers which the students have to write down.

T: Who said it is 30 minutes? It is only 20 minutes. Write down 20 minutes.

As we can see above, in Kamala’s approach to the generation tasks, no openness is accommodated. Instead she renders the answer ‘30 minutes’ given by a student wrong and goes on to give a ‘correct’ answer to the student. Thus, despite the question being open (depending on the student’s perspective), she closes the kind of answers it can have.

If we look back at Table 1, along with the description of these episodes, we can see that while Jagdeesh seemed to interpret the key affordances within the tasks in alignment with the task’s rationale; Kamala’s interpretations contradict them. We can thus say that Jagdeesh seems to have a

higher pedagogical design capacity with respect to these textbooks; compared to Kamala. It is important to note that here I have not included evidence from teachers' own thinking which will enhance our understanding of the dimension of 'intentionality' motivating these designs-in-use. Furthermore, this does not imply that Jagdeesh and Kamala will always teach in these ways, and thus these are not fixed labels for teachers rather helpful indicators to help situate teachers' work in relation to the textbooks.

## Conclusion

In this paper, I have discussed primary school teachers' relationship with mathematics textbooks, in the context of Delhi, a city where there is hardly any research in understanding how teachers interact with textbooks. Especially the perspective of viewing teachers as designers (and not just 'implementers'), actively participating while using the textbooks, is completely missing from the Indian policy discourse. Although the need for reforming curriculum and textbook has been articulated strongly in the last 15 years, there is a need to now put teachers at the centre of the discussion. In such a context, using this approach to study Indian teachers is a novel idea (even though in other parts of the world this idea has been developed in innovative ways). By focusing on such a framework, with some adaptation in terms of categories and unit of analysis, this paper reports two findings.

Firstly, the finding that majority of the teachers in my sample are rejecting the textbooks, is a common finding across the globe when teachers encounter reforms. Yet this finding has severe consequences in a context where officially, this is the only textbook provided to teachers, and the schools are not resourced to provide supplementary materials. As we have seen, this might mean that teachers rely on unofficial privately published guidebooks which often have contradictory pedagogical suggestions. Or teachers might rely on their own traditional notions of teaching, thus reforms miss the opportunity of using the textbook's potential of becoming 'educative material' (Davis & Krajcik, 2005).

Secondly, within the group of teachers who were primarily accepting and directly using textbook tasks, by focusing on two teachers we were able to more closely investigate teachers' design capacities as they engaged with the textbook's affordances. In case of the two teachers we clearly see two different ways of perceiving and mobilizing the resource around the tasks; ie their pedagogical design capacity. Jagdeesh is attempting to approach the tasks more openly, attempting to engage students with the contexts integrated in the text and also giving more explanatory solutions. On the other hand, Kamala does not pick up the opportunity of engaging children with the context, and tends to give direct formulaic solutions and closes tasks which are more open. While Jagdeesh seemed to interpret the key affordance within the textbook productively, Kamala does not. Recognising that teachers' design capacities are not homogenous is important in terms of not just curriculum designing but also the accompanying teacher support. Small scale initiatives are starting in science education, such as Ramadas (2017) – where teachers' varied experiences with curriculum feeds back into curriculum design. Yet, these are almost absent in primary Mathematics. Developing partnerships of designing needs to be the next step for the Indian curricular context; which extends the view of teachers as designers and integrates that into curriculum designing (at national, state, school or

classroom level) (Jones & Pepin, 2017). After more than 10 years of introduction of reform-based textbooks such as *Math-magic*, conceptualising ways of developing design capacities needs to become central.

In this paper, I have explored different designs-in-use of the teachers, yet not discussed notions of intentionality: Are teachers consciously making these design choices? What are their intentions and goals behind them? By exploring designs-in-use across the three levels of textbook use: direct use-adapted use-inserted use, along with teachers' rationales for those choices, my larger study aims to develop this notion of 'pedagogical design capacity' further.

## Ability maps in the context of curriculum research

Lisbeth Liv Nøhr, Mia Onsvig Gregersen,

Andreas Lindenskov Tamborg, Jonas Dreyøe and Benjamin Brink Allsopp,

Aalborg University, Learning and Philosophy, Copenhagen, Denmark; ben@learning.aau.dk;

*Keywords: Curriculum development, rationalistic, dialogical, ability maps.*

### Background

As mathematics teachers and course planners, we have hands on experience, negotiating learning objectives with our colleagues and students. One important challenge we have noticed in this process has been overviewing and disambiguating potential learning objectives (Hansen, 2018). We have attempted to address this challenge by drawing what we call ability maps – network representations of potential learning goals. The ability maps have the purpose of structurally relating knowledge and skills within a certain field – a subset of this would then be the curriculum. The notation involves a simple syntax. Any potential learning objective, no matter how small, is considered an ability and is represented by a node. Whenever we agree that one ability includes another ability, we represent this with an arc pointing from the including ability to the included ability. There are additional rules about redundancy and layout to make these networks easier to explore.

Our experience from initial workshops is that these maps help co-located participants to identify and discuss potential learning goals. Furthermore, implemented digitally, the above is aided by interactive support, dynamic layout, and remote participation. More ambitiously it supports a process of online social evaluation of individual includes arcs to enable emerging consensus on what is considered important. We have developed a basic prototype and are currently considering a number of research and design questions involving ability maps. These workshops were held with mathematics teachers, but we think of ability maps as context independent both regarding subject and nationality. An additional challenge we have noticed in the process of negotiating learning objectives, and when introducing new users to ability maps, has to do with the proper (although often implicit) purposes of curriculum development. With this in mind, we ask: Which foundational perspectives in curriculum research explain the disagreement and how do ability maps fit into these perspectives? This question thereby investigates the different perspectives among researchers not practitioners.

### Method

Our approach is to orient ourselves in the literature to identify positions on curriculum research before considering how ability maps could be characterized by the perspectives. By reviewing the perspectives in the literature, we intend to discuss how and to what extent ability maps can address the challenges from the existing knowledge and discussions in curriculum research. In our search for literature we used the snowballing procedure. Snowballing is an approach in which a reference list, citations keywords in one or several papers are used to identify additional papers (Wohlin, 2014). The snowball methods often begin by identifying a tentative *start set* of papers. We began our search with the keywords: “Rationalistic”, “Tyler”, “Approach”, “Curriculum”, “Education”, which we searched for in Google and Google Scholar. We read 15 abstracts and 10 full papers. As the work presented in this poster is early stage research, we use the initial insights retrieved from the start set.

Within this process we found a framework for categorizing the role of curriculum, based on few authors which proved to be helpful in pinpointing the differences in the above literature and the potential role of ability map. The literature we read suggest two ways of approaching curriculum development referred to as a rationalistic and a dialogical approach. The rationalistic approach, represented by Tyler (1949), is described as technical and linear and focuses on structuring specific learning content. The dialogical approach is on the other hand dynamic and focuses on interactivity and flexibility (John, 2006). We adopt the distinction between these approaches as central.

### **Preliminary results from the review**

The two perspectives seem to explain much of the disagreement when negotiating learning objectives, however it was not so straightforward to place ability maps in either of these perspectives. At first glance, ability maps may seem to epitomize a rationalistic approach as it involves a high degree of structuring, detailed breakdown of objectives and has ambitions of technical implementations. However, the structure is not linear, but captures rich relations that are the result of negotiation and collaboration. Also, the structure does not dictate how teachers teach but only provides a map within which they can navigate. Furthermore, the identified abilities are not necessarily objectives. Deciding on which abilities to consider as objectives are an independent step from working with the maps and may not even happen until in the classroom. Finally, the ambition of technical implementation must not be interpreted as enforcing a mechanistic approach.

Ability maps thereby seem to transcend the dichotomy of a rationalistic approach and a dialogical approach. Although the division of rationalistic and dialogical approaches are beneficial in segregating views on curriculum, it is not helpful in categorizing ability maps. On the contrary, the dichotomy between these notions can represent a barrier in developing novel approaches to curriculum development. In this respect, ability maps seem to contribute with nuances that can support the practical aspects of curriculum development.

### **Further exploration**

To further explore and qualify these findings, a more comprehensive literature review is needed. This will contribute in nuancing and better understanding ongoing discussions in curriculum research and development and the potential contribution of ability maps. Further, ability maps are still at an early stage and experiments on its usage and usability is needed.

