The examples below show the models that two different pre-service teachers at the University of Cordoba (Spain) proposed for solving two released items from the PISA 2003 framework (OECD, 2006). The analyses were carried out following the S-R-M strategy explained above, by first focusing on the elements received by the pre-service teachers and secondly on what the pre-service teachers contributed, with special attention paid to the premises and deductions in the analysis of the used mathematization (M). The results of the analyses are summarized in Figures 2 and 3.

**Example 1:** Antarctica (Figure 2). The student does not contribute any elements to the system (S). She mostly bases her answer on the picture and provides some verbal reasoning. There are no explicit

mathematical concepts, although she implicitly uses the extensive nature of the area. She estimates the area of Antarctica as a portion of an imaginary squared surrounding the island. This approximation is a premise, which shows no clue about how she would proceed for an island with different shape.

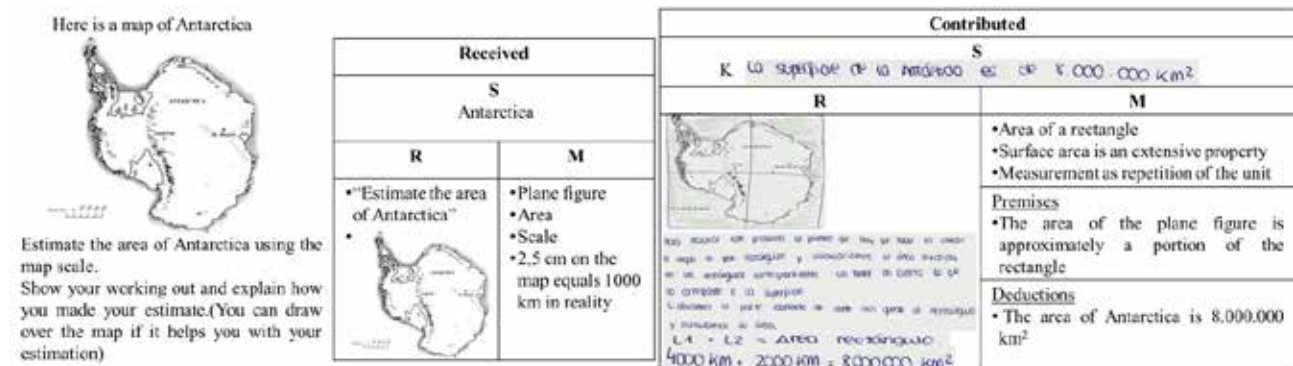

Figure 2: Proposed analysis for a given answer to the task "Antarctica"

**Example 2: Pizzas** (Figure 3). The student does not contribute any explicit element to the system. However, he tacitly introduces the value for money notion when he states "with one zed, I am buying a portion of 31,416 cm<sup>2</sup>". He mostly uses symbolic representation. The premises are relevant because he (i) identifies that the relation diameter-area is not linear and (ii) recognizes the area as the correct variable for estimating the best value for money. This is evidence of a possible general procedure to apply for other kind of sizes of pizzas.

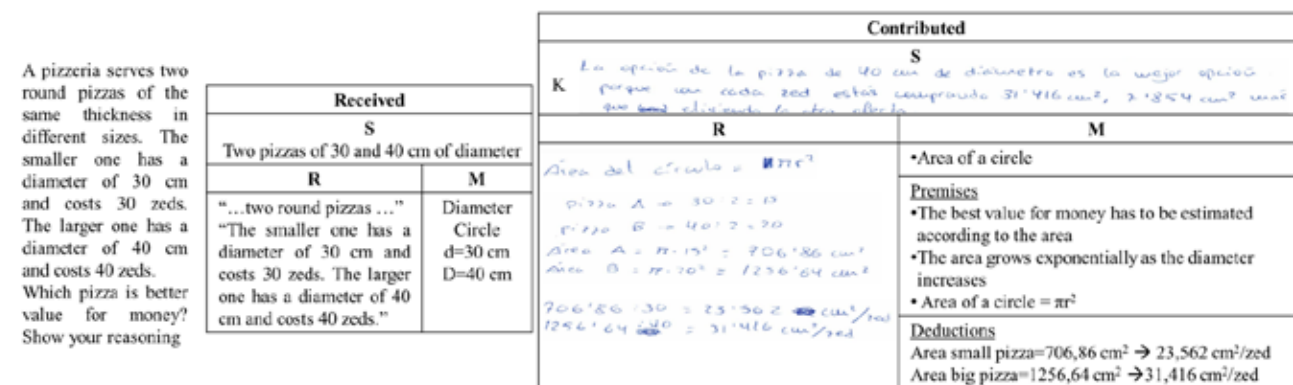

Figure 3: Proposed analysis for a given answer to the task "Pizzas"

## Discussion

We now turn to discuss some of the aspects and features of the provided definition of the notion of mathematical model in this paper. Firstly, readers should note that the components of a model are not specified univocally in the formal nature of the definition (Velten, 2009). This is intentionally done in order to let each researcher specify the meanings of each component according to his/her various needs.

Secondly, when dealing with the components S, M, and R of the definition, these should be understood as inseparable elements. In this way, the definition is applicable from different perspectives and at different levels of abstraction. In Mathematics Education, S very often depends on the task context (which may be mathematical or extra-mathematical). Therefore, S is susceptible to empirical or conceptual experimentation. In turn, R contains the evidences of the application of the

model in specific cases. Particularly, *R* captures the representations of the knowledge of the system obtained by the model creator and represents the source of information for the analysis of the models linked to tasks. This is the reason why *R* should be of special interest for research in mathematics education. Finally, *M* contains information about the level of abstraction of the model. *M* is not limited to a conceptual structure or a set of affirmations. As Niss (2012) pointed out, *M* contains a large number of objects, relationships, properties, results, hypotheses and ways of reasoning that enable understanding of the evidence collected in *R*. Subcategories within *M* (premises and deductions) are specified to provide a better understanding of the model. Premises offer information about how the modeller conceives the system and what mathematics can be applied to get knowledge of relevance to *S*. On the other hand, deductions show the way of reasoning and the conclusions obtained. By combining the analysis of both elements, the researcher is able to identify whether there is an underlying general model. It should be pointed out that premises are sometimes not evident to identify and that they have to be conjectured based on the collected information. For instance, in the example of Antarctica, it is difficult to identify the premises used by the student to create her model. Nevertheless, the student in example 2 provides evidence that he would be able to tackle the task given pizzas of different prices, shapes and sizes.

Thirdly, we provide a comment on the role played by the question or problem posed. Velten (2009), in engineering, emphasized the importance of including the problem to be solved (*Q*) within the model. From Velten's perspective, without including a question about the system, the model would not emerge. However, we decided not to include this element (the question) in our model definition for simplicity reasons and also because we consider a model as an instrument used to generate knowledge, and hence to go beyond specific problems (Chevallard, 1989). Furthermore, the same model is able to answer different questions in a system (for instance, Cuisenaire's strips are useful to answer different arithmetic questions). On the other hand, the knowledge generated (*K*), which includes possible answers to *Q*, can be seen as belonging to the model, namely as part of *S* since *K* establishes relationships within the system which were previously unknown (see Figure 1 for different relationships between *Q*, *K*, *S*, *M* and *R* within the framework of the proposed definition).

Fourthly, the potential of the proposed definition to be a flexible analysis tool should also be highlighted. As indicated above, the system *S* and its conceptual mathematization *M* may contain very diverse elements and relationships. Hence, it is natural to establish subcategories for the exploration of the elements of *S*, *R* and *M* in order to obtain a greater depth in the analysis. However, the generality of the definition prevents establishing univocal criteria *a priori* to discriminate between different types of entities in the analysis. These reasons led to the establishment of broad categories. However, as discussed above, subcategories were only included in the study of *M*, but in any case, when required, the scheme (*S*, *M*, *R*) does admit that particular subcategories are developed to specify a finer categorization or a hierarchy of properties associated with the system under study.

Finally, it is important to draw attention to the specific character of the proposed definition for research in mathematical education. Especially two properties may be highlighted: (1) The inclusion of *R* as a component of the mathematical model (Lesh & Harel, 2003). This element, not considered in other areas, is essential in education, since most of modelling performed in school mathematics consists of choosing a suitable representation (a manipulative material, the number line, a tree

diagram in probability); (2) The application of the model with the focus on the student's activity. When considering the part received and the part contributed by the student, the definition seeks to make the contribution explicit, differentiating the information of S and representations provided (the statement of a task, for example). This distinction also has didactic applications enabling to control the task variables and generate situations of different difficulty within the same system.

## Conclusions

This paper provides a definition that includes all the elements a mathematical model should possess according to our literature review. The novelties of this approach are the focus on the model, instead of on the process or the competencies (like in most of the background literature) and the functional nature of the definition provided, which has been exemplified and discussed throughout the paper.

Regarding the elements that comprise a mathematical model and how they can make up a functional definition, this proposal combines three inseparable elements which, as a whole, account for a mathematical model from different levels of abstraction. A system, S, that includes elements of the context; its mathematical conceptualization, M; and the set of representations, R, that a student uses to describe S, M and to work mathematically. Each of these components provides flexible focus of attention for research and an internal logic that offers an analytical strategy suitable for the analysis of modelling in schools. The main advantage of this definition lies in its applicability for the analysis of scholar models. Its disadvantages are also related to its operational nature: on one hand, at least 6 categories must be distinguished to define a model; on the other hand, the desirable idea of a model as a mapping between reality and mathematics (Niss, 2012) then becomes diluted.

We expect that our proposed definition not only is functional, but also general (applicable to a wide range of modelling scenarios). Future research will need to focus on this and of analyzing the effectiveness and usefulness of the given proposal, as well as its applicability to different contents and educational levels. In addition, also the potential didactic applications need to be explored in future work.

# The extended theoretical framework of Mathematical Working Space (extended MWS): Potentialities in physics

Laurent Moutet<sup>1</sup>

<sup>1</sup> Laboratoire de Didactique André Revuz, UFR de mathématiques, Université Paris Diderot, Paris, France; [laurent.moutet@ac-amiens.fr](mailto:laurent.moutet@ac-amiens.fr)

*The aim is to show how the extended Mathematical Working Space (extended MWS) theoretical framework makes it possible to analyse the tasks implemented during a few stages of a modelling cycle in physics. The study begins with a special relativity teaching sequence using a diagrammatic approach in “Terminale S” in France (Grade 12). The analysis using the extended MWS theoretical framework allows to highlight the learning advantages of this diagrammatic approach during a complete didactic engineering. This work is proposed for TWG6 to CERME11.*