# Task design fostering construction of limit confirming examples as means of argumentation

Annalisa Cusi<sup>1</sup> and Shai Olsher<sup>2</sup>

*Tasks that require students to construct examples that meet certain constraints are known to be used in mathematics education. It is also well established that while examples are not proofs (for general statements), they have a supporting role in the preliminary stages of making sense of a certain mathematical phenomenon. In this study we examine a task design in which students are required to submit a supporting example to their explanation negating an existential statement. We introduce the idea of limit confirming examples and present their use in an analytical geometry task in a 10<sup>th</sup> grade class in Italy, along with the explanations they support in negating an existential statement. The results show that the design was effective in fostering the construction of limit confirming examples that could be considered as means of argumentation in the initial parts of proof construction.*

**Keywords:** Reasoning with examples, limit confirming examples, automatic online assessment,

## Theoretical Background

Alongside with computerized environments in mathematics education recent developments of online assessment platforms enable students to submit open ended tasks that are automatically assessed (Olsher, Yerushalmy, & Chazan, 2016). One challenge in designing tasks for these environments is to design means of mathematical argumentation that could be automatically analyzed (Yerushalmy, Nagari-Haddif, & Olsher, 2017).

One form of open ended that elicits different characteristics in student answers, and serves means of argumentation about them is by providing examples (Buchbinder & Zaslavsky, 2009). Examples could serve as inductive of general example-based arguments (Dreyfus, Nardi, & Leikin, 2012), thus providing an initial step in the proving process. Although there are limitations to the use of empirical examples as proof (Zaslavsky, 2018), research recognizes merit in arguing why characteristics of a certain example would work for any other one as well (ibid).

Students use at times systematic exploration of examples as a proving strategy, referring to their examples as cases, and then *prove by cases* (Buchbinder, 2018). When constructing cases, the literature recognizes several strategies that could lead to constructing refutations. One of these strategies, generating *limit cases*, might be constructed by creating an auxiliary problem in which the condition of the initial problem is transitioned to the limit (Balk, 1971), and is also referred to as *extreme cases* (Clement, 1991) or *boundary cases* (Ellis, Lockwood, Williams, Dogan, & Knuth, 2013).

In this paper, we present a task design aimed at fostering students' construction of a specific type of examples - *limit confirming examples*. We introduce this term as a theoretical result of our a-priori analysis of the task (for this reason, we will define and exemplify this concept after presenting the task). Our hypothesis is that limit confirming examples represent possible effective means of

argumentation (Stylianides, Beida, & Morselli, 2016) towards persuasion that certain characteristics could not co-exist in a specific mathematical context. This study is part of a wider collaboration for studying the design and use of online formative assessment activities using the STEP platform<sup>1</sup> (Olsher, et al., 2016).

## Methodology

We adopted a design-based research approach (Cobb, et al., 2003), characterized by cycles of design, enactment, analysis and redesign. The pilot study on which this paper is focused has been developed within the first cycle of design. In particular, here we present aspects of both the design phase and the analysis phase.

The participants were 25 secondary Italian students, from a 10<sup>th</sup> grade class (students aged 15-16) of a scientific lyceum, in Italy. We focus on the students' resolution of a task that is part of an online activity within the context of analytical geometry, specifically lines intersecting a segment. The online activity was proposed to the group of students at the end of the school year, when they had already studied some basis of analytic geometry (in particular, coordinates of point, equations of lines, conditions of perpendicularity and parallelism).

The activity comprised three tasks designed as interactive diagrams describing a geometrical context on a Cartesian axis, using the STEP platform. The interactive diagrams were constructed using GeoGebra, and enabled the participants to construct or drag a set of elements in the diagram, according to the predefined characteristics determined by the designers of the task. The context was described in the task. The participants needed to submit examples satisfying different conditions. Students had to complete the whole activity within one hour.

## The task

The task requires the students to consider the segment connecting the points A(2,4) and B(-3,2) and the family of lines  $y=mx$  (see figure 1), and addresses the following existential statement: “*There are two lines of the family perpendicular to each other and both intersecting the segment AB*”. The students are asked to state if the statement is true or false, then, in case they think it is true, to submit the equations of two lines that satisfy it, or, in case they think it is false, to explain why and submit a screenshot that supports their choice.

**Figure 1: Applet accompanying task requiring an explanation and a supporting example**

<sup>1</sup> Seeing the Entire Picture - STEP – is a formative assessment platform developed at the University of Haifa's Center for Mathematics Education Research and Innovation (MERI). For more detail about this platform, see [www.visustep.com](http://www.visustep.com).

The existential statement could be formulated as follows: “There are two lines that satisfy all of the following three properties: (A) the two lines belong to the family  $y=mx$ ; (B) the two lines are perpendicular to each other; (C) the two lines intersect the segment  $AB$ ”. Therefore, it could be thought as  $A \wedge B \wedge C$ , that is an intersection of three conditions. Proving that this statement is false requires to prove that the universal statement  $\neg(A \wedge B \wedge C)$  is true, which is logically equivalent to each of the following statements:  $(A \wedge B) \rightarrow \neg C$ ;  $(B \wedge C) \rightarrow \neg A$ ;  $(A \wedge C) \rightarrow \neg B$

So, in order to prove that the existential statement “There are two lines of the family perpendicular to each other and both intersecting the segment  $AB$ ” is false, it is enough to prove one of the following universal statements:

- 1) “If two lines belong to the family  $y=mx$  and are perpendicular to each other, then they do not both intersect the segment  $AB$ ”  $((A \wedge B) \rightarrow \neg C)$
- 2) “If two lines belong to the family  $y=mx$  and both intersect the segment  $AB$ , then they are not perpendicular to each other”  $((A \wedge C) \rightarrow \neg B)$
- 3) “If two lines both intersect the segment  $AB$  and are perpendicular to each other, then they do not both belong to the family  $y=mx$ ”  $((B \wedge C) \rightarrow \neg A)$

Students should be aware of the fact that identifying a *confirming example* for each of the universal statements 1, 2, and 3 is not enough to prove them. Yet, students’ choice of the examples that should support their claim that an existential statement is false could represent an important sign to highlight their awareness about what kind of examples could be the starting point for the construction of argumentations.

### Limit confirming examples

We define *limit confirming examples* (for a universal statement) as specific limit, or boundary examples that incorporate within them all other possible confirming examples. The characteristic of incorporating all possible confirming examples makes limit confirming examples effective supports for construction of complete argumentation about the truthfulness of a universal statement because they foster the activation of a “domino effect”, enabling students to highlight why all the other possible examples that can be constructed will confirm the statement (in the following, we refer to the confirming examples that are not limit confirming examples as *not-limit confirming examples*).

Figure 2: Limit confirming examples (a, b) and a not-limit confirming example (c) for statement 1

We refer to the task introduced in the previous paragraph to exemplify this idea. There are two limit confirming examples (Figure 2, a and b) for statement 1 (“If two lines belong to the family  $y=mx$  and are perpendicular to each other, then they do not both intersect the segment  $AB$ ”).

These two examples are characterized by the fact that one of the two lines intersects the segment at one of its edges. They are *limit confirming examples* because, if we consider other examples constructed in the same way (two lines passing through the origin and perpendicular to each other), if one line intersects the segment in a point that is not an extreme for  $AB$ , the other line certainly does not intersect  $AB$ , as highlighted in Figure 2 (c), a screenshot submitted by a student.

As regards statement 2 (“If two lines belong to the family  $y=mx$  and both intersect the segment  $AB$ , then they are not perpendicular to each other”), there is one *limit confirming example* (Figure 3a) characterized by the fact that the two lines considered are those that intersect the segment in its extreme points. We can consider it a *limit confirming example* because all the other couples of lines intersecting the segment and belonging to the family (Figure 3b) form an angle that is smaller than the one highlighted in figure 3a, meaning that the two lines are not perpendicular.

**Figure 3: Limit and non-limit confirming example for statement 2**

The limit confirming example (Figure 4a) for statement 3 (“If two lines both intersect the segment  $AB$  and are perpendicular to each other, then they do not both belong to the family  $y=mx$ ”) is characterized by the fact that the two lines considered are perpendicular to each other, intersect the segment  $AB$  in its edges and intersect each other in the point that is at a minimal distance from the origin (that is the point of intersection between the circumference whose diameter is  $AB$  and the line passing through the origin and the center of this circumference). This is a *limit confirming example* because all the other possible couples of lines perpendicular to each other and intersecting the segment  $AB$  intersect each other in a point of the circumference that is at a greater distance from the origin (Figure 4b) or in a point inside the circumference whose diameter is  $AB$  (Figure 4c), so they do not belong to the family  $y=mx$ .

**Figure 4: The limit confirming example for statement 3 (a) and two not-limit confirming example incorporated within it (b, c)**

## Methodology of analysis

Some important elements of the context must be added before presenting the methodology of analysis and the results. First of all, we did not share with students the logical analysis of the statement, that is the identification of  $A$ ,  $B$ ,  $C$  and the reflection on the logical equivalence of  $\neg(A \wedge B \wedge C)$  and each of the statements  $(A \wedge B) \rightarrow \neg C$ ;  $(B \wedge C) \rightarrow \neg A$ ;  $(A \wedge C) \rightarrow \neg B$ . Moreover, we did not explain what limit-confirming examples are, neither we asked them to find out examples with specific characteristics.

The aim of our analysis was, on one side, to highlight if the design of the task was effective in fostering students' construction of limit-confirming examples and, on the other side, to detect, in students' answers, elements that could contribute to the construction of complete argumentations. Our units of analysis were the answers given by students to the task, including three main aspects: (1) students' claims about the truthfulness of the statement (level 1); (2) students' choices of the examples to be sent to support their claims (level 2); (3) students' verbal arguments to justify their claims (level 3)..

As regards the second level of analysis, we: (a) initially distinguished between the answers characterized by the submission of a limit confirming example and the answers characterized by the submission of a not-limit confirming example; and (b) subsequently distinguished, among the limit confirming examples sent by students, between the categories of limit confirming examples presented in the previous paragraph (that is those referred to statement 1, or 2, or 3).

The analysis of the verbal arguments sent by students to support their claims (level 3) was developed at a qualitative level, focusing on: (a) the reference to the chosen example and the coherence/incoherence between the choice of the example and the content of the verbal argument; (b) hints of students' awareness about the role that the examples they chose could play to support the construction of a complete argumentation to justify their claim.

## Results

As regards level 1 of analysis, all students correctly stated that the statement is false.

Focusing on the examples they sent (level 2 of analysis), most of them (22 out of 25) submitted a limit confirming example. Among the 3 remaining students, two submitted a not-limit confirming example, while the third one did not submit any example. Further analysis of students' choice of limit confirming examples shows that most of them (17) submitted the limit confirming example related to statement 2 (Figure 3a); 3 students submitted a limit confirming example related to statement 1 (Figure 2); one student sent the limit confirming example referred to statement 3 (Figure 4a); one student sent a limit confirming example related to statement 1, containing also the sketch of the circumference whose diameter is  $AB$ .

In the following, we present some results of the analysis of students' verbal arguments (level 3).

Among the 17 students submitting a limit confirming example related to statement 2 (Figure 3a), 7 show some form of consideration to the fact that their example incorporates all other possible examples. Some of the students explicitly refer to the other possible examples incorporated into the limit confirming example, as shown in Figure 5.

**Figure 5: The screenshot submitted by S8 and the corresponding argumentation**

Other answers show an implicit reference to the set of examples that can be generated starting from the submitted limit confirming example. For example, the argument proposed by S9 (Figure 6) refers to the idea of “widest angle”, making an implicit reference to the set of possible couples of lines passing through the origin and intersecting AB.

**Figure 6: The screenshot submitted by S9 and the corresponding explanation**

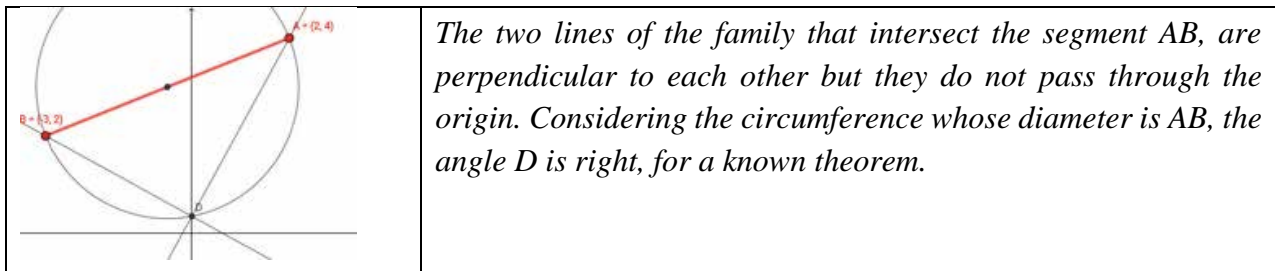

The other 10 students that submitted a limit confirming example related to statement 2 either did not submit an explanation (1 student), or submitted explanations with no evidence about of the role of a limit confirming example. These incomplete argumentations included either a repeated statement about the claim not being true, or an additional verbal description of the submitted example, or referred to aspects not directly linked to the provided example.

The choice of the limit confirming example to be submitted seems to influence the construction of the related argumentation. In fact, none of the three students who sent a limit confirming example referred to statement 1 (figure 2) show some form of consideration to the fact that their example incorporates all other possible examples: One of them do not submit an explanation. The second student reformulated the claim about the initial statement not being true, and the third student (S16, Figure 7) referred to the relation between the slopes of two perpendicular lines, without focusing on the possibility of creating other examples starting from the limit confirming one.

**Figure 7: The screenshot submitted by S16 and the corresponding explanation**

The single explanation submitted along with a limit confirming example referred to statement 3 (S18, Figure 8) does not highlight a consideration to the fact that their example incorporates all other possible examples.

**Figure 8: The screenshot submitted by S18 and the corresponding explanation**

## Conclusions

The most unambiguous outcome of this limited study is that 22 out of 25 students (88 percent) submitted limit confirming examples to support an explanation that disproves an existential statement in the form  $A \wedge B \wedge C$ . Disproving this statement is equivalent to proving one of the universal statements  $(A \wedge B) \rightarrow \neg C$ ;  $(B \wedge C) \rightarrow \neg A$ ;  $(A \wedge C) \rightarrow \neg B$ . The students provided the limit confirming examples without being previously introduced to these ideas, mostly since students should be aware that a confirming example is not enough for a proof (Buchbinder & Zaslavsky, 2009; Zaslavsky, 2018), in the same way in which a non-confirming example for the existential statement is not enough to disprove it. Yet, identifying limit confirming examples for one of the statements  $(A \wedge B) \rightarrow \neg C$ ;  $(B \wedge C) \rightarrow \neg A$ ;  $(A \wedge C) \rightarrow \neg B$  was something that most students could come up with on their own as a supporting example. This result supports the notion that these examples might be an easier starting point in the argumentation process, opening the way to the construction of a complete argumentation somewhat aligned with example-based arguments (Dreyfus, Nardi, & Leikin, 2012) as means of argumentation (Stylianides, Beida, & Morselli, 2016) in an initial stage of the proving process.

Since many students that submitted a limit confirming example were not able to construct rich argumentations, our study also shows that, although choosing to submit a limit confirming example could be promising in fostering students' construction of complete argumentations, it is not sufficient. While the topic of the tasks in this study is analytical geometry, and used 3 properties, we believe that additional mathematical strands could be explored, while not necessarily limiting the number of properties to 3, but our final conclusions in terms of task design are driven straight from the finding of this study and the tasks studied: We suggest the following criteria for the creation of effective tasks aimed at developing learners' abilities in creating and using limit confirming examples: (a) analysis of complex false existential statements involving at least 3 properties to be satisfied by the elements of a precise domain; (b) possible deconstruction of the statement to corresponding universal statements to be proven; (c) requirement of argumentation and a supporting example about the truthfulness of one of these universal statements.

## Limitations and future steps of the research

This research included a single task and a small sample of students. In order to further investigate and reaffirm the findings more tasks should be developed using this design, and tested in different settings. Furthermore, the use of the STEP environment could support the teacher in automatically having the student submissions categorized, thus providing grounds for research about teacher use.