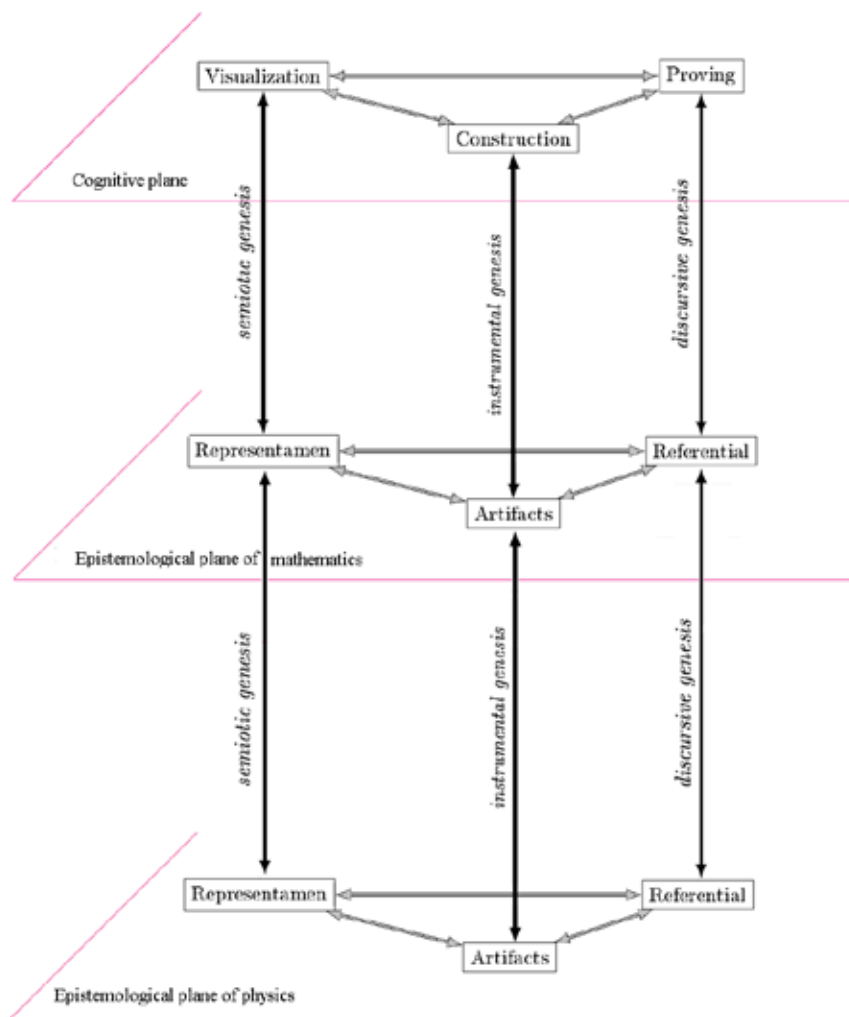

*Keywords: Mathematics, physics, extended MWS, modelling.*

## Presentation of the extended MWS theoretical framework

The Mathematical Working space (MWS) was developed to better understand the didactic issues around mathematical work in a school environment by Kuzniak, Tanguay, and Elia (2016). The MWS has two levels: one of a cognitive nature in relation to the student and another of an epistemological nature in relation to the mathematical content studied. The epistemological plane contains a set of representations (signs used), a set of artefacts (drawing instruments or software) and a theoretical reference set (definitions and properties). The cognitive plane contains a visualization process (representation of space in the case of geometry), a construction process (function of the tools used) and a discursive process (arguments and evidence). Mathematical work results from an articulation between the cognitive and epistemological planes through instrumental genesis (operationalization of artefacts), semiotic genesis (based on the register of semiotic representations) and discursive genesis (presentation of mathematical reasoning). The different phases of mathematical work associated with a task can be highlighted by representing three vertical planes on the ETM diagram. Semiotic-instrumental interactions lead to a process of discovery and exploration of a given academic problem. Those of an instrumental-discursive type favour mathematical reasoning in relation to experimental evidence. Finally, those of the semiotic-discursive type are characteristic of the communication of mathematical results as well as of more elaborate reasoning. The MWS diagram was transformed by Moutet (2018) by adding an epistemological plane corresponding to the rationality framework of physics (Figure 1). It was chosen to keep only one cognitive plane. We hypothesized that students' conceptions in mathematics and physics can be highlighted using a students' personal extended MWS. The functioning of the schemes (Vergnaud, 2013) specific to these conceptions could appear during the activation of the various geneses. The Concepts in mathematics would be highlighted by the activation of geneses, between the cognitive plane and the epistemological plane of mathematics, those in physics would be highlighted by the activation of geneses, between the same cognitive plane and the epistemological plane of physics. A single cognitive plane would therefore be

sufficient to describe conceptions in mathematics, physics and to analyse student tasks from both a mathematics and a physics perspective. The term “proving” is retained, but in the case of the extended MWS, it will take a narrower meaning of justification or reasoning. The extended MWS framework makes it possible to analyse in detail the interactions between the various rationality frameworks, and the student’s cognitive plane and then to qualify the nature of the work accomplished by the student.

The epistemological plane of mathematics studied here concerns Euclidean geometry. The tasks to be carried out are associated with the construction of lines, segments, symmetries parallel to a line, projections passing through a point and parallel to an axis. The epistemological plane of physics is associated with the reference frame of special relativity studied in class. These are the notion of the Galilean reference frame (two reference frames moving in a straight line and at a constant speed with respect to each other), of an event (a point located on a space-time diagram and associated with a position  $x$  and a time  $t$ ), of Einstein’s two postulates, of the notion of proper duration and improper duration as well as the relationship of dilation of durations. Lorentz transformations are not studied in Grade 12.

**Figure 1: Extended MWS Model**

## From the “model situation” to the “real results” during a special relativity modelling

A teaching sequence developed by Moutet (2018) is destined for students in “Terminale S” (Grade 12) on the topic of special relativity following the work of de Hosson, Kermen, and Parizot (2010). It follows the learning of the course, and the correction of exercises in the manual, and participates in the conceptualisation of notions of special relativity, by allowing them to be reinvested in a different and unknown context (Vergnaud, 1990).

Two research questions guided this work: 1) How does the extended MWS framework allow the analysis of the sets of rationality frameworks between mathematics and physics during a sequence dealing with special relativity with “Terminale S” students via a geometric approach? 2) To what extent does the analysis of the use of dynamic geometry software by the extended MWS framework show that it promotes conceptualisation in students?

The teaching sequence can be described in the following context: Armineh drives a car moving at a speed  $v$  near the speed of light relative to Daniel. The latter is on the roadside next to three flash lights  $S_1$ ,  $S_2$  and  $S_3$  associated with three events  $E_1$ ,  $E_2$ ,  $E_3$  and initially known in Daniel's reference frame (Figure 2). An event  $E_i$  corresponds to a coordinate point  $(x_i, c.t_i)$  in the Minkowski space-time diagram.  $S_1$  and  $S_2$  have the same position in Daniel's reference frame.

Figure 2: The “real model” of the situation

We can use the modelling cycle proposed by Blum and Leiss (2005) to position the teaching sequence on the chronological order of events as a function of the reference frame in the context of special relativity. We carried out a preliminary study of a sequence by studying the passage real model  $\rightarrow$  real results with the objective of developing a longer-term sequence covering a complete modelling cycle real situation  $\rightarrow$  real results. In this case, it will not be appropriate to use a “2CV” as a vehicle to favour the passages real situation  $\rightarrow$  situation model and situation model  $\rightarrow$  mathematical results.

We can also take the point of view of Vince and Tiberghien (2000) who studied the articulation between the world of objects and events and that of theories and models in the physical sciences. The objects resulting from the simulation are observable and can be manipulated. They are not real objects or elements of the world of theories and models. They act as intermediaries, facilitating the transition, through the problem-solving activity, between the world of objects/events and the world of models.

The Minkowski diagram is a space-time diagram allowing to know the space-time coordinates of an event in a reference frame of Armineh or Daniel. In the Minkowski diagram, the line  $x = 0$  is described by the axis  $(Oc.t)$  in the Daniel reference frame. Similarly, the line  $x' = 0$  is described by the axis  $(Oc.t')$  in the Armineh reference frame.  $c$  is the speed of light in vacuum or air. Projections on this type of diagram are made parallel to the axes. The axis  $(Ox')$  is the symmetric of the axis  $(Oc.t')$  with respect to the line  $x = c.t$ . It is the same for the axes  $(Ox)$  and  $(Oc.t)$ .

The dynamic geometry software GeoGebra and the Minkowski space-time diagram were used by the students. It represents the reference frame  $(xOc.t)$  relative to Daniel's reference frame and the reference frame  $(x'Oc.t')$  relative to Armineh's reference frame. The latter moves at the speed  $v$  of 0.6 times the speed of light in vacuum with respect to Daniel along an axis  $(Ox)$ . The straight lines  $(Ox)$  or  $(Ox')$  correspond to the route in Daniel's or Armineh's reference frames (Figure 3).

With respect to Daniel, the chronological order of production of the three events is  $E_1$ ,  $E_2$  and  $E_3$  while with respect to Armineh the order is  $E_1$ ,  $E_3$  and  $E_2$ . The GeoGebra cursor allows to modify the experimental conditions by changing the speed  $v$  and thus observe a change of chronological order of events production in the Armineh frame of reference. The corrected activity file with the Minkowski diagram is available by clicking on the following hyperlink: [https://drive.google.com/open?id=0B\\_f8SgBLz2P0N0xfazFCSmU3MHM](https://drive.google.com/open?id=0B_f8SgBLz2P0N0xfazFCSmU3MHM)

The epistemological plane of mathematics and the cognitive plane are mobilised during the construction of the cursor because it is necessary to know how the  $Ox'$  and  $Oc.t'$  axes are modified according to the speed  $v$ . The two axes are symmetric with respect to the line  $x' = c.t'$  which is also confounded with the line  $x = c.t$ . The epistemological plane of physics is also mobilised when the students conclude on the chronological order of events according to the two reference frames (Figure 4).

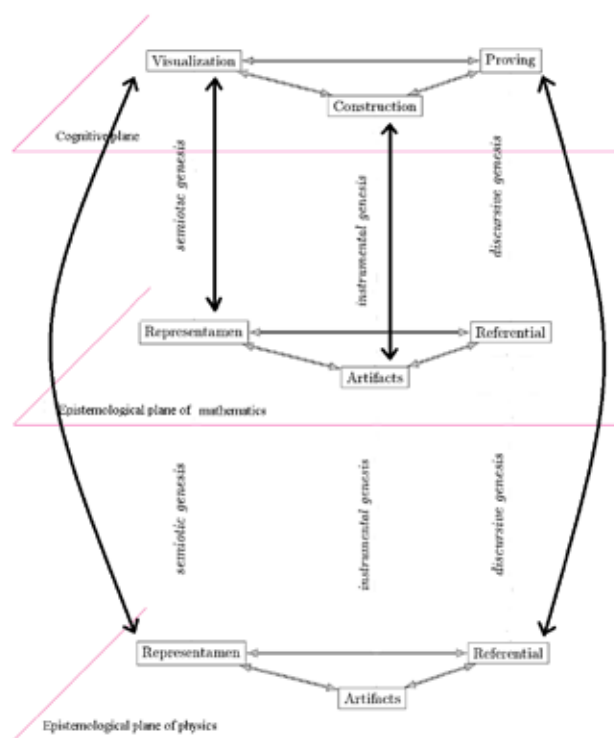

A class of 34 students from a secondary school in Picardy participated in the experiment. A first paper-pencil session was performed to construct and use the Minkowski diagram with strong teacher guidance. The work focused on the phenomena of time dilation for a given speed from one reference frame to another. The activity, corresponding to the second session, was then given to groups as a homework. The speed conditions were different from one group to another. The students had to model in autonomy the situation where the speed of one reference frame compared to another is modified and close to the speed of light. It was therefore necessary to use dynamic geometry software in autonomy, build the dynamic Minkowski diagram and deduce results on the chronological order of events according to the reference frames. Most students had not used GeoGebra software in high school. The students completed a first version of their homework assignments, and then worked for two hours in half class in the computer room to finalise their

GeoGebra file. Each student also made an MP3 recording to summarize the entire sequence, which totalled five hours. The work of four students was analysed, and they were selected based on their academic performance (success and difficult students).

**Figure 3: The mathematical model of the situation**

With the MWS extended model we can perform a priori analysis of each of the tasks to be executed by the students. The level of difficulty of each task, can be appreciated by looking at the portion of the genesis instrumental-discursive or semiotic-discursive, more difficult, compared to the genesis semiotic-instrumental. A posteriori analyses allow us to study the tasks assigned to the students, and those carried out by them, considering the rationality frameworks of mathematics and physics. This study focused on the links between epistemological and cognitive planes. It led to the identification of the sets of rationality frameworks when solving this problem of special relativity treated by a diagrammatic approach. The dynamic geometry software GeoGebra allows to perform an additional semiotic genesis with its dynamic aspect. The cursor allows the speed conditions to change from one reference frame to another and the student can see the results directly on the screen. An instrumental genesis different from the paper-pencil activity, is also used during the construction of the Minkowski diagram. Finally, we hypothesise that GeoGebra, by making it easier to make conclusions about the relative chronological order of events, leads to the activation of an original discursive genesis. The audio recording, which the students made to summarise all the tasks performed during this sequence, allows them to communicate on the Minkowski diagram without directly implementing it. It is the sign of semiotic and discursive interactions favouring a conceptualisation of notions of special relativity.