# **Towards improving teaching and learning of algorithmics by means of resources design: a case of primary school education in France**

Rafalska Maryna

rafalska.maryna@gmail.com

*This article is devoted to the problem of design of resources in algorithmics for teachers of primary school in France. We investigate what elements should contain such resource in order to support the learning intended by authors of the resource, during its implementation by teachers who works in different contexts. To contribute to this question, we study the design principles of a particular resource in algorithmics. We follow this resource from the moment of its creation by a researcher and an experienced teacher to its appropriation and usage by three ordinary teachers. Paper describes how the results of analysis of lessons observations, interviews and collective discussions with teachers pointed to missing elements of the resource and, hence, contributed in its enhancement. The results of the study aim to bring some elements for improving the teaching of algorithmics by means of resources and, as a result, to support the learning of the involved concepts.*

*Keywords: Algorithms, resources, primary education, teacher.*

## **Introduction**

Algorithmics (Lagrange, 2014) is more and more present in school education of different countries. In France, the elements of algorithmics and programming were introduced in primary and middle school curricula in 2016. In our previous work, we analysed the didactical transposition (Chevallard, 1985) of the main concepts of algorithmics in French curriculum of cycle 4 (grades 7-9) and showed its partial nature with a focus on the effectiveness aspect of algorithm and on the usage of algorithm as a tool (Modeste & Rafalska, 2017). The following analysis of didactical transposition of concepts of algorithmics in French curriculum resources for cycle 3 (grades 4-6) showed the existence of the same orientations.

In French curriculum of cycle 3, content related to algorithmics and programming is included in the chapters “Mathematics” and “Sciences and technologies”. For example, in the theme “Space and geometry”, it is suggested to make an introduction to programming by using activities of spotting and displacement (coding the movement of a robot or a character on the screen) as well as geometrical activities (construction of simple figures and figures composed of simple figures). In the theme “Materials and technical objects”, it is mentioned that the notion “algorithm” could be discovered by pupils using “visual applications”. Curriculum guidelines for teachers (published by Ministry of education of France) highlight the importance of development of pupils’ knowledge of “the basic principles of algorithmics and software design” and indicate that the usage of unplugged activities could be the first step for introducing pupils to the notion of algorithm. However, the concept of algorithm is not defined and it seems that the main learning objectives of such activities is the development of rigor. Most of given examples present algorithm through programming tasks, using robots or different environments (like Scratch, Scratch JR, Géotortue, etc.). Analysed textbooks for cycle 3 (in particular, collections Nathan and iParcours for grade 5, Delta for grade 6) follow the recommendations of the curriculum and teacher’s guides, and propose mostly programming tasks

(usually about drawing figures on the screen) and games in Scratch without distinguishing the notions of algorithm and program. Such focus on programming leaves out other important aspects of algorithm, for example, the role of algorithms for problem solving.

Interviews with teachers of primary school revealed that many of them have never been trained either in algorithmics or in programming, and don't understand completely the goals and relation of the new topic to other parts of the curriculum. To prepare their lessons, they tend to use curriculum texts, teachers' guides, textbooks and existing online resources (that also propose mostly tasks of programming in Scratch). In spite of changes in French curriculum made in 2016, there are still many teachers of primary school who have not yet made lessons in this topic. This leads to the situations when in the same class of grade 6 (the first year of middle school) there are pupils with different levels of knowledge in algorithmics and programming.

We make the hypothesis that one of the ways to overcome the institutional constraints, to improve the teaching and, in consequence, learning of algorithmics, is the development of resources for teachers that takes into account different aspects of the notion of algorithm. However, the existed studies, like Aldon et al. (2017), showed that a teacher in interactions with a resource can interpret it in different ways. Sometimes, the didactical situation designed by a teacher on the base of a resource has different intentions comparing to the intentions of the authors of the resource. Thus, the elaboration of resources in algorithmics requires the design of tasks as well as the development of resources design principles that could "assure" their distribution and following usage with the relevance to initial learning goals. The research question that we investigate in this article is the following:

What elements should contain a resource in algorithmics in order to support the learning intended by the authors of the resource, during its implementation by teachers who works in different contexts?

To contribute to this question, we investigate the design principles of a particular resource in algorithmics. In the next sections, we present the theoretical framework, the methodology choices and the project framework in which our study is anchored. Then, we propose some elements of data analysis and the corresponding results. In the last section, we answer the research question and draw our conclusions.

## **Theoretical framework**

This study refers to the documentational approach to didactics (Trouche et al., 2018), which proposes a holistic approach to teachers' work, taking into account the new universe of resources to teacher use, design and re-design. The central role in this approach is given to the notion of resource that is used in the sense of a tool that "re-source" the teacher's work (Adler, 2000). In addition to the material resources (like textbooks, curriculum materials, etc.), this approach also takes into consideration such resources as discussions with colleagues and researchers, students' answers, etc. Teacher integrate resources in their system of resources and design on their base his/her documents related to a certain class of situations. In Pepin, Gueudet, & Trouche (2017), the notion of document is presented as a combination of the resources adapted and re-combined, the ways the teacher uses them (which include the stable organisations of associated activities and particular usages), and contain the 'knowledge' guiding the usages.

The documental approach to didactics provides the tools for following the evolution of a resource during its adaptation and usage by a teacher. As in this study we are also interested in the results of resource implementation in class, we refer to the theoretical framework of the structuring of the milieu as well (Brousseau (1998); Margolinas (1995, 2002); Bloch & Gibel (2011)). It allows to analyze both a teacher's and pupils' positions in a didactical situation. Thus, taking the pupils' point of view leads to bottom-up or ascending analysis starting from the moment when a generic pupil is confronted with a material environment (milieu), i.e. without *a priori* didactical intentions, to the institutionalization of knowledge, including the phases of experience or action during which the knowledge at stake is encountered. Top-down or descending analysis corresponds to the teacher's point of view. It starts from the confrontation of a teacher with a construction milieu in an unfinalized situation, includes the phases of development of teacher's global project (concerning a theme of study that involves one or several lessons) and local project (concerning a particular lesson), and ends with the devolution and observation of pupils' activities in a didactical situation.

In our paper, we also use the notion of didactical bifurcation proposed by Margolinas (2005) for modelling the case when pupils confronted with a material milieu, invest themselves in a situation that is different from the one intended by a teacher. Margolinas distinguishes two types of marginal branches of a situation: a-didactical marginal branch (when pupils acquire new knowledge that is not in the teacher's project) and nildidactical marginal branch (when pupils don't acquire new knowledge). In analogy with the notion of didactical bifurcation, Aldon et al. (2017) proposed the notion of bifurcation of construction: when the construction situation (in which a teacher confronts with a resource and interprets its intentions for constructing his/her own project) carries the intentions distinct from those of the resource and, in consequence, it leads to a didactical situation different from the didactical situations potentially carried by the resource.

## Methodology

Our study is anchored in the French PREMaTT project<sup>1</sup>. The objective of the project is to stimulate the collaborative design of resources for teaching, in a network of schools, supported by researchers and a monthly meeting in a "laboratory for innovative design" (Trouche, 2019). In particular, in frame of the project the teachers and researchers worked on the design of tasks and resources for teaching of algorithmics aiming to make them useful for other teachers. Collaboration between researchers and practitioners is widely used in design-based research for bringing solutions to problems of practice (in particular, by producing new artefacts) and for contributing in the research by identification of design principles.

Our methodology is based on the confrontation of *a priori* analysis (built around the intentions of authors of the resource's, analysis of the resource and situations carried by it) with a posteriori analysis (built on the observation and analysis of implemented situations by ordinary teachers) as well as on the analysis of revealed dysfunctions, if any.

---

<sup>1</sup> PREMaTT: thinking the resources of mathematics teachers in a time of transitions (<http://ife.ens-lyon.fr/ife/recherche/groupe-de-travail/prematt>)

For our study, we constituted two teams. The first one involved a researcher and an experienced teacher who had been working part-time at a research laboratory and part-time in a primary school in the city centre for many years. The team worked on the design of didactical situations aimed to familiarize pupils with different properties of the notion «algorithm» and to show the role of algorithms in problem solving. The effectiveness of the developed tasks for supporting the intended learning was validated in result of confrontation of a priori analysis with a posteriori analysis of situations implemented in a class of grade 5 (10 years old pupils) by the experienced teacher.