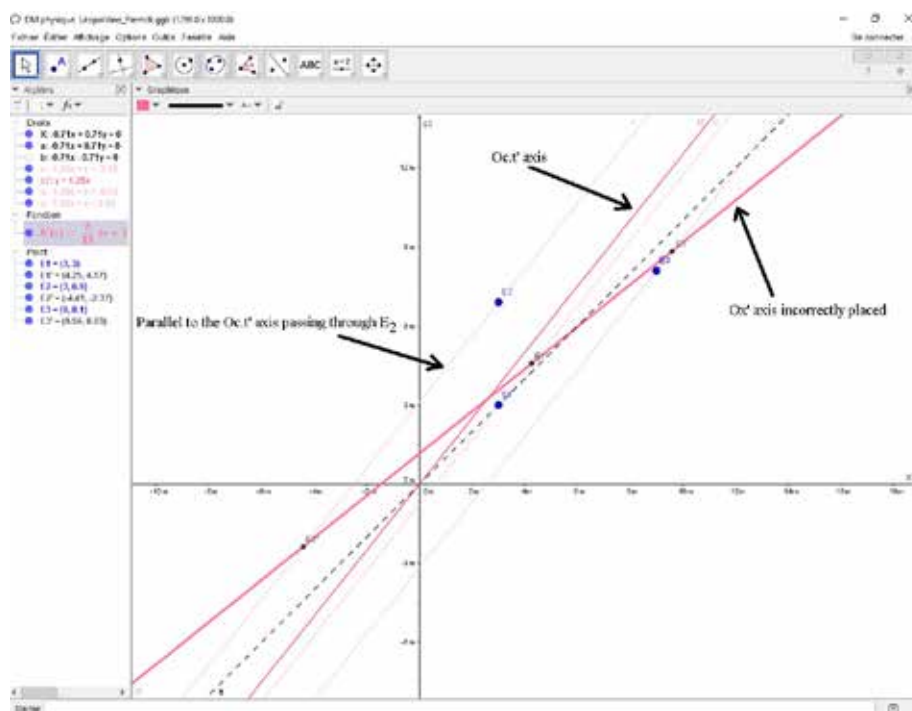

**Figure 4: A priori analysis of cursor usage with GeoGebra**

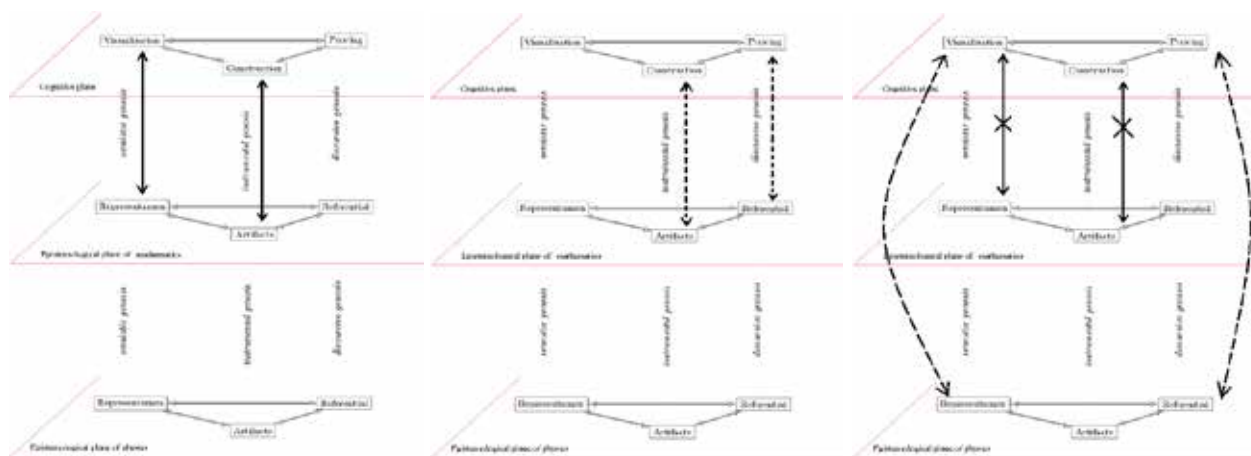

Student B's work is presented here. The Minkowski diagram includes the three events, the  $Ox$ ,  $Oc.t$ ,  $Oc.t'$  axes, the  $x = c.t$  line, and projections parallel to the  $Oc.t'$  axis cutting an  $Ox'$  axis that is not correctly positioned. Also, the cursor does not appear. The notion of event seems to be mobilised as well as that of reference frame since the two reference points appear explicitly even if it remains imperfect. The notion of relative chronological order does not seem to be a well-known one (Figure 5).

The second version which has been reworked in class (personalised help from the teacher to give technical information on the cursor and on the meanings of the lines  $x = c.t$ . or  $x' = c.t'$ ) includes the different elements which were missing in the first version. The  $Ox'$  axis is well positioned, the cursor for changing the  $v/c$  value appears and the  $c.t$  coordinates of the different events also. Parallels to the  $Oc.t'$  axis or to the  $Ox'$  axis passing through the different events are also represented.

This work highlights tasks described by semiotic-instrumental interactions, properly performed by Student B and more marginally tasks described by instrumental-discursive interactions. Important confusions are shown in the audio recording, on the construction of the line  $Oc.t'$  with an incorrect coefficient director (coefficient director of 0.6 instead of  $1/0.6$  when  $v = 0.6.c$ ). This recording also shows that Student B is saying results without using the Minkowski diagram or in a basic way. There is confusion about the goal of the activity (comparing speeds from Student B), or about the notion of the speed of a system in a given reference frame (Student B speaks rather of the speed of a reference frame). The explanations of the plot of the line  $x = c.t$ . are ambiguous as the positions of the  $c.t'$  coordinates of the various events (Figure 6).

**Figure 5: Screenshot of the first GeoGebra version of Student B**

**Figure 6: A *posteriori* analysis of the tasks performed by Student B**

The black arrows describe a genesis on the extended MWS corresponding to a correctly performed task, the black arrows crossed out an incorrectly performed task and the dotted arrows, a partially successful task.

## Conclusion

The extended MWS framework, allowed us to analyse the tasks associated with certain stages of the modelling cycle in a problem involving special relativity. It considers the mobilisation of the epistemological planes of mathematics, and/or physics for each of the tasks requested. The extended MWS framework also led us to show that the GeoGebra software develops specific geneses in relation to a paper-pencil activity. A new semiotic genesis leads to a visualisation of the change in the time coordinates of events as a function of Armineh's speed  $v$  with respect to Daniel. A new

instrumental genesis corresponds to the manipulation of the dynamic geometry software, with the cursor functionality allowing to simply change the experimental conditions. Finally, a new discursive genesis makes it possible to conclude on the chronological order of events, according to the reference frame of study and the speed  $v$ . The extended MWS model leads to an *a priori* analysis of each of the tasks to be performed by the students and to a successful *a posteriori* analysis of the work performed by them. We then plan to analyse, using the extended MWS model or one of its evolutions, the tasks implemented at each stage of the global modelling cycle during other sequences using special relativity. Preliminary results tend to show that the genesis as well as the epistemological plans of mathematics and physics are not mobilised in the same way according to the stage of the modelling cycle, and that the teacher often, assumes implicitly an important part of the stages of the modelling cycle (we suppose an important assumption of responsibility for the stages going from the real situation to the real model), which does not help “in our opinion” the students to understand the problems which are given to them. Problem-solving exercises allow this understanding, but it takes time to complete. We plan to carry out the same study from the point of view of the theory of both worlds, that of objects/events and theories/models. It would thus be possible to finely analyse the passage between the two worlds via the simulated world using the extended MWS model.

# Downscaling and upscaling Fermi problems

Marta Pla-Castells and Irene Ferrando

Universitat de València. Facultat de Magisteri. Valencia, Spain; [marta.pla@uv.es](mailto:marta.pla@uv.es)  
[irene.ferrando@uv.es](mailto:irene.ferrando@uv.es)

*The introduction of modeling tasks in the first grades of primary school requires a deep reflection from the point of view of both the design and the implementation. In this paper we describe an empirical exploratory study developed with the objective of designing a sequence of modeling tasks focused on solving a big numbers estimation problem that, in origin, is inaccessible for students. The key to the design of our sequence is to use a technique that we have called downscaling - upscaling, inspired by heuristic strategies. So, by resizing the initial problem, 2nd grade students are able to tackle a problem that seemed very big using complex mathematical procedures.*

*Keywords: Problem solving, measurement techniques, early childhood education, real context problems, heuristic strategies.*

## Introduction

In the last years, tasks based on real contexts are becoming increasingly important in primary and secondary school curricula. Even so, due to the complexity of carrying out this type of tasks in a classroom, both by teachers and students (Cabassut & Ferrando, 2017), there are few studies that analyze the implementation of this kind of task in the first years of primary school. All this makes of special interest the study of the concepts related to the measurement of magnitudes and the estimation of large quantities in a real context, using the so-called Fermi Problems.

## Theoretical framework

### Fermi problems

Jonas Ärleback (2009) defines Fermi problems as “open, non-standard problems requiring the students to make assumptions about the problem situation and estimate relevant quantities before engaging in, often, simple calculations”. According to the research presented by Ärleback and Albarracín in the previous edition of CERME, this definition is the most used in mathematics education research literature. Here we will focus on a particular kind of such problems: *Big numbers estimation problems* (Albarracín & Gorgorió, 2013).

Twenty years ago, Clements (1999) already claimed that children, in their first experiences with length measurement, should be given a variety of experiences in order to develop measurement strategies. According to Hogan and Brezinski (2003), an important part of teaching measurement concerns the development of estimation. Nevertheless, there are still few studies that refer to the way estimation is worked in primary school classroom (Pizarro et al., 2015).

In previous works, other authors have made experiences based on the use of Fermi problems with students of the higher levels of primary education (Peter-Koop, 2009) and very recently with students of the first cycle of primary education (Gómez & Albarracín, 2017). In the present work we have tried to take advantage of environments close to the students to introduce some elementary concepts

related to the calculation of a magnitude that is often complicated and leads to confusion: the perimeter of a polygon (Mason, Stephen, & Watson, 2009).

### **Modelling sequences**

Ärlebäck, Doerr and O’Neil (2013, p. 316) gave importance to the development of sequences of modeling tasks so that through these sequences students “engage in multiple cycles of descriptions, interpretations, conjectures, and explanations that are iteratively refined while interacting with other students”. In this way, by constructing a sequence of modeling tasks, we can deepen the study of complex concepts in the first years of primary school. Based on the previous works of Pólya (1973) and Stender and Kaiser (2017) we have also focused on the use of heuristic strategies directed by teachers when solving complex modeling tasks. We propose a design of a sequence of tasks based on the heuristics recommendations provided by Pólya (1973, p. xvi): “If there is a problem you can’t solve, then there is an easier problem you can solve: find it.” Stender and Kaiser (2017) affirm that, ideally, students should use heuristic strategies during the modeling process that teachers should convert into strategic interventions. Since our experience is addressed to very young students, our aim is to allow them to approach a complex problem using techniques based on downscaling and up-scaling the original problem as a heuristic strategy.

### **Research objectives**

Our work is in an initial phase. We will give some details about the first phase of an empirical exploratory study where we intend to describe a technique, called downscaling-upscaling, to design sequences of Fermi problems in the first years of primary school. Since this is an early-stage investigation, our objective is limited to: (1) Describe in detail the aspects considered in the design of the sequence of tasks; (2) Describe a qualitative exploratory analysis of the results of implementation with a natural group of second grade students.

### **Methodology. Design of the empirical study**

#### **Sample**

Our study focuses on a natural group of 21 second grade students of primary education who have not yet worked on the concepts of area and perimeter nor have ever faced a modeling task. They have already worked on arithmetic concepts like addition and subtraction but they have very little notions about multiplication. The activity was implemented in May 2017.

#### **Treatment: downscaling – upscaling design of tasks sequence**

The starting point of the activity is a very general question that, a priori, the students are not able to answer. The objective of establishing an initial problem is to observe that a complex problem that seems difficult to tackle – estimate the number of people necessary to surround the town – can be simplified if we try to solve similar smaller problems where the resolution strategies are equivalent. Following Pólya’s heuristics, we propose them to “solve a simpler problem”. In this case, what we try is to reduce (downscale) the scope of the initial question, first to the schoolyard and secondly to their classroom, giving them the opportunity to make measures in a very close context. Once they have attempted a solution of the simpler problem, we foster the generalization of the procedures

developed in the first part of the sequence (there the upscaling process starts). In the following, we give the details of the activities developed during each session of the experience.

1st session: A “Big Problem”. The introductory session aimed exclusively to present to the students the problem to be solved. Thus, this first activity started with an open question that students did not know how to answer: *“If we asked all the inhabitants of Sueca<sup>1</sup> to surround the town by standing next to each other, could they do it or would they have to ask for reinforcements from the people of the next town?”* At this point we just wanted to catch the attention of the students and identify some ideas about perimeter and big numbers conceptions.

2nd session: Progressively reducing the “Big Problem”. The first step was to propose to the students to make a smaller human chain. In this case, they were asked to think about how to estimate the number of students needed to surround the schoolyard. At this point, we just ask them to think about possible strategies to obtain, graphically, a procedure to get an estimation, not to measure or even compute. The second step was to answer to the smallest question: *“How many small wooden cubes do we need to surround a large wooden board?”* Here, we try to show them that the previous problems were the same as this one. In this case, we provide them with manipulative materials in order to foster measure strategies based on the iteration of the unit as explained in Barrett et al. (2011).

3rd and 4th session: We solve the problem of the schoolyard. During the third and fourth sessions, the students worked on the rectangular schoolyard. So, based on the strategies worked on in the previous session, the students would try to solve a bigger problem. They had to estimate the number of students needed to surround the perimeter of the yard. In these sessions, we provide students with one-meter-long ropes.

5th session: We work on scaled ground plans. In order to answer the “Big problem”, it is necessary to introduce the perimeter measurement on scaled plans. Therefore, the fifth session was devoted to work on a scale plan of a relatively small space close to students; a garden close to the school. We asked them to use the ruler and, using the scale and the estimations made in the schoolyard in the previous session, to estimate the number of people needed to surround the yard.

6th session: Solving the big problem. During this session each group of students was given a map in A3 format of the town of Sueca in a grid in order to finally give an answer to the “Big problem”.

### **Data collection and data evaluation**

The experience was organized sequentially through five activities that were carried out over six sessions of 50 minutes. Students worked sometimes individually and sometimes in 4 groups of 4 children and one group of 5 (we will specify this in the following section). The teacher who conducted the sequence had previous experience in modelling activities and was working under the supervision of two researchers. During the group work sessions, we video-taped two groups, and we audio-taped the other groups. In Session 1 and at the end of the Session 6 there were whole group discussions that

---

<sup>1</sup> A Spanish town with around 28000 inhabitants.

were also video-recorded. In our analysis we have also considered the written productions (individual and grouped ones).

Since this is an exploratory study, we are limited to analyze the actions of students' groups to each of the tasks. In fact, the sample is not big enough to establish a grounded analysis. That is why we will not include any quantitative analysis; we'll just describe some aspects that we have considered important for further research. Our objective, at this point, is to identify whether the design of the sequence allows students to face, without blockages, the resolution of each task. We want also to identify, if possible, different strategies for solving equivalent problems and their evolution throughout the sequence. In the following section we summarize the description of the results for each session.

## Description of the results

First session. The objective of this session was to collect general impressions of the students about a problem of estimating a big number. It is not expected that they will base their answers in mathematical arguments. Here are some of the answers collected: *"In the village there are too many people (S1)"*, *"There won't be enough people (S2)"*, *"There are many people who work (S3)"*, *"The planet is very large and we would not be enough (S4)"* and *"If we put one next to the other and put also the dogs and cars, yes we will be enough (S5)"*.

Since students were not asked for more than an unjustified spontaneous response, none of the reflections contain references to neither calculations nor mathematical concepts. This first activity allows us to detect difficulties linked to the understanding of the question (it is not clear in the case of the student S5), problems associated with the concept of perimeter (this we observe, for example, in the answer of the student S4) and the process of obtaining an estimation (response of student S3).

Second session. 1st part: Let's reduce the problem: the schoolyard: *"To surround the yard, are there enough children in this class? Or would we need to ask for help from children in the other classes?"* The students, working individually in the classroom, represented graphically how they would make the estimation. In the productions shown in Figure 1, different schemes are observed. In the third one there is some confusion between the perimeter and the area since the student tries to cover all the space of the schoolyard with children and not just surround its perimeter.

**Figure 1: Some of the schemes made by students in the first part of Session 2**

Another element detected in this part of the experience is the difficulty of the students to simultaneously handle elements of very different dimensions (the sides of the yard and the linear space occupied by a person). Indeed, when we asked the children to explain their answer from their

drawings, the unanimous answer was that they had to count the drawn “dolls”. Anyway, this part of the experience was rich to detect difficulties (linked to the difference between perimeter and area) and different levels in the resolutions.

As we have already noticed, the problem was still big for the students. Once all the students had graphically described their strategy to estimate the result of the problem of the schoolyard, workgroup began. At each group, students shared their ideas they previously represented. In order to help them better understand what they had done, they were encouraged to estimate the number of students needed to surround their tables. Here we observed that some students infer the most effective way to find the perimeter of a rectangular surface from the measurement of two unequal sides: add them and then make double. Once the notion of perimeter has been introduced intuitively, the second part of the session aimed to further reduce the initial problem.

2nd part: Deduction from manipulation. To answer the question “*How many small wooden cubes do we need to surround a large wooden board?*” only 5 small cubes were provided to the children. The boards provided to each group differed in their dimensions. In some of them the solutions were whole values, while in others there was too much or too little space, in order to observe how the students faced the problem.

Some groups proposed strategies based on the cyclic movements of the group of 5 cubes in order to count the number of cubes needed to cover one side. This strategy is interesting because the idea of an effective five-in-five counting is introduced and this improves the strategy of exhaustive counting. The concept of the measurement and estimation of the perimeter of a polygon was now formally introduced to the students.

3rd and 4th session: Each group was provided with a pair of ropes of the same length (one meter) in order to solve the problem of the number of children needed to surround the schoolyard. To clearly describe the two strategies observed, we will focus on the description of the groups that we will call Group A and Group B. One of the groups was totally lost and was not able to finish this activity.

The students of Group A counted effectively (making repeated sums of four-by-four) the number of children needed to cover the four sides of the rectangle that makes up the schoolyard using their bodies as a unit. They measured two unequal sides of the yard (in which they fit 29 and 38 children), then they doubled the values and then added both values. This group of students obtained as a result that 134 children were needed to surround the schoolyard.

Group B, although they obtained the measure in “children” of one of the sides of the yard, chose to measure the uneven side using the ropes. The students measured first with the ropes, and then they were urged to find out, from that measurement, the measure in “children”. Thus, during the development of the activity, Group B students obtained a measure of “9 ropes and 3 children” for the minor side of the schoolyard. In this way, from their first measurements, the teacher asked the students to try to find out how many children fit in each string. This part is particularly interesting because two complex aspects are worked on in a simple manipulative way: the notion of linear density (*how many children complete a rope?*) and the change of units (*how to transform a measure given in big unit –rope– in a smaller one –child–?*). The students estimated that they could cover each rope with 7 children. Thus, they faced the question: “*If we know that 7 children fit in each string, how many*

*children do we have in 9 strings + 3 children?”* After discussing this problem, the students came to the conclusion that the operation to be performed was to multiply  $9 \times 7$  and then add 3. In this way, measuring the two unequal sides of the schoolyard, they infer the total of children that they needed to surround it: they estimate 292.

**5th session:** Work on scaled ground plans. During this session the students worked individually, each of them was given a scaled ground plan, a 15 cm graduated ruler and a calculator. Since they had already worked with the concept of perimeter, the first part consisted in answering the question: *“How many centimeters does the perimeter of the garden measure in the ground plan?”*

We did not identify any problem in the use of the graduated ruler (each side had a whole number measure), but we observed different strategies to obtain the total perimeter in centimeters. Some students followed the strategy of measuring each of the sides and adding the successive measurements of the sides as they got them (using the calculator). Others preferred to take note of the partial measures and, finally, add them. Once they had obtained the perimeter of the garden on the ground plan, they had to infer the real perimeter from the use of the scale (each centimeter of the plane represents 5 meters of reality). With the help of the calculator and after a whole group discussion, the students deduced that they should multiply the measurement found in the plan by 5. Next, they were asked to estimate, based on the measure of the perimeter in meters (approximately 360 meters), the number of children needed to surround the garden. Since in the previous session they had found, experimentally, that in each one-meter string 7 children can fit in, they simply had to 360 by 7. The children were very surprised by the result: they could not imagine that 2520 children were needed to surround the entire perimeter of the garden!

**6th session:** Solving the big problem. Before starting to do the calculations, the difference between a map and reality was explained again. Some students had difficulties with this concept, but we observed that those that had understood this idea were able to explain it to their classmates. Anyway, the intention of using a grid was to facilitate the use of scales, so the students were told that each side of each square of the grid corresponded to 250 people in line. Figure 2 shows a picture of the students working on the map. First, the students obtained an approximation to the perimeter of the town using the side of the square as unit. Since we told them that around 250 people fit in one square side of the grid, they just had to make one operation: multiply (using calculator) their previous result by 250. The obtained results varied between 51500 and 64500 people.

**Figure 2: Working on the gridded map**

At the end of the activity, it was important that the students could validate their solution. For this aim, we used the Google Maps tool that allows to measure distances on a plan. The perimeter of the town of Sueca measures approximately 10.5km, that is, 10500 meters. Since the students knew –from the resolution of the previous task – that 7 children fit in each meter, it was enough to multiply by 7, being the final result 73500 children. Since the number of adults that fit online in a meter is surely lower than the number of children, the result obtained by the students working on the grid was quite approximate. Therefore, the inhabitants of Sueca (around 28000 inhabitants) would not be enough to surround the perimeter of the town.

## Conclusions

The procedures associated with the measurement of magnitudes, particularly the measurement of lengths, are strongly linked to estimation processes. The choice of the appropriate unit, the use of a specific unit, the strategy of iterating a unit, more than one unit, changes of scale (moving from one unit to another), etc., are, among others, procedures associated with the act of measuring. But in addition, in real life problems, these procedures also appear when making estimations. That is why, in our current research -which begins with this work- we intend to design a sequence of tasks whose starting point is a problem of estimating large quantities that allows us to introduce, at an early age, procedures linked to the length measurement.

We have presented here the design of a sequence of tasks that starts from a Fermi problem that is unapproachable for students. Thus, from two elementary heuristics of Pólya's work, a sequence of tasks is constructed. The sequence begins with the simplification (named downscaling in our context) of a large problem. In this way, when students are able to develop a procedure in a reduced context, we encourage them to generalize (upscaling process, in our context) that procedure to apply it in a larger context. We have implemented the sequence with a natural group of 21 second grade students. A first qualitative analysis of this intervention allows us to identify some aspects of interest to work on in the future. The following are the most interesting ones. At the start of the sequence, in the second session, we have detected that the children have difficulties in differentiating the reality from the representations of the real world. Thus, they try to find out the number of children that fit on the perimeter of the track by simply counting the children (or their abstract representations) in their own drawings. This reminds us of the importance of introducing, even in a very simplified way, the idea of scale. We have also observed some difficulties in the process of using physical elements as units of measure. This is why we think that our proposal, and the future versions we'll make of it, has to foster students to make use of different units (cubes, children, ropes and, finally, graduated rules). In this sense, we have observed that, in the third and fourth session, a group of students was totally lost. The problem was not, apparently, the mathematical activity itself, but the fact that they were not used to work outside the classroom. This is an aspect that should be considered in our future work.

The proposed sequence has also allowed us to observe the evolution of the students. Given that this is not an isolated activity but a sequence, some of the students had the opportunity, in the next activity, to assimilate or discover the procedures they were working on. In addition, they were able to put them into practice in another context. This seems to us a strong point of our sequence, but we will have to test its efficiency by working with more students.

Furthermore, the sequence design aims to support the teacher's task that, in many cases, feels overwhelmed to bring this type of activity to the classroom. In this way, its own design serves the teacher as a guide to be able to offer what Stender and Kaiser (2017) call strategic interventions. Finally, we want to highlight that the designed activity allows working the validation phase that, from our perspective, is fundamental when solving any problem of real context.

# Students of Development Studies learning about modelling and simulations as a research approach in their discipline

Amrit B. Poudel<sup>1</sup>, Pauline Vos<sup>1</sup> and F. LeRon Shults<sup>1</sup>

<sup>1</sup>University of Agder, Norway; [amrit.poudel@uia.no](mailto:amrit.poudel@uia.no); [pauline.vos@uia.no](mailto:pauline.vos@uia.no); [leron.shults@uia.no](mailto:leron.shults@uia.no)

*Researchers in the social sciences are increasingly using modelling and simulation (M&S) as a research approach. They create virtual worlds to discover relations across variables, and to test theories and potential policies. We introduced this research approach to students in the department of Development Studies at our university. The goal was to investigate the way in which such students can gain meta-knowledge about M&S-based research, that is, general knowledge about its nature and rationale. We organized a seminar to introduce the research approach and illustrated it with a simulation of the behaviour of agents with varying levels of tolerance towards their out-group neighbours (based on Schelling's segregation model). We analysed students' interactions through a socio-cultural lens. Students were able to gain meta-knowledge about M&S-based research, which they judged as useful for their future as professionals when working on development projects.*

*Keywords: Development studies, mathematical modelling, meta-knowledge, Schelling's segregation model, simulation-based research.*

## Introduction

A growing number of universities are running programs in *Development Studies*, a relatively new, interdisciplinary field building on economic and social sciences. This discipline focuses on issues regarding regional, national, and global development, such as food security, health, energy, and migration. Graduates from Development Studies departments often find placement in organizations whose agendas relate to social responsibility, sustainability and economic development (e.g., UNESCO, FAO). Research published in the *Journal of Development Studies* utilizes both quantitative and qualitative methods to shed light on both macro and micro variables that impact economic and social development, typically focusing on less affluent regions. Increasingly, researchers in Development Studies use mathematical models to simulate complex social and economic systems. For example, Kumar and Venkatachalam (2018) used survey data from bank loan applicants of various castes in rural India to create a model that enabled them to run simulations of different hypothetical scenarios; they found that lower loans were given to farmers from lower castes but, surprisingly, this discrimination did not affect owners of small farms. This research approach, in which modelling and simulation (M&S) is utilized, typically involves the following steps. Researchers begin with a real-world problem revealed by statistical, ethnographic or other analysis. Often, these problems are of particular interest to politicians and others attempting to improve the conditions for those in less affluent contexts. Researchers then identify relevant variables and construct a *causal architecture* that reflects both insights from theoretical literature and findings from empirical data. This work results in a mathematical or computational model. Using software such as NetLogo, they then simulate in the virtual world the phenomena observed in the real world. In this way, the real world data help to validate the model. However, the main goal

of M&S-based research approaches is not to create models, but to answer ‘*what if?*’ questions by varying parameters in the model. Researchers can create a variety of scenarios and run a large number of simulations, often visualized in graphs, in order to discover complex interactions in the relevant socio-economic systems and, in some cases, to ‘predict’ the future behavior of those systems under certain conditions.