The scenario of lessons developed by the team was chosen as the first version of the resource to transmit to the ordinary teachers. This choice was based on the hypothesis that this scenario, which takes into account both learning constraints and constraints of teacher practice, would constitute a sufficient support for teachers in order to design their own lessons project that will foster the intended learning. It included the description of the developed tasks (in particular, necessary material support, problems for pupils to solve, guidelines for teachers concerning implementation of the situations in class) and information about managing the lessons (timing, forms of class organization of pupils, etc.).

The second team involved three teachers (Natalie, Victor, Ida) who had been working together at a primary school in a socially disadvantaged part of the city for more than 5 years. The teachers obtained their initial education in different subjects<sup>2</sup>: Natalie in biology, Victor in literature and Ida in informatics. All of them at the time of the study taught in class of grade 5. Except Ida, who worked at the beginning of her career as a database operator for 10 years, the teachers have never been trained either in algorithmics or in programming. Natalie made a few lessons in programming in Scratch, while the others have never taught this topic. The teachers' mission was to prepare lessons using the scenario and to make them in their classes as well as to give the reflexive feedbacks during interviews and collective meetings with the first team. Ida, Natalie and Victor were also asked to elaborate a scenario that could be a possible continuation of the proposed one. The members of the first team didn't intervene in the work of the teachers (except a short presentation of the elaborated tasks by the researcher).

### **Collected data and their exploitation**

For our study we collected the following data: answers of teachers to the questionnaire about their education, professional path, teaching experience, system of resources in mathematics and participation in collective work; video of collective work of Ida, Natalie and Victor before the implementation of the scenario in their classes; videos of the lessons of three teachers; pupils' written production; interviews with Ida, Natalie, Victor after the lessons; scenario proposed by three teachers as a possible continuation of the first one; videos of two collective meetings of the members of both teams (the first one, concerning the results of the implementation of the scenario in three classes; the second one – a collective discussion about a possible continuation of the first scenario).

---

<sup>2</sup> In France, in order to enter a teacher training program, candidates must have at least a Bachelor degree in any speciality.

We used the lessons videos to make the *a posteriori* ascending analysis of didactical situations implemented by each teacher and confronted it with the *a priori* analysis. We were particularly interested in the episodes that show existence of pupils' activities that were not expected. In such cases we questioned the reasons of appearance of didactical bifurcations and identified the type of marginal branches (regarding the didactical project of the authors of the scenario). We used the video of class observations to analyse teachers' actions in the class (particularly, the devolution of the situations made by the teachers) and their possible influence on the appearance of alternative pupils' projections of a didactical situation based on the material milieu. In the video of collective discussions of the teachers before and after experimentations as well as in the interviews with them, we were looking for episodes that could bring to light the logic of their actions in class and their choices made during the construction of the situations on the base of the scenario. To understand teachers' considerations about the role and possible place of constructed didactical situations in their global project of teaching algorithmics and programming, we analysed the scenario developed by Ida, Natalie and Victor as a possible continuation of the first one as well as the video of its collective discussion. The revealed dysfunctions in construction of didactical situations (bifurcations of constructions) as well as in their implementation in class allowed to revise the design choices made *a priori* and to identify what elements were missing in the resource.

### **Analysis of lessons observations**

Due to space restrictions, we present in this section the elements of the analysis of Ida's, Natalie's and Victor's lessons and show how it contributed to the identification of missing elements of the resource. We start from a short description of the first two situations proposed in the scenario. Then, we show how Natalie, Ida and Victor made the devolution of the second situation in their classes and the corresponding pupils' activities.

The proposed scenario included the sequence of situations with a didactical dimension (Bloch, 2000) during the work on which pupils "re-invent" sorting algorithms. Implementation of the situations doesn't require a computer and propose the following material support: playing cards and grid with defined places for putting cards on it in an aligned list.

In the first situation of the sequence, pupils choose randomly 7 cards from 13 cards of one colour and put them face down on the grid. The goal is to sort the cards by returning only two cards at a time. The situation is used to introduce the material milieu (cards, grid and three allowed operations: "to take two cards", "to put them in the right order", "to place them on an empty place of the grid") and prepare pupils for the following tasks. The target knowledge includes the understanding that at a time one can put two cards in "local" but not necessarily in "global" (between all cards) order, as well as the comprehension of the possibility to sort the cards in a finite number of permutations using the defined operations. The results of experimentations in the class of the teacher from the first team showed that most of pupils' procedures in this situation are based on the usage of the memory.

In the second situation, one pupil should sort the cards of another one by giving him instructions with respect to the allowed operations. The pupil, who has cards, doesn't show their values to the pupil who gives instructions. All cards could be turned over only after the "pupil-speaker" says "stop". The objective of the task (that imitate, in some sense, the relation between a human and a machine) is to

foster the development by pupils of sorting strategies that will be generalised in the following situations.

Natalie made devolution of the second situation, emphasizing on the phrases that pupils can use for giving instructions to their classmates: “take card number ... and number ...”, “put them in the right order”, “place them on the grid”, “stop”. She highlighted that the use of other sentences is not allowed. The observation of pupils’ activities in this class showed that all pupils invested themselves in the main branch (regarding the didactical project of the authors of the scenario) and were working on the development of sorting strategies.

Ida and Victor, while explaining the challenge of the second situation, mentioned only that pupils “will do the same thing like in the first task, but this time, there is one pupil who gives instructions and another one who executes them”. They didn’t discuss with pupils the phrases that they are allowed to use for giving instructions, emphasising only on the necessity that “the ‘executor’ have to do exactly what the speaker says” and “that it is very important to be precise in the language”. Victor gave in his class the following criterion of success in the task: “if the cards are in the right order, it means that ‘the speaker’ was very good”. Such devolution of the situation led to its different interpretations by pupils and evoked pupils’ activities which were not intended by the authors of the scenario. For example, part of pupils in the class of Ida, for whom it was not evident which phrases to use, invested themselves in the nildidactic branch. They used the commands “exchange the cards” or “put back without exchanging”, factually trying to guess if the cards, they claimed to take, are in the right order or not. In the class of Victor, we observed one pupil who was searching for the optimal formulation of the sentence for sorting the cards of his classmate. He proposed the following solution: “you take two cards that you want, sort them and put them on the grid, and you continue like this until all cards will not be in the right order”. This answer was not accepted by Victor which produced a protest from the pupil who was sure of the correctness of his answer.

Thus, in the classes of Ida and Victor we identified the marginal branches that were not expected by *a priori* analysis. It happened due to the way chosen by the teachers for the devolution of the situation. The following analysis of collected data showed the differences between Ida’s and Victor’s interpretations of the objectives of the first two situations with those intended by the authors of the scenario. For example, Victor, expecting that pupils would find the sorting strategies during the work on the first situation, saw the goal of the second one in the development of pupils’ competencies to verbalise the solving procedures. This explains his choice of devolution for the second situation, when he left open the possibility of different formulations of pupils’ strategies.

The obtained results of the analysis contributed to improve the resource. More specifically, the identified bifurcations of construction showed the necessity to describe the expected pupils’ procedures in the first situation and the target knowledge in the second one as well as to provide the help for the devolution of the second situation (to insist on the “authorised” sentences for giving instructions with a link to the property of feasibility of algorithm).

## Discussion and conclusion

Our study puts the light on certain difficulties that teachers of primary school could have in interactions with resources in algorithmics (and, more generally, with resources that involves the

concepts in which teachers don't have enough knowledge) and their influence on pupils' learning. In the case of Victor, flaws in a priori analysis of the proposed situations (in particular, wrong anticipation of possible pupils' procedure and identification of target knowledge) led to the construction of a didactical situation distinct from the one supposed by the authors of the resource. In consequence, the evoked learning activities of pupils didn't comply with intended ones.

It seems, that more pertinent choice of devolution of the second situation made by Natalie could be explained by the fact that she had taught a few lessons in Scratch before the experimentations took place and, as she said, "the usage of the given phrases for sorting cards is similar to the usage of blocs in Scratch for constructing a program". However, we also identified a few dysfunctions in her class that could influent on the learning outcomes. For example, Natalie didn't recognise in the pupils' answers the "germs" of the sorting algorithm with which she was not familiarized before. Hence, she didn't take them into account in the validation phase. Another example, which is common for the lessons of three teachers, is the lack of decontextualization in the phases of conclusion.