The steps in a M&S-based research approach can be illustrated by the modelling cycle in Figure 1, which is an adaptation from Greefrath, Hertleif, and Siller (2018), and based on earlier work by Blum (2015) and Kaiser (2014). Researchers start by investigating real world data and potential causalities to build a mathematical model, after which they run simulations to control whether the model aligns with the real data. They will iteratively improve the computational model until it fits the data, thereby repeatedly ‘going through’ the modelling cycle. In a subsequent phase, they ask ‘what-if’ questions and experiment, based on givens in the real-world (e.g., possible policy measures). By varying parameters in the model, and running new simulations, they obtain mathematical results that they translate into real results. After publishing, their results may be implemented and, possibly, solve real world development issues.

**Figure 1: The modelling cycle, with visualizing and simulating digitally**

Curricula of Development Studies differ across universities. According to Djohari (2011) and Engel and Simpson Reeves (2018), curricula emphasize the teaching of academic theories (e.g. social justice theories), critical and anti-colonial thinking, or skills useful for future development workers (e.g. project management). Most universities offering Development Studies include a course on research methods, typically focusing on qualitative methods. Only a few require statistics, since quantitative methods are known to be a hurdle for many social sciences students (Onwuegbuzie, 2004; Zeidner, 1991). At this point, curricula in Development Studies rarely incorporate the newer M&S-based research approaches, although these are increasingly used in this discipline. This lacuna in the curricula challenged us. We hypothesized that any Bachelor or Master’s student could understand generally how social simulations can assist academic researchers in their research. In other words, they can gain a *meta-knowledge* of M&S-based research, that is, general knowledge about the nature of such research, its rationale, the way it is conducted, and the extent to which it can provide policy-relevant information. For our definition of meta-knowledge, we borrow from Brown and Stillman (2017), who also used the term meta-knowledge in relation to modelling. To explore our hypothesis, we organized a voluntary seminar aimed at giving students a ‘feel’ for the

explanatory power of simulations, so they could gain meta-knowledge about the research approach without a technical introduction to the simulation software, the computer codes, etc.

## Theoretical frame

We based our analysis of students' interactions in the seminar on Cultural-Historical Activity Theory (CHAT) (Engeström, 1987). This theory focuses on the way in which, for example, the learning environment and students' social backgrounds interact with what students think and how they communicate. Within mathematics education, CHAT has proved useful in various studies; e.g., in research on how college students negotiate a workplace's and school mathematics' worlds (Wake, 2014). Following CHAT, the students in our seminar are understood as *actors* participating in different *worlds*. In the first place, they are participants in a learning context (in a Development Studies program, attending lectures, pursuing a degree). Second, they are oriented toward becoming professionals within a development organization (e.g. an urban planner in a less affluent country). Third, they might have the ambition to become member of a research community (within a university, publishing academic articles). Fourth, they are citizens in the real world (as consumers, migrants, etc.). Each of these worlds has its own conventions, norms, jargon, tools, etc.

When connecting the above CHAT-based *worlds* to insights from research on mathematical modelling education, we observe that in the modelling cycles of Blum (2015) and Greefrath et al. (2018), there are two worlds: the real world and the mathematical world. These are two *worlds* that both an M&S-researcher and a student in a mathematical modelling classroom *negotiate*. As Doerr et al. (2017) pointed out, describing modelling activities in terms of real and mathematical world is challenging. For example, the real world is far larger than the context of a modelling problem. Students and researchers participate in this larger world, and they may or may not have experiences with the problems addressed in M&S-research or in the classroom. Employees within development organizations also participate within this larger real world, but professionally they focus on a narrower world of specific problems in less affluent contexts. Researchers using M&S-based approaches operate primarily within the mathematical world of Figure 1; their work consists of identifying variables, creating relations between these, creating computer codes, running thousands of simulations, creating numerous graphs, and writing technical academic articles. So, although they work typically for the sake of the real world (global, national and regional development issues), the world of M&S-based research is mainly a mathematical world. The distinction between real world and mathematical world as depicted in Figure 1 has emerged from research into mathematical modelling in classroom contexts. However, this differs in several ways from the modelling activities of professional researchers. Students in classrooms often only 'go through' the modelling cycle once rather than several times, they use existing models rather than create new ones, they work with descriptive models rather than explanatory ones, they use educational digital tools if any (e.g., Geogebra) rather than professional computational programs, and their errors are less likely to have social and political implications (Doerr et al., 2017; Vos, 2018). In our study, we didn't ask students to engage in modelling activities, but rather to learn about the work of researchers utilizing M&S-based approaches. Therefore, we were not expecting to observe them operating in a mathematical world.

Our overarching research question was: to what extent can students in a Development Studies program gain meta-knowledge about the relevance of M&S for their discipline during a short intervention seminar? We had several sub-questions: to what extent can this interactive process enable these students 1) to understand the way in which these research approaches describe and explain social dynamics, 2) to grasp the basic benefits and limitations of M&S-based research, 3) to gain a sense of how researchers in Development Studies use such research approaches, and 4) to imagine themselves as future researchers using M&S-based approaches?

## Methods

We used a design-based research approach for this project. This involved designing a seminar, implementing it, evaluating it, and then planning to repeat iteratively the intervention. Design-based research aims to improve educational practice in cases where new content is taught (Plomp & Nieveen, 2013). The study reported here was the first of its kind; in forthcoming iterations, we intend to have improved seminars on the same topic with another group of students. In this study, the participants were three Nepali students from a master's program in Development Studies: we refer to them as Student B (female), Student K (female), and Student S (male). The first author of this paper was the leader of the seminar, which was conducted in Nepalese. The seminar was designed to last 3 hours and consisted of three sections. The first section introduced some relevant social problems (e.g., the 2015 earthquake and its social consequences, segregation and violence) and the impossibility of using experiments to study this sort of phenomena (i.e., exposing participants to exclusion or violence is unethical), and a first introduction to M&S-based research approaches. The second section involved a semi-guided activity, described in more detail below. The third section consisted of a discussion triggered by probing questions by the seminar leader. To illustrate the research approach, we included a hands-on simulation experience regarding an issue relevant for Development Studies: the migration and segregation of a city's inhabitants. In this part of the seminar we used an educational applet, which offers a simulation of the well-known Schelling Segregation model from Nobel Prize laureate Th. Schelling (Schelling, 1971). This applet, available from <http://nifty.stanford.edu/2014/mccown-schelling-model-segregation>, see Figure 2, begins with a random distribution of a population with two groups of *agents* (indicated by red and blue blocks). Depending on an agent's wish to live with same-colour neighbours (in other words: its tolerance for living with neighbours from the out-group), it will move to a new location. In Figure 2 the slider for similarity tolerance is set to 54%, which means that an agent is 'satisfied' when at least 54% of its neighbours share its colour. If the number of same-coloured neighbours falls below this threshold, an agent moves to an empty spot (a white block). The simulation famously shows that even with a relatively high level of tolerance at agent-level, clustering quickly begins and segregation takes over in the city.

Students' interactions were video recorded and transcribed. We analysed these in light of the theoretical frame by going through the transcripts and identifying utterances, in which the students positioned themselves in a *world* (for example, by their use of the term 'we' or by their description of experiences). We coded when the students engaged (1) as participants in a learning environment, (2) as future development professionals, (3) as potential M&S-researchers in Development Studies, or (4) as citizens in a dynamic society. The analysis resulted in clear, and sometimes multiple codes.

**Figure 2: The Schelling Applet, at the start (left), and after 26 simulation rounds (right)**

## Results

The first part of the seminar was basically a lecture, which we didn't code due to the absence of students' utterances. The second part was a semi-guided activity with the Schelling Applet. The students sat together at one laptop, and interactively ran simulations to see the effects of varying the tolerance parameter. They tried many scenarios, and consistently found that raising agents' bias leads quickly to segregation, and that even relatively low levels achieved the same result, albeit more slowly. They also tried removing the empty spaces and discovered that no segregation could occur since "*no options are available anymore*" (Student S). They had experienced that in times of crises, people need to be tolerant: in the case of the Nepalese earthquake, people moved in with each other or lived peacefully in overcrowded tents. Student S was critical of the applet, commenting that in real life the space of a city is not restricted, and people would move beyond the city borders to build bigger houses. Student B mentioned that she knew of an influential person who moved to another place after the earthquake, after which his whole clan soon followed; in this case, the clustering tendency was already present before the segregation. In terms of the CHAT framework, the students were primarily participants in a learning environment (discovering the effects of changing sliders in the applet), but also expressed their real-world experiences as citizens. During this second part of the seminar, we observed the students speak neither as future professionals nor as researchers. The third part of the seminar was a discussion guided by probing questions, the first of which was: "what questions from Development Studies could be answered by studying virtual worlds?" Student S suggested that the different clusters of people could be studied with respect to their socio-economic status. The seminar leader realized that such a study would likely require a survey, rather than a simulation, but did not comment so the others could respond. Student B then said that simulations provide a dynamic visualization of phenomena and enable researchers to observe long-term changes visually. She suggested that simulations could be a medium for communication "*for those who hate large data sets*" and do not have a strong background in mathematics. At this stage, the students were participating as potential future Development Studies researchers, in a world in which they anticipated executing and publishing quantitative research.

To focus on their future professions, the seminar leader asked the students to think as *urban planners*; how might the latter make use of simulations? This triggered a lively discussion on how urban planners could promote a tolerant community. The students agreed that the Schelling Applet represented a certain underlying structure in society, although agents' movement in the real world is related not only to the colour of their neighbours but also to other factors, such as economic concerns, or a desire to live close to relatives. They then discussed ways in which a simulation of road networks could show how certain groups have better facilities (e.g., close to hospitals, accessible to firefighters), and how M&S-research could contribute to improve urban lives:

Student B: We can find out the road conditions, specifically in Kathmandu. Because they are constructing roads in different places. I want to know whether it [the road network] is effective or not, basically, already at the planning stage.

Leader: How effective is that planning? Any examples?

Student B: For example, roads in Kristiansand [Norway] are well planned. If you walk in this city, nobody gets lost. But in Kathmandu, we always get lost or run into a wall [dead-end]. With these [simulations], we can study the trend of urbanizations. We can compare the situations. Find out the areas where more housing is needed.

Student B was imagining ways in which a simulation could help her understand and predict dynamics of urban life. This triggered the other students to identify additional scenarios, in which simulations could be used. Here, the students were thinking of themselves as potential researchers who might use M&S methods for urban planning. In addition to seeing themselves as citizens (travellers, migrants, etc.), they also perceived themselves as future professionals contributing to developing their communities through simulations to analyse and predict social dynamics.

Student B: Here is a different thought... If I have a virtual Nepal, I think we can find vulnerable places for a natural disaster. We can find out how likely it is.

Student K: If we talk about health facilities, there is one health post in a VDC [Village Development Committee; Nepalese term for a rural organization unit]. Isn't that right? Any VDC has 9 wards and the health post will be in one ward. For [people in] other wards, it is far. So, if we can see distance virtually, then it will help us to decide whether there is a need for an additional health post.

Student B: For example, in the Artificial Intelligence Systems course, we studied the PredPol model [an Artificial Intelligence system used by the police in Los Angeles]. If we borrowed the PredPol model, which will be helpful to identify key places where crime is increasing. It will be helpful to estimate sufficient armed forces for those identified places. Find out the crime spots observing past situations. This PredPol model is helpful to predict future crime using previous data.

Student K: A predictive tool

Leader: (...) Is that model a simulation?

Student B: I think it is a simulation model, because it helps us to predict.

We see here that the students used “we,” speaking as future policy makers who assist their societies prepare for natural disasters, set up health posts, or fight criminality. At the same time, they speak as researchers, using verbs such as “find.” When asked to identify the limitations of M&S-based research, Student S pointed out that simulations do not produce realistic pictures, Student B wondered whether M&S methods were sufficiently scientific, and Student K asked about the expense and training required for creating models. However, Student B noted that a simulation’s visualizations could be helpful for communicating with less-educated people. All three agreed that simulations can serve as a tool for prediction in guiding critical decisions, as well as facilitating understanding of the social dynamics of urban life, enabling governments to develop better policies. The students grasped that development professionals might implement the recommendations of M&S-based researchers even if they did not use the tools themselves. Finally, when asked if they could imagine themselves doing M&S-based research, Students K and S were silent, but Student B said *“your presentation made clearer what a model is. Before coming here, I didn’t know what a model is. I am interested.”*

## **Conclusion, discussion and recommendations**

We observed that the students were largely able to understand the opportunities and challenges of studying social dynamics through M&S-based approaches, connecting it to prior knowledge of artificial intelligence systems that simulate future scenarios. They described possibilities for using simulations for planning roads or identifying places vulnerable to natural disaster or crime spots. Mostly, they expressed themselves as future professionals in development projects who would use results from M&S-based research. In the process, they shifted roles from learners, to citizens, and future development professionals, but not to researchers at a university using M&S-based approaches. Thus, the seminar assisted them in gaining meta-knowledge about the relevance of M&S for development professionals, but to a lesser extent for researchers in their discipline. The students understood that the Schelling Applet was an example of a simulation, which simplified real life processes, but that despite its limitations the simulation had explanatory power for certain social dynamics. Thus, the applet served as an educational tool helping students to transcend the learning environment into other worlds and to imagine what other simulations could look like when used by development professionals. However, students’ erratic interchanging of terms like ‘model’ and ‘simulation’ showed that they had only a cursory sense of M&S-based approaches. Their capacity to gain meta-knowledge was restricted by their lack of experience in creating models and running simulations. Since we didn’t ask students to engage in modelling activities, we kept them away from the mathematical world. So, they learned about M&S, but not the advanced aspects of the real work done by M&S-based researchers (identifying variables, creating relations, coding, etc.). How best to introduce novices to creating simulations remains an open question.

In a future iteration of the seminar we could put more emphasis on how and why researchers in Development Studies increasingly embrace M&S. Inspired by a comment from one student, we might also show how M&S provide a powerful tool for communication. Further, we could stress the way in which M&S-based approaches can capture link the micro- and macro-level (e.g., tolerance between individuals and the segregation of a city), as well as their relevance for their future as professionals studying issues such as urban planning, disaster preparation, or crime prediction.

CHAT provided a productive framework for understanding the way in which students engaged in the seminar as participants in different worlds. This study revealed that a seminar was sufficient for promoting meta-knowledge about the nature and relevance of M&S in Development Studies but highlighted the additional competencies that will be required if they pursue these approaches as professionals. These findings will help us improve future seminar iterations with other students.

# On the role of multicriteria decision support in mathematical modelling

Stefan Ruzika<sup>1</sup> and Lisa Schneider<sup>2</sup>

<sup>1,2</sup> University of Kaiserslautern, Department of Mathematics, Germany

[ruzika@mathematik.uni-kl.de](mailto:ruzika@mathematik.uni-kl.de); [lisa.schneider@mathematik.uni-kl.de](mailto:lisa.schneider@mathematik.uni-kl.de)

*Modelling is one of the key skills in applied mathematics. This is reflected by the Standing Conference of the Ministers of Education in Germany, and, consequently, mathematical modelling is one of six competences mentioned in the Educational Standards. There is a vast amount of literature representing, discussing, and teaching modelling. In practice, a mathematical model serves the purpose of making fast, cheap and – probably most importantly – reliable decisions. Having this in mind, one should reconsider the way mathematical models are treated in activities with students. In this paper, we advocate a ‘multicriteria’ perspective on mathematical modelling, optimization and decision making. We present several examples from real-world problems illustrating the need of multicriteria decision making and give some first hints toward incorporating this multicriteria perspective in the well-known mathematical modelling paradigms.*

*Keywords: Mathematical models, decision making, multicriteria optimization, STEM education.*

## Introduction

Mathematical modelling is considered to be an important topic in our daily life. The usage of mathematical models is often not apparent, but they are omnipresent. Moreover, modelling and applications have been an important topic in mathematics education with growing importance since the late 1990s (Blum, 1993; Blum & Borromeo Ferri, 2009). Showing the applicability of mathematical ideas to real-world problems increases the motivation of students to study mathematics as well as their knowledge of several mathematical concepts (Borromeo Ferri, 2009). Furthermore, modelling provides opportunities to integrate mathematics in the curriculum that allow multidisciplinary teaching. Therefore, the need and the benefits of teaching mathematical modelling competences at school have already been recognized several years ago (Blum, 1993; Blum & Borromeo Ferri, 2009). Students should be able to set-up, simplify, analyse and compare mathematical models (KMK, 2012). The mathematical modelling competences of students should be stimulated with regard to other mathematical and general competences: the ability of communicating and discussing mathematical problems as well as designing and applying problem solving strategies. Moreover, the methodological, social and personal competences are increased (KMK, 2012). Obviously, mathematical modelling becomes a more and more important skill for students.

## A general view of mathematical modelling

### Mathematical models and modelling

Having stressed the necessity of mathematical models and modelling, we now review these concepts briefly. Though the notions of ‘modelling’ and ‘mathematical model’ show overlaps, differences are observable: Modelling means to construct a mathematical model, so we first discuss the mathematical modelling process before we consider modelling cycles. There is a broad consensus in the

international discussion, that mathematical modelling is a process which translates between reality and mathematics in both directions (Blum & Niss, 1991). Pollak (1979, p. 233) defines mathematical modelling as a special aspect of applied mathematics. He distinguishes between several definitions: The “classical applied mathematics” and the applied mathematics with focus on a “significant practical application” are part of the mathematics as a whole. Furthermore, applied mathematics implies going around the cycle once: “Beginning with a situation [...] in real life, making a mathematical [...] model, doing mathematical work within that model, and applying the results to the origin situation”. Another definition of applied mathematics refers to the preceding definition, but means going around the cycle more than once. The last two definitions are process-oriented and focus on the real world. This implies that modelling is a process for solving real-life problems. Borromeo Ferri and Blum (2009, p. 45) define a mathematical model as “the process of translating between the real world and mathematics in both directions”. Reit (2016) states, in the tradition of Pollak (1979), that mathematical modelling is not a process in both directions: The translation from reality to mathematics is a mathematical model, the reversal, the process from mathematics to reality, is an application. Thus, modelling emphasizes the process – the implementation of real problems in mathematics – while applications focus on the mathematics. The aim of a mathematical model is, as already stated by Blum (1993), the comprehensible simplification of the real problem for enabling the application of mathematical methods. Just a few details from reality are considered. The fundamental properties will be extracted and translated into mathematics; the simplification of the problem usually results in a solution. These models are not unique and non-linear processes; there often exist several mathematical models for a real-life situation (Greefrath et al., 2013). For Blum (1993, p. 4), the mathematical modelling begins with a situation in the real world. The problem has to be structured and simplified, so the solver gets “a real model of the situation”. Then, the real model will be translated into mathematics. The result is a mathematical model. In the next step, the model is solved and translated back into the real model. Often, the first model-based attempt to solving a problem is not satisfying. Thus, more attempts might be necessary which is why mathematical modelling should be regarded as a cyclic task.

### **The concept of modelling cycles**

As Blum (1993) illustrated, the process of mathematical modelling is often depicted in terms of modelling cycles – a representation which is widely accepted. Modelling cycles are useful to describe a mathematical process. A huge number of such cyclic representations are discussed in the literature: They mainly differ in the concept of the sub-steps, the number of sub-steps or the chronological order of the sub-steps. We are geared to the categorization due to Borromeo Ferri and Kaiser (2008), which characterizes the modelling cycles by their phases: The easiest example of a cycle has a real-life problem at the beginning. This problem leads to a real model, which has to be translated into a mathematical model. This model is treated mathematically, and the result is transferred to the real-life problem. Greefrath et al. (2013) define three categories of modelling cycles with the focus on mathematisation: the direct, the two-step and the three-step mathematisation. For the directed mathematisation, it is typical that there exists only one step from the real-life problem to the mathematical model. The direct transition between real-life problem and mathematical model refers to the definition of applied mathematics. In contrast to the directed modelling, the modelling cycles

in the two-step mathematisation include an additional step between the real-life situation and the mathematical model. The most famous modelling cycle of this category is from Blum (1985). The simplification of reality is called the real model and is a phase of its own. This kind of modelling cycle is typically used for modelling in school. The three-step mathematisation is characterized by the cognitive process. In modelling cycles, this cognitive process is described by an own phase: the situation model, i.e. the mental representation of the situation (Borromeo Ferri, 2006). For Blum and Leiss (2007) the phase of the situation model is the most important one during the modelling process. This phase characterizes the translation between the real situation and the situation model, so it can be seen “as a phase of understanding the task” (Borromeo Ferri, 2006, p. 87).

### **Research question**

Literature on mathematical modelling, especially on modelling cycles, has not focused much on aspects of discussing of a solution provided by using a mathematical model. Multicriteria decision making as an element of mathematical modelling has not been addressed at all to the best of our knowledge. Our proposal is to take multiple criteria and perspectives into account and to research how the multicriteria perspective can be incorporated in mathematical modelling. In this paper we examine how decision making affects mathematical modelling in schools and extracurricular activities with students by elaborate and discuss two example cases (see below).

### **Multicriteria decision making (MCDM)**

Decisions are an important part of our life, they consider multiple, often contradicting criteria. Thus, solving decision problems is difficult: The simultaneous consideration of different alternatives and their consequences often prevents us from making a good decision. We all strive for a “good” decision and frequently “solve” MCDM problems. From a mathematical point of view, trading-off between contradicting criteria needs the integration of multicriteria optimization and decision-making methods into modelling cycle.

### **Mathematical background**

One of the main characteristics of multicriteria decision making is the presence of several, non-commensurable objectives to be pursued by an entity (e.g. a person, a group or a company) called Decision Maker (DM). It is generally assumed that a DM tries to maximize his/her utility while choosing one out of a set of alternatives. Utility is a theoretical concept which describes the value of some alternative for the DM; however, it is assumed that the DM is not able to describe ‘utility’ in a closed-form function. Instead, a DM may only be able to provide partial information about specific preferences or tendencies. Depending on how much information is provided by a DM before or during the establishment of a mathematical model, one can distinguish three basic approaches in multicriteria decision making: ‘a priori’, ‘interactive’ and ‘a posteriori’ approaches (T’Kindt & Billaut, 2002).

In ‘a priori’ approaches, the DM is able to express preferences before a model is built. These preferences are taken into account during a process e.g. as parameters, as weights or as ordering relations. The result is a model which reflects the DM’s utility as well as possible, and the set of ‘reasonable’ alternatives delivered by the model or the decision support is consistent with the DM’s preference information.

In ‘interactive’ methods, the DM takes part in the modelling process by providing some initial, yet vague information about preferences. A first rough model is built and treated mathematically, thus showing consequences and possibilities of different alternatives to the DM. Based on this information, the DM is able to specify preferences more precisely, since he/she is now more educated. The model is refined, the consequences are shown to the DM who then refines the information provided and so on. This process is iteratively repeated until a satisfactory model is set up. It is then treated in detail and, as a result, a set of reasonable alternatives is presented to the DM, among which a final preference has to be chosen when making a decision.

In ‘a posteriori’ approaches, it is assumed that the DM is not able to specify any kind of preference information beforehand. This may be due to the complexity of the real-world problem and the fact that certain meta-information or expert knowledge which may be important in decision making can often not be captured by a mathematical model. Moreover, a DM often makes decisions based on ‘experience’ or ‘depending on the specific case’ and, again, these issues are hard or even impossible to model. Under such circumstances, a mathematical model and the mathematical methods for dealing with such model (i.e., simulating, optimizing, etc.) often rely on the concept of Pareto dominance: an alternative is preferred to another, if it is at least as good in any of the objectives.