From the interview with Ida, Natalie and Victor as well as the analysis of the scenario proposed by them as a possible continuation of the first one, we draw the conclusion that they don't see all didactical potentiality of the resource proposed by the first team, focusing mostly on the effectiveness aspect of algorithm (Modeste, S., 2012). Moreover, analysis of the collective discussion about the possible prolongation of the first scenario showed that the situations, even didactically pertinent, could be discarded by the teachers if they don't see the connection between the target knowledge and curriculum requirements.

Revealed dysfunctions pointed to key elements to transmit to teachers by means of a resource in algorithmics in order to support the intended learning: *a priori* didactical analysis of situations proposed by a resource; target knowledge and ways of its gradual decontextualization in class; principal results of experimentations carried out in class (e.g. the examples of pupils' procedures, frequent errors, etc.); information regarding the basic theoretical and epistemological aspects of concepts involved in a resource; possible place of a resource in learning progression with link to curriculum requirements. Due to the fact that the transmission of the mentioned elements by means of a particular resource could make it too long and, in a result, not usable by teachers, the question of the structure of a resource in algorithmics need to be addressed.

Results presented in this paper, concerned only the first cycle of experimentation with the resource. The next step is to refine the design principles of a resource in algorithmics via the following cycles of experimentations with the revised resource as well as with other resources. Future work is also likely to investigate the impact of the resources designed on the base of the results of the study, on teaching and learning algorithmics at primary school.

# Length measurement in the textbooks of German and Taiwanese primary students

Silke Ruwisch<sup>1</sup> and Hsin-Mei E. Huang<sup>2</sup>

<sup>1</sup>Leuphana University Lueneburg, Germany, [ruwisch@uni.leuphana.de](mailto:ruwisch@uni.leuphana.de)

<sup>2</sup> University of Taipei, Taiwan R.O.C., [hhuang22@utapei.edu.tw](mailto:hhuang22@utapei.edu.tw)

*Length measurement plays a prominent role in most countries. The purpose of this study was to examine similarities and differences in Taiwanese and German elementary written textbooks concerning the treatment of length understanding, measurement, and estimation. Our analysis showed that procedural affordances dominate the conceptual learning situations in both countries, even more in Germany than in Taiwan. Although ‘units can be converted’, ‘reasoning and justification’ and ‘benchmark learning’ were the most common conceptual elements in both countries, their importance differed. The comparison of procedural elements showed that both countries mainly focused on ‘unit conversion’, ‘measuring with a ruler’, and ‘addition and subtraction of length’. The Taiwanese textbooks concentrated more on concrete actions, whereas the German textbooks focused on more abstract and mental procedures.*

*Keywords: length measurement, textbook analysis, binational comparison, primary school*

## Introduction

Length measurement plays a prominent role in measurement education in most countries (Buys & de Moor, 2008, Clements & Bright, 2003). Nevertheless, researchers all over the world continuously report poor learning outcomes especially concerning the underlying measurement concepts behind the measurement procedures (Smith III, van den Heuvel-Panhuizen, & Treppo, 2011). Although there seems to be a great consistency about the aspects of those concepts (Barrett, Sarama, & Clements, 2017; Lehrer, 2003; Clarke, Cheeseman, McDonough, & Clarke, 2003), differences in the curricula and teaching practice are assumed as well (Lee & Smith III, 2011).

Being interested in cross-cultural differences and similarities in length estimation, we’re looking closer to Taiwan and Germany as first examples, motivated by two aspects: Taiwan and Germany are two examples of very different cultural backgrounds—one Asian and one European country, and both with an official language different from English—and the learning outcomes in both countries differ enormously at 4<sup>th</sup> grade.<sup>1</sup> In contrast to the international results, the preliminary findings of our pilot study on length estimation did not show these differences in the overall estimation abilities. Looking closer to the answers we considered specific differences, which, perhaps, may be explained by different learning opportunities on length learning. Therefore, this textbook analysis serves as a basis for looking to the learning opportunities on length learning in both countries.

---

<sup>1</sup> Although TIMSS 2015 reported significant above average scores for German fourth-graders (overall score: 522, s.e. 2.0; ‘geometric shapes and measures’ score: 531, s.e. 2.5), Taiwanese fourth-graders performed much better (overall score: 597, s.e. 1.9; ‘geometric shapes and measures’ score: 597, s.e. 3.0)

## **Theoretical background**

### **Core concept of lengths and its measurement**

Length understanding, length measurement, and length estimation are thought to be a complex concept with different conceptual underpinnings as well as concrete actions. According to Lehrer (2003), Clarke et al. (2003), Stephan and Clements (2003), and others the most important foundations are

- (1) Understanding of the attribute and its relation to the units used to measure with.  
A length must be understood as the distance between two points in the space. The length of an object can be found by quantifying the distance between its endpoints.
- (2) Logical operations: conservation and transitivity.  
The length of a given object isn't dependent on its location, nor is it variant under special transformations, whereas other transformations don't conserve the length. The transitivity of the equivalence and order relation are one basis for the comparisons of lengths.
- (3) Mental partitioning into parts.  
Being able to partition the length of an object mentally and being sure that adding the measures of the parts will give the length of the whole.
- (4) Iterative tiling with identical units and counting them.  
The measuring process consists of using a unit (standardized or non-standardized) iteratively by placing it end to end without gaps or overlaps. Whether a subdivision of the unit is necessary depends on the precision the measurer looks for.
- (5) Numerical interpretation of the iteration process.  
Either every iteration-step has to be counted during the process, or the number of different identical units can be counted at the end of the tiling-process. The counted number has to be understood as the measure.
- (6) Understanding of measurement tools.  
The children need not only the procedural knowledge how to measure and draw with a ruler, but they need to understand the scaling itself. Crucial is the difference between a point on the scale and the length measured, being asserted to the distance between two scale-points.
- (7) Measures as the relation between unit and number.  
The relation between the unit and the number of units needed to tile a length is inversely proportional. Besides this children have to learn the conventional conversions between different standardized units, including fractions and decimals.

### **Conceptual and procedural knowledge in length measurement**

In the literature, it has been stated since a long time that measurement learning is much more concentrated on superficial procedural aspects than on the underlying concepts (e.g. Lehrer, 2003; Stephan & Clements, 2003). In sharpening the meaning of conceptual and procedural knowledge in measurement learning, the STEM research group at Michigan State University (e.g. Lee & Smith III,

2011, Smith III, Males, Dietiker, Lee, & Mosier, 2013) developed iteratively a coding scheme with conceptual, procedural, and conventional codes. They included all measurement actions children are asked to carry out into the term ‘procedures’ and ‘procedural knowledge’, whereas they use ‘concepts’ and ‘conceptual knowledge’ “to designate the general principles that underlie and justify procedures” (Smith et al., 2013, 399). The third category, ‘conventional knowledge’ was used to code aspects, which are contingent and culturally defined, like the metric of units or aspects of rulers etc.

Their analysis of three US and one Singapore textbook series showed strong emphasis on procedural aspects in all grades and both countries (Lee & Smith III, 2011). If concepts are focused and explicitly addressed, they are not in line with the procedures but appear much later in the curriculum (Smith III et al., 2013).

### **Length estimation**

In the sense of Bright (1976) we consider length estimation as being a mental process of determining a length for an attribute without the aid of measurement tools. Although children’s estimates in length are more accurate than in other measurement areas (Joram, Subrahmanyam, & Gelman, 1998), children are even worse in estimating than in measuring lengths. Researchers stress the importance of strategies (Jones, Taylor, & Broadwell, 2009; Huang, 2015) and their conjectures to the underlying measurement concepts and procedures. Different learning environments based on different curricula might lead to different knowledge (e.g., different estimation strategies). Since most studies on estimation focus on one country with the underlying assumption that the curriculum for measurement estimation will be similar across countries (Jones et al., 2009; Ruwisch, Heid, & Weiher, 2017), we try to get deeper insights into similarities and differences in the lengths curriculum and its focus on learning length estimation. The study of the STEM-project only referred to length estimation at the edge. Nevertheless, they reported great differences in the frequencies among the three US textbook series, and concluded that “despite the frequent calls to estimate lengths, little attention was given in any curriculum to specify the estimation process” (Smith III et al., 2013, 416).