### **Multicriteria decision making and mathematical modelling**

Methods for solving decision problems are helpful to support students within the modelling process, especially they motivate to remodel the mathematical model. In this section, we point out the relation of the three basic approaches in multicriteria decision making to perspectives on mathematical modelling. In the ‘a priori’ approach, the simplifications are done in the real model from the DM, before a mathematical model is developed. The preferences made by the DM are implemented in the mathematical model in terms of parameters, weights, etc. The set of alternatives which are found in the mathematical model, correspond to the DM’s preference information. No further loop in the modelling cycle is needed. In the ‘interactive’ approach, the real model has to be formulated and then translated into the mathematical model. The DM can specify preferences based on the results of the mathematical model, since he/she has more information. The real model will be adapted and a suitable mathematical model is (iteratively) solved. More attempts might be necessary to find a final preference for making a decision. In the ‘a posteriori’ approach the DM does not specify any preference before the modelling process. Therefore, the real model is set up and then translated into a mathematical model. After solving the mathematical model, a set of alternatives can be presented after the modelling process. The DM can choose the alternative which fits best to his/her most important criteria. Because of the complexity of the problem and the huge set of alternatives, the DM might need additional support in choosing the finally preferred solution.

### **Cases and experiences**

In the following subchapters, we report about several cases in which we extended mathematical modelling perspectives by aspects of multicriteria decision making.

### **Case 1: *Stiftung Warentest* – Analysis of product tests**

*Stiftung Warentest* investigates and compares objects with multiple, often contradicting criteria such as functionality, price or usefulness. It supports consumers in making their decision between alternative products. Ratings are issued and supplemented by rankings. Thus, these rankings are used for a first orientation and support the decision-making. Products are usually tested in a certain way: There are multiple categories, i.e. criteria, which are important for the rating of the product. In a further step, several methods for the product rating will be developed. Next, the products will be tested, and the results will be evaluated. The method for establishing a ranking can be implemented in school, since it uses various techniques dealing with topics in the range of analytic geometry and linear algebra (points, planes, distances) and stochastic (mean, variances). The central content of the teaching unit is to develop a method for ranking objects with the means of the multicriteria optimization (Ruzika, Klöckner, & Gecks, 2018). This teaching unit was situated within a classroom context in three units of 90 minutes. The execution of the teaching unit was conducted in a 12th grade class with 17 students at a *Gymnasium*. The teaching unit is opened by demonstrating examples of rankings from several areas, e.g. electronics or restaurants. The students are motivated to discuss about attributes of rankings and point out the difficulties of such rankings. It is obvious that the multiple criteria which influence the rating are contradicting, for instance price versus quality. Then, the students investigate how the multiple, contradicting criteria are treated by a weighted sum aggregation and how this method of establishing a ranking of products can be analysed geometrically. Students work out how the rating is compounded and how the best product can be determined. To simplify the problem, the number of categories of the ranking will be reduced, so that the students can develop how the test of a product can be implemented in mathematics. Using the weighted average of the rating in each objective, the ranking can be established and analysed with the help of a coordinate system. This leads to the observation that several products can make the top of the list depending on the chosen weights. More surprisingly, it can be observed that under some circumstances, ‘reasonable’ products which a customer would intuitively prefer, are not rated best in any scenario. But what if the test includes more than two categories? In a next step, the students have to revise and extend their mathematical model, which considers now more categories. With the help of a spreadsheet, they simulate the influence on the ranking, while different weights for each of the categories are chosen. Just as in the mathematical model with two categories, the application of different weights causes different rankings. After this teaching unit, it can be investigated how a ranking can be done in a fair and consumer-friendly way. The goal will be to find a product which is robust in a certain sense.

### **Case 2: *Navigation for electrical vehicles***

Decision making in the context of finding routes for electrical vehicles requires the consideration of multiple, often conflicting criteria. Thus, the selection of a route involves the consideration of several aspects: The battery consumption should be as small as possible while simultaneously the travel time should be as short as possible. The determination of efficient and optimal routes can be based on analytic geometry. In an extracurricular activity, we have worked on this problem for three days with a group of girls aged 16 to 18. The course was opened to introduce the students into the basic problem: Finding optimal routes for electrical vehicles. In a first step, the students simplified the problem and

focused for the beginning on one criterion only – the shortest path for a route. For solving such a problem, they obtained a theoretical input in form of a short teaching unit about network optimization containing the basics about (directed) graphs and Dijkstra's algorithm. In order to achieve a motivating connection to the real world, students applied their knowledge about finding a shortest route on a selected example themselves. The goal was to find optimal routes for electrical vehicles, so students were motivated to discuss about several criteria which should be considered: price, energy consumption, speed, location of charge stations and travel time. After observing that, for an electric vehicle, energy consumption is increased by driving with higher speed and, that energy consumption is directly connected to the cruising range, the students realized that one important problem is the selection of a route that satisfies both criteria – consumption and distance. But how to compare routes with two objective functions? Next, students received a little more input – this time in multicriteria optimization. They learned about methods for the computation of efficient routes. With the knowledge of these methods, they extended their mathematical model from the beginning. The students chose two solving strategies: One group focused on the implementation, e.g. with GeoGebra. They plot the objective values for the different routes for the criteria travel time and energy consumption. The students recognized that efficient routes can be determined by considering the dominance cones of each route and that an efficient route is never contained in the dominance cone of another route. The second group implemented a multicriteria Dijkstra variant, e.g. using Python, in order to find an efficient route. In conclusion, the students compared their methods: The implementation in GeoGebra is descriptive but has the disadvantage that this method can only be used for given routes. This is the advantage of the implementation in Python: This method can be used for arbitrary areas and routes; the graph of the road network can be imported.

## Conclusion

The cases *Stiftung Warentest* and *Navigation for Electrical Vehicles* follow the 'a posteriori' approach. In the teaching unit *Stiftung Warentest*, students discuss attributes of a ranking. They point out that it is very difficult to express preferences about the most important criteria. Thus, in a first step, they simplify the problem because of its complexity. After solving the mathematical model, which is based on the weighted-sum method, they observe that one alternative is preferred to another. In a further step, they extend the mathematical model and include more than two criteria. Based on a method from multicriteria optimization, they reach a solution which is at least good for one of the criteria. It is obvious that the students remark any preference for the criteria before they build the mathematical model. In the extracurricular activity *Navigation for Electrical Vehicles*, the students are not able to make a 'good' decision for finding an optimal route, since several aims are contradicted. Because of the complexity of the problem, they cannot weigh a criterium more than another. Thus, they simplify the problem in a first step and solve it for one criterium. It is very hard to establish a mathematical model based on their experiences and their meta-information. Thus, they apply methods from the multicriteria optimization to solve the mathematical problem, e.g. solving the real-life problem. Students are not able to express preferences before they establish the model. Hence, the usage of the Pareto concept of dominance helps modelling and solving the problem.

The input about multicriteria optimization, especially about methods for solving decision problems, support the students in their modelling process. The usage of multicriteria optimization methods

supports the establishment of the mathematical model and the extended remodelling of the real model. Furthermore, they obtain an overview on how the process of multicriteria decision making is staged. They learn how to handle multiple, contradicting criteria and find a trade-off between them. We support their modelling process with input for several reasons: Using the ‘a priori’ approach, preferences are taken into the model, e.g. criteria are weighted. The result is a model which reflects the student’s, i.e., DM’s utility. In contrast, in the ‘a posteriori’ approach, no criteria are weighted before the modelling, and several alternatives can be presented after the modelling process. Thus, the DM can choose the alternative which mostly reflects their most important criteria. With regard to the competences, it is apparent that, apart from the modelling competence, other competences are promoted and extended as well: They use mathematical tools, such as GeoGebra and Python, to solve problems, they communicate mathematically using terms like ‘efficient’ or ‘dominating’, and they apply solving problem strategies.

We have seen that methods of the multicriteria optimization can be didactically reduced for students. The focus on the most important aspects and their proper visualisation lead to an adequate implementation in a school context. Both examples show a contribution to authenticity – real world problems reinforce the students’ motivation obviously. Students get to engage in critical thinking: They can ask provocative questions and concentrate on finding their answers. Based on the answers well-founded decisions are made. By giving them additional input, we enable the students to work with these methods on their mathematical model. We call this process modelling: We influence the modelling process in a way, but – what is more important in this case – we support the establishing of a mathematical model, so that students are supported to make decisions and solve problems with multiple, contradicting aims. The students go through the modelling cycle more than once: They simplify the real-life situation to a real model, establish a mathematical model, improve the real model, extend the mathematical model and solve this with the help of given methods. These results are applied to the origin problem. The emphasis lies on the “last node” of the modelling cycle: the application of the mathematical results to the real world problem. After the modelling process the used mathematics are discussed, reflected and justified. In conclusion, these two cases show how the multiple perspective can be incorporated in mathematical modelling. We have shown that decision making affects the mathematical modelling in a school context and also an extracurricular activity. Our aim is to evaluate the benefits and the drawbacks of this approach rigorously in future research.

# Exploring pre-service teachers' flexibility in solving Fermi problems

Carlos Segura<sup>1</sup> and Irene Ferrando<sup>2</sup>

<sup>1,2</sup> Universitat de València, Spain; carlos.segura@uv.es; irene.ferrando@uv.es

*Keywords: Flexibility, estimation, modelling, problem solving, pre-service teacher training.*

## Theoretical framework and purposes

Realistic Fermi problems are open problems, connected to the real world, which require students to make assumptions about the situation of the problem and estimates about the relevant quantities, and whose solution is accessible to all students, admitting different levels of complexity (Ärleback, 2009). Students do not immediately have known procedures to solve this type of problems, so their solutions include a variety of strategies (Albarracín & Gorgorió, 2014). This exploratory work is a part of a research started two years ago focused on studying problem-solving process of Fermi problems based on obtaining an approximation to the number of elements in a bounded enclosure. In Ferrando et al. (2017) the solution processes of this class of problems have been analyzed (following Lesh & Harel, 2003) using a mathematical model characterization that includes a conceptual system for describing the relevant mathematical objects and their relations, and accompanying procedures for generating useful constructions, manipulations or predictions. This work has allowed us to identify three types of solution strategies for this class of Fermi problems: (i) based on the notion of population density; (ii) based on the use of a base unit; (iii) based on the use of a geometrical pattern (Ferrando et al., 2017, p. 229).

Star and Rittle-Johnson (2008) define flexibility in problem solving as knowledge of (a) multiple strategies and (b) the relative efficiency of these strategies. According to CCSSI (2010) flexibility in problem solving is related with mathematical competence. Nevertheless, teachers have still some difficulties to develop flexible reasoning when solving mathematical tasks. This leads us to consider whether pre-service primary school teachers know and use different strategies to solve Fermi problems. In particular, this study will address the following research questions:

Q1) According to the different strategies identified in a previous study (Ferrando et al., 2017), which characteristics of the context of the problem prompt particular solution strategies?

Q2) Does the variation of these characteristics effect students to choose between several solution strategies, or do they always use the same one?

Q3) In what way, when students confront their individual solutions in group and in the physical space posed by a problem, do they arrive at a consensual strategy?

## Methodology

This study, which contained two phases, was carried out during the academic year 2017-2018 with  $n=112$  students from the last course of primary education degree at the University of Valencia. In both phases they have been given the same sequence of problems.

### Phase 1: Individual and purely estimative solution

In this phase of the study, students had to solve the sequence of problems individually. The physical spaces involved in the problems belong to the environment of the Education Faculty and are

familiar to the students, but they do not have any data and they should only explain the procedures about how to get an estimation of the solution. The design of the sequence of problems has been carried out in collaboration with other researchers in the working group and has been based on the results obtained in Ferrando et al. (2017). The analysis of the individual solutions in this phase allowed us to answer the Q1 and Q2.

### **Phase 2: Empirical solution by groups**

In this phase, heterogeneous groups (depending on the solutions obtained in Phase 1) of 3 to 5 students are configured. They had to solve the same sequence of problems as in phase 1 in situ, but this time they must agree on a joint strategy. The analysis of their solutions allowed us to answer Q3 and also complete the answer to Q1. Indeed, we have identified what we call *problem variables*. These variables are related to the size and shape of the elements, the ratio of sizes between element and surface, the shape of the surface and the distribution of the elements on the surface.

### **Implications**

This exploratory study is the starting point of a PhD thesis in which it is intended to analyse the knowledge, use and promotion of flexibility in solving realistic Fermi problem among future teachers. The results of this study can help to lead up to formulate a specific definition of flexibility for the domain of the Realistic Fermi problems and to raise new questions such as: What type of instruction is most effective in promoting flexibility in this class of problems? What is the relationship between the validation of the solution and the choice of the most efficient strategy? When the future teachers solve this type of sequence, does it influence their conception of flexibility?