### **Research questions**

The purpose of this study was to examine similarities and differences in Taiwanese and German elementary written textbooks concerning the treatment of length understanding, measurement, and estimation. Specifically, we were interested in those aspects which may lead to different understandings of length estimation.

Q1: On a coarse and organizational level: Are there differences in the main syllabus—number of units, instructional time—on length learning between Taiwan and Germany?

Q2: Do procedural aspects also dominate the Taiwanese and the German curriculum as it has been reported from the USA and Singapore?

Q3: Which concrete differences in the opportunities to learn length understanding, measurement, and estimation can be observed between Taiwan and Germany?

## Method

### Choice of written curricula and scope of analysis

In both countries, elementary school mathematics textbooks were developed on the curriculum guidelines for compulsory mathematics education mandated by the responsible ministry that has them licensed (Lan 2005 in Chinese for the Taiwanese procedure; Stöber 2010 in German for the German procedure). We examined four German elementary textbook series and three from Taiwan which were chosen by the ranking of publishers (see Ruwisch 2017).

A primary textbook series in both countries normally includes a package for each grade. Since the additional materials differ from series to series and are optional for a teacher, the only materials included in our analysis are the main textbooks for each grade.

### Locating the length content

For the purpose of this comparison, we focused on those pages of the textbooks that were designated as length measurement units by the authors, excluding the units involving perimeters of shapes. So our analysis was a first step to come to a deeper analysis as such of Lee and Smith III (2011).

### Coding process of the length content

For coding the different aspects of length content we adopted the coding scheme of Lee and Smith III (2011, 689). We also differentiated between conceptual and procedural knowledge. The analysis presented here is coarser than the very fine one of Lee and Smith III in one sense and broader in another one: The coding unit was not the sentence or question but normally the task, which could contain more than one sentence. Sometimes, there were two different requests in only one sentence. As a consequence, some tasks got more than one code, although normally we tried to decide which element is more important in a special situation. Therefore, we restricted ourselves to tendencies here. In applying the scheme to our data, we also needed to extend the coding scheme. *BL* was added as a conceptual element for tasks that ask students for exploration and learning the measures of benchmarks or personal reference objects for estimation. *CS* is a conceptual code for the definitions of curve versus straight line. A category for reasoning and justification was added (*RJ*), which we think is a linking category between conception, procedure, metacognition, and language.

Exemplary for our differentiation between the procedure and the underlying concept we look closer to “unit conversion”. If the task asked the child to “write the measures given in mm”, this was coded with the procedural code “unit conversion”. If a short description or definition of conversion was given—“Sometimes the unit centimeter is too rough. We then need the finer unit millimeter. 1 cm = 10 mm; 1 m = 1,000 mm.” — we coded this with the conceptual code “units can be converted”.

## Results

### Syllabus, units and time

In Taiwan, the learning of length measurement starts at the first semester of grade 1 in all textbook series. In every grade, length measurement units are included in the textbooks. Whereas in grades 1

and 2, two length measurement units are allocated in every textbook series—one per semester—, only one unit is included in all series for grade 3 and 4, respectively.

Most schools in Germany start length learning in second grade. Only *Das Zahlenbuch* gives an opportunity for learning length measurement in grade one, but only by one page in a book of 132 pages. Nearly every textbook contains one special unit about length learning per grade—with the exception of *Das Zahlenbuch*, which offers two units in grade three and none in grade four.

Table 1 gives detailed information about both countries. On the one hand, the total numbers of pages on length measurement in the Taiwanese textbooks are more than three times of those contained in the German textbooks. On the other hand, comparing the intended instructional time in both countries does not reflect this great difference. German teachers seemed to be asked to refer for a longer period of teaching time to the same page of the textbook.

Grade	German textbook series				Taiwanese textbook series		
	Denken und Rechnen	Flex & Flo	Welt der Zahl	Zahlenbuch	Han-Lin	Kuang-Hsuan	Nan-I
1	—	—	—	1/132 = 0.75% (no time given)	14/224 = 6.25% 6 (240 min.)	15/218 = 6.9% 7 (280 min.)	15/238 = 6.3% 6 (240 min.)
2	10/133 = 7.5% ~10 (450 min.)	6/148 = 4% ~10 (450 min.)	2/133 = 1.5% ~5 (225 min.)	3/132 = 2.3% (no time given)	22/256 = 8.6% 10 (400 min.)	19/219 = 8.7% 10 (400 min.)	21/246 = 8.5% 10 (400 min.)
3	7/117 = 6% ~ 8 (360 min.)	8/156 = 5% ~ 8 (360 min.)	9/125 = 7.2% ~ 8 (360 min.)	7/132 = 5.3% (no time given)	13/268 = 4.85% 5 (200 min.)	8/260 = 3.1% 4 (160 min.)	9/258 = 3.5% 5 (200 min.)
4	3/117 = 2.6% ~ 8 (360 min.)	5/144 = 3.5% ~ 4 (180 min.)	4/125 = 3.2% ~ 8 (360 min.)	—	7/276 = 2.5% 2 (80 min.)	9/256 = 3.5% 5 (200 min.)	11/278 = 4% 6 (240 min.)
Total	20/500 = 4% ~ 26 (1170 min.)	19/596 = 3.2% ~ 22 (990 min.)	15/416 = 3.6% ~ 21 (945 min.)	11/528 = 2.1% (no time given)	56/1024 = 5.5% 23 (920 min.)	51/953 = 5.4% 26 (1040 min.)	56/1020 = 5.5% 27 (1080 min.)

Note: The first row gives the proportion by the number of pages: Pages of the length measurement unit in proportion to the whole number of pages. The second row gives the intended teaching time for the units.

**Table 1: The opportunities for learning length measurement**

In both countries, most time for learning length is spent in second grade. The comparison between both countries suggests that length learning in Germany seems to be more concentrated than in Taiwan: starting in second grade and offering only one unit per grade.

### Conceptual versus procedural affordances

In the German textbooks, the total numbers of conceptual codes were nearly the same in all four series, whereas the number of procedural codes differed. *Das Zahlenbuch* and *Welt der Zahl* got twice as many procedural codes than conceptual ones, *Denken und Rechnen* and *Flex & Flo* got three times as many procedural as conceptual codes.

The Taiwanese textbook series showed little differences in the total numbers of procedural elements, but differed in the number of conceptual codes. Whereas *Kuang-Hsuan* and *Nan-I* were about close in the number of conceptual codes, the third series, *Han-Lin*, only contained about 60 % of the number of *Kuang-Hsuan*, the series with the most conceptual elements. Therefore, this textbook series (*Han-Lin*) contained more than twice as many procedural than conceptual elements. The other two have about one third more procedural than conceptual elements.

Thus, in the German and the Taiwanese curriculum also the procedural affordances dominate, a tendency which is stronger for the German than the Taiwanese textbook series.

## Main categories of conceptual and procedural affordances

The main concepts in all German textbook series are *benchmark learning* and *reasoning and justification*. The latter normally is combined with benchmark learning (more conceptual) or with proportional reasoning as in distance-time-relationships and scale (more procedural). The third most common conceptual category is *units can be converted*, normally at the top of a page, on which the students are asked to convert units in the following tasks.

The main concept involved in all Taiwanese textbook series is *units can be converted*. It occurs about twice as often as *reasoning and justification*, which is the second important conceptual element. Although *benchmark learning* occurs as the third often coded element of conceptual categories in Taiwanese textbooks, it is much rarer than the other two.

Looking to the procedural elements, the most common one in all series of both countries is *conversion of units*.

We differentiated between those procedures that ask for a concrete measurement action, and more abstract procedures, which are presented on the symbolic level. In German textbooks only about one third of the tasks asks for concrete procedures, another third for the *conversion of units*, and the last third for other symbolically presented procedures. In Taiwan nearly one half of the coded tasks ask for concrete and the other half for more abstract procedures, if *conversion of units* is included in the latter one.

Concerning the concrete procedures the most common one in both countries was *measure with a ruler*, when the object is shorter than the ruler. In Germany *draw with a ruler* (also objects shorter than the ruler) and *visual estimation* were the second and third common ones, whereas in the Taiwanese textbooks *measuring with sufficient non-standard units* and *visual estimation* and different kinds of *direct and visual comparisons* were found more often than drawing activities. No *direct comparison* was coded in the German textbooks.

The most common abstract procedures in the Taiwanese textbook series were generating the *sum and differences of length given through word descriptions and representations*, and doing so *given word descriptions only*. In Germany, *word problems with lengths*, sometimes *with the aid of a representation*, also dominate the abstract procedures—besides the conversion of units—, followed by *the comparison or order of length which were given in a symbolic*.

## Discussion and conclusion

The analysis showed similarities and differences between the countries as well as between the textbook series concerning the opportunities for learning length understanding, measurement, and estimation.

Although all textbooks show a dominance of procedural aspects over conceptual elements, this tendency is stronger in the German textbooks. The Taiwanese textbooks focus much more on conceptual elements than the German did. If this difference in the frequency of the opportunities to understand length measurement is crucial for better results in international comparative studies,

needs further investigation. As a first step, our analysis itself can be deepened insofar that we will look, if and how the procedural and underlying conceptual knowledge elements are temporally interlocked or decoupled like in the US textbooks (Smith III et al., 2013).

Although *units can be converted, reasoning and justification* and *benchmark learning* are the most common conceptual elements in both countries, their importance differs. The Taiwanese textbooks mainly stress the idea of conversion, whereas the German textbooks focus more on benchmark learning. Although there were only a few problems involving ‘visual estimation’ as a procedure, we did not yet deepen our analysis in this point to get to know, if the content of this request differs in both countries: Is the procedure itself specified? And if so, how? Is a specific strategy shown? Benchmark knowledge and estimation strategies are seen as crucial elements for good length estimation (Jones et al., 2009; Joram et al., 1998; Huang, 2015).

The comparison of procedural elements showed that both countries very often focus on unit conversion, measuring with a ruler, and addition and subtraction of length. In the Taiwanese textbooks more tasks ask for direct comparison and measurement with nonstandard units, whereas the German textbooks stress visual estimation. Overall, the Taiwanese textbooks ask much more for concrete actions, whereas the German textbooks stress more abstract and mental procedures. How are these results connected to length understanding and estimation abilities?

In concluding these preliminary findings we have to point out that we ourselves are examples of cultural differences. Up to now, every person coded the textbooks of her own country. So the coding procedure has to be done vice versa or perhaps with a person who can translate Chinese directly to German. We also want to broaden and deepen our analysis to get a better understanding of the differences. If we take a broader corpus besides the textbooks, we may get a deeper insight in the differences how teachers and students work with the textbooks in both countries, and how the denser curriculum in the German textbooks is implemented differently from the Taiwanese in classrooms. A much deeper analysis with regard to the coding scheme of Lee and Smith III (2011) as well as qualitative analyses may help to get a better understanding of the so far superficial suggestion that German length learning is more abstract and mental than the Taiwanese one and may result in other length estimation abilities.

# A Hypothetical Learning Trajectory for the learning of the rules for manipulating integers

Jan Schumacher and Sebastian Rezat

Paderborn University, Germany; [jan.schumacher@math.upb.de](mailto:jan.schumacher@math.upb.de); [srezat@math.upb.de](mailto:srezat@math.upb.de)

*In this paper, we first outline a Hypothetical Learning Trajectory (HLT), which aims at a formal understanding of the rules for manipulating integers. The HLT is based on task formats, which promote algebraic thinking in terms of generalizing rules from the analysis of patterns and should be familiar to students from their mathematics education experiences in elementary school. Second, we analyze two students' actual learning process based on Peircean semiotics. The analysis shows that the actual learning process diverges from the hypothesized learning process in that the students do not relate the diagrams on the different levels of the task sequences in a way that allows them to extrapolate the rule for the subtraction of negative numbers. Based on this finding, we point out consequences for the design of the tasks.*

*Keywords: integers, negative numbers, permanence principle, induction extrapolatory method, hypothetical learning trajectory, semiotics, diagrammatic reasoning*

## Introduction

The difficulties and obstacles related to the concept of negative number and their operations are well documented in the history of mathematics (Hefendehl-Hebeker, 1991) and a growing body of recent research (e.g. Schindler, Hußmann, Nilsson, & Bakker, 2017).

According to Steinbring (1994, p. 279) the notion of negative numbers and the related understanding of their manipulations require autonomous and formal rules, which are comparable to the rules of algebra. He argues that the consistent system of rules for manipulating negative numbers is neither deduced from reality nor is it directly applicable to real world contexts, in which numbers represent magnitudes. According to Hefendehl-Hebeker (1991, p. 30), it was not until the 19th century that these obstacles were overcome in the history of mathematics by a shift of view:

The change consisted in the transition from the concrete to the formal viewpoint. Subsequently, the concept of number could be introduced in a purely formal manner without consideration of the concept of magnitude.

Therefore, a full understanding of the rules for manipulating negative numbers might be not achievable by referring to real world contexts, such as assets and debts or temperature, in which negative numbers are easily perceived as magnitudes. The introduction of negative numbers might also require a shift from the concrete to the formal viewpoint.

Our overarching aim is to understand how students make sense of negative numbers and their manipulation rules in a Hypothetical Learning Trajectory (HLT), which aims at such a mathematical understanding of these rules from a formal viewpoint. The different meanings of the minus sign as unary, binary or symmetrical present a particular obstacle for students (Vlassis, 2004), which

becomes most evident related to the subtraction of negative numbers. Therefore, we focus on the question how students can develop a formal understanding of the rule for subtracting negative integers in this paper.

We first outline a HLT for the learning of the rules for manipulating integers, which aims at such a mathematical understanding of these rules from a formal viewpoint. Second, we give a first insight into students' actual learning processes related to subtracting negative numbers.

## Theoretical Framework

According to the seminal definition by Simon (1995) a Hypothetical Learning Trajectory (HLT) “consists of the goal for the students' learning, the mathematical tasks that will be used to promote student learning, and hypotheses about the process of the students' learning” (Simon & Tzur, 2004, p. 93). A HLT “is based on the understanding of the current knowledge of the students involved” (Simon & Tzur, 2004, p. 93).

The goal of our learning trajectory is that students develop an understanding of the rules for manipulating integers from a formal viewpoint, i.e. to understand that the calculation laws for integers are defined the way they are, because they “are uniquely determined as extensions of certain laws governing the positive numbers” (Freudenthal, 1983, p. 434). Freudenthal called this the “algebraic permanence principle” and propagates the “induction extrapolatory method” (Freudenthal, 1983, p. 435) in order to introduce the negative numbers. Our HLT draws on this method. The tasks we used to implement this method relate to students' prior experiences, because we use task formats that are familiar to students from the learning of arithmetic in elementary school. As pointed out earlier, we do not use real-world contexts, since the rules for manipulating integers are not deducible from them. Therefore, our notion of understanding refers to what Wittgenstein has termed the sign game, in which “the meaning of the signs, symbols, and diagrams does not come from outside of mathematics but is created by a great variety of activities with the signs within mathematics” (Dörfler, 2016, p. 27). In our case, the meaning of the signs is explored in what Pierce (1976) calls “diagrammatic reasoning”.

According to Dörfler (2005, p. 58) diagrams in the sense of Pierce are inscriptions, which have a specific structure depending on the relationships among their parts and elements. Based on their structure diagrams are the objects of rule governed operations. These operations allow to transform, compose, decompose, and combine the inscriptions and can be called the “internal meaning of the respective diagram” (Dörfler, 2016, p. 25). Diagrammatic reasoning according to Peirce then is

reasoning which constructs a diagram according to a percept expressed in general terms, performs experiments upon this diagram, notes their results, assures itself that similar experiments performed upon any diagram constructed according to the same percept would have the same results, and expresses this in general terms. (Peirce, 1976, pp. 47-48)

Summarized, it “is a rule-based but inventive and constructive manipulation of diagrams for investigating their properties and relationships” (Dörfler, 2016, p. 26). Though they are rule-based the manipulations are still imaginative and creative and not just mechanic or purely algorithmic (Dörfler, 2016, p. 26).

## A HLT for the learning of manipulating negative numbers