# Features of modelling processes of group with visual and analytic mathematical thinking styles

Juhaina Awawdeh Shahbari<sup>1</sup> and Rania Salameh<sup>2</sup>

<sup>1</sup>Al-Qasemi Academy & Sakhnin College, Israel; [juhaina@qsm.ac.il](mailto:juhaina@qsm.ac.il)

<sup>2</sup>Al-Qasemi Academy, Israel; [salamerania84@gmail.com](mailto:salamerania84@gmail.com)

*Keywords: Modelling, modelling cycle, visual thinking style, analytic thinking style.*

Mathematical thinking styles denote how individuals prefer to present mathematical tasks, and to understand and process mathematical facts (Borromeo Ferri, 2010). Thus, teachers' awareness of different mathematical thinking styles is particularly important when students are exposed to mathematical modelling activities that offer them the opportunity to meet everyday challenges and demands, and that provide them with the capabilities to deal with real-word situations. Mathematical modelling is the process of translating between the real world and mathematics (Blum & Borromeo Ferri, 2009). Knowledge about students' modelling processes can ameliorate their teachers' interventions (Blum & Leiß, 2005). Though modelling processes have been studied widely almost no studies have focused on modelling processes with respect to thinking styles characterizing groups, in which all modelers have the same mathematical thinking style. This study aims to shed light on the influence of group mathematical thinking style on members' modelling processes while engaged in modelling activities. This leads to the research questions: Do groups of students with different mathematical thinking styles (visual or analytic) differ in their modelling processes while working on a sequence of modelling activities, and if so, how?

## Method

For the first stage of the study, a questionnaire comprised of eight tasks for identifying participants' thinking style was administered to 35 students in an eighth-grade class. We adopted the categories (visual thinking style, analytic thinking style and integrated thinking style) described by Borromeo Ferri and Kaiser (2003) for analyzing students' problem-solving processes. In these tasks, the visual thinking style was characterized by sketches and drawings, while the analytical thinking style was expressed in a formula-oriented task. Based on the thinking styles reflected in solving the tasks in the questionnaire, students were classified as: analytic (14 students), visual (11 students), and integrated analytic and visual (10 students) thinking styles. In the second stage, we selected five students in the analytic group and in the visual group respectively. We made the selection with the assistance of their mathematics teacher, in order to maximize the similarity between the groups. Each group worked on three modelling activities adapted from the literature (e.g., Blum & Borromeo Ferri, 2009). Their work was documented by video recordings and transcribed. We used the constant comparative method to analyze the students' modelling processes, taking into account the cognitive aspect of modelling cycles (Blum & Leiß, 2005).

## Findings

The findings indicate that the analytic and visual groups demonstrated similar features in working on the three modelling activities, but differed in their modelling processes. The analysis of the modelling

processes of the two groups when doing the three activities revealed that the major differences between them were in their real model and their ways of simplifying, mathematizing, and creating a mathematical model. The students in the analytic group tried to simplify the three activities by mathematizing them. In contrast, the visual group tried to simplify the activities by drawing and illustrating. In addition, the findings revealed differences in the illustration of the mathematical model. The findings also indicate that the analytic group went through more modelling cycles than did the visual group to obtain the final model in each activity. In addition, the analysis indicates that the analytic group skipped more of the modelling phases than did the visual group. The modelling cycles of the analytic and visual groups for the same activity are presented in Figure 1 and 2 respectively.

Figure 1: Modelling cycle of analytic group

Figure 2: Modelling cycle of visual group

## Summary

The findings revealed differences in the two groups' modelling processes and in features of modelling cycles. The major difference between the groups was in their ways of simplifying, mathematizing, and creating a mathematical model of the real-world situation. In the light of these findings, it is important to improve teachers' awareness of students' mathematical thinking styles, because this awareness can play a vital role in designing effective interventions for their students who are engaged in modelling activities.

# Professional competencies for teaching mathematical modelling – supporting the modelling-specific task competency of prospective teachers in the teaching laboratory

Raphael Wess<sup>1</sup> and Gilbert Greefrath<sup>2</sup>

<sup>1</sup>University of Muenster, Germany; [r.wess@wwu.de](mailto:r.wess@wwu.de)

<sup>2</sup>University of Muenster, Germany; [greefrath@wwu.de](mailto:greefrath@wwu.de)

*Mathematical modelling has been a mandatory component of the German educational standards in mathematics for the last 15 years. Teachers need a range of cognitive abilities and skills to adequately teach modelling to their students. Within the MiRA<sup>+</sup> teaching laboratory, we focused on supporting the development of the professional competencies associated with mathematical modelling in prospective teachers. Encouraging teachers to design own modelling tasks and apply them in practice successfully aided the development of modelling-specific task competencies with a crucial role in the acquisition of competency by their students. This article presents a promising array of initial results on the development of task competency in teacher education.*

**Keywords:** *Mathematical modelling, modelling task, task competency, teacher education.*

## Introduction

As part of the teacher training project “Qualitätsoffensive Lehrerbildung”, the University of Muenster has created learning opportunities in the form of practical sessions with structured reflection to equip prospective teachers with productive ways of managing heterogeneous learning groups. Teaching-learning laboratories provide invaluable opportunities to incorporate practical elements that specifically facilitate the professionalisation of prospective teachers at an early stage of their studies by hosting interactive reflection on teaching-learning processes. In the spirit of a potential-driven approach to managing heterogeneity in the classroom, this allows teachers to gain experience working with groups of students who display different levels of individual performance, e.g. by testing and discussing differentiated learning materials and varying the instructions given to specific students.

From the perspective of mathematics education, mathematical modelling processes are inherently good at organically differentiating between students. Open modelling tasks represent a constructive heterogeneity management strategy that allows students to work individually and in a differentiated manner according to their own prior knowledge, interests, and performance levels. However, despite its extensive potential, mathematical modelling is found to be challenging by both the students themselves and their (prospective) teachers (Blum, 2015). As a result, a detailed study of the teaching competencies needed to support mathematical modelling is urgently needed by the current quality development initiatives in teacher education.

This paper studies the development of modelling-specific task competency, which is viewed as one of the aspects of professional competency for teaching mathematical modelling, in the teaching laboratory MiRA<sup>+</sup> (mathematics in real applications) attended by university candidates during the first phase of teacher education.

## Mathematical modelling

Mathematical modelling is the basis of the teaching-learning processes facilitated by the MiRA<sup>+</sup> teaching laboratory. Realistic settings provide an abundant source of authentic problems that can be solved mathematically and then reapplied to the original context. Modelling is defined as “the process leading from a[n] [authentic] problem situation to a mathematical model” (Blum, 2002, p. 153). The following section presents some of the theoretical and pedagogical background of modelling, introducing a few ideas that will be essential for the subsequent discussion.

### Modelling as a competency

Mathematical modelling is one of the six general-purpose mathematical competencies encountered at every level of the German educational standards. Students are expected to be capable of translating problems from reality to mathematics and vice versa, as well as being able to work mathematically within the model itself. Blum (2015) defines modelling competency as the ability to construct, exploit, or adapt mathematical models by executing each step of the modelling process adequately and appropriately for the given problem, together with the ability to analyse and critically compare specific models. The student’s ability to carry out specific subprocesses can be viewed as the subcompetencies of mathematical modelling (Niss, 2003). Table 1 characterises selected subcompetencies in accordance with the modelling cycle by Blum and Leiss (2007).

Subcompetency	Indicator
Constructing	Students construct their own mental model from a given problem and thus formulate an understanding of their problem
Simplifying	Students identify relevant and irrelevant information from a real problem
Mathematising	Students translate specific, simplified real situations into mathematical models (e.g., terms, equations, figures, diagrams, and functions)
Interpreting	Students relate results obtained from manipulation within the model to the real situation and thus obtain real results
Validating	Students judge the real results obtained in terms of plausibility

**Table 1: Selected subcompetencies of modelling (Greefrath & Vorhölter, 2016, p. 19)**

Working mathematically itself is not explicitly listed as a modelling subcompetency, since it is not specific to modelling processes and is therefore not specifically emphasised when teaching mathematical modelling.

### Modelling tasks

Tasks represent a strongly dominant component of mathematical teaching. The communication of mathematics to students during the teaching-learning process has always heavily relied on setting and solving tasks (Neubrand et al., 2011). More concretely, modelling processes can be stimulated in the classroom by setting suitable tasks. Various categories of tasks can be defined to analyse and classify modelling tasks. For example, Maaß (2010) proposes a comprehensive classification of modelling tasks that considers the nature of their reference to reality, their openness, and their focus on modelling activities, among other criteria. Greefrath, Siller, and Ludwig (2017) refine the criterion of “reference to reality” by considering the authenticity and the contextual relevance of

each task in further detail. For the criterion of “focus on modelling activities”, they adopt the modelling subcompetencies listed above. Building upon this theoretical background, we compiled the list of criteria (see Table 2) reproduced for the development and evaluation of modelling tasks.

Criteria	Concretisation
Reference to reality	Does the problem refer to an extra-mathematical factual context?
Relevance	Is the factual context relevant to the students (factual problem)?
Authenticity	Is the factual context authentically related to the actual situation? Does the factual context apply mathematics in an authentic manner?
Openness	Is there more than one possible way to solve the problem (solution variety)? Are there different levels of solutions?
Modelling subcompetencies	Which modelling subcompetencies are required to work on the problem?

**Table 2: Criteria for the creation and evaluation of modelling tasks**

### Professional competency for teaching mathematical modelling

To achieve quality development during the first phase of teacher education, a detailed analysis of the professional competencies associated with teaching mathematical modelling needs to be performed. Models that accurately characterize the requirements placed upon teachers must also be formulated to measure these competencies. Research on mathematical teaching is not only concerned with competence models that characterize the general areas of responsibility of educators, for example by establishing a global description of teaching knowledge, but also with professional competence models that focus on specific parts of the educational standards. A collaborative project by the Universities of Koblenz-Landau and Muenster sought to provide some initial structural answers for mathematical modelling by developing an instrument that measures certain key aspects of the professional competency for teaching mathematical modelling (Klock, Wess, Greefrath, & Siller, 2019).

Task-related dimension	a) Ability and knowledge to solve a modelling task in multiple ways b) Ability and knowledge to analyse modelling tasks c) Ability and knowledge to develop modelling tasks
------------------------	-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Table 3: Task-related dimension for teaching modelling competency (Borromeo Ferri & Blum, 2010)**

This conceptualisation is primarily oriented towards the COACTIV model, which gives a description of the professional competency of teachers (Baumert et al., 2010). Formulating modelling-specific interpretations of the competency facets of teaching knowledge identified by this model along the competency dimensions proposed by Borromeo Ferri and Blum (2010) gives facets of modelling-specific teaching knowledge that serve as the basis for the proposed conceptualisation of professional competency for teaching mathematical modelling (Klock et al., 2019).

### Modelling-specific task competency

At a theoretical level, the modelling-specific task competency is directly derived from the task-related dimension in Table 3 and represented in terms of the knowledge facets of modelling tasks specified by the professional competence model for teaching mathematical modelling. The task

competency characterising mathematical lesson planning (Neubrand et al., 2011; Borromeo Ferri, 2018) was found to be significant, not just in relation to the model cited above, but also for the professional competency review of prospective teachers performed as part of the quality development initiative. Thus it became clear that a positive development of this aspect of professional competency in particular helps to overcome obstacles to the use of modelling tasks in the classroom and to exploit their organically differentiating potential in the sense of a constructive heterogeneity management strategy. The general task competency of a (prospective) teacher may be defined as:

“the ability to design and use tasks to cognitively stimulate students and evaluate their learning performance, as well as the ability to analyse the work performed by students on these tasks” (Sjuts, 2010, p. 807).

These abilities, together with an understanding of the diverse pedagogical potential of tasks, represent a key dimension of teaching knowledge. The task competency aspects of teaching mathematical modelling are just as crucial. Properly understanding the multiplicity of possible solutions, cognitive analysis, and the process of developing modelling tasks results in high lesson flexibility and serves as a modelling-specific interpretation of the task competency (Borromeo Ferri, 2018).

## **Research question**

In light of the theoretical discussion given above, the global research objective is to determine the extent to which the professional competencies of prospective teachers in mathematical modelling can be supported by a teaching laboratory. In particular, we are interested in studying any task-related abilities of (prospective) teachers that are relevant to the acquisition of competency by students. The research objective can therefore be formulated more concretely as follows: *To what extent do self-prepared modelling tasks in a mathematical teaching laboratory environment improve aspects of the modelling-specific task competency of prospective teachers relative to well-established modelling tasks?*

## **Methodological approach**

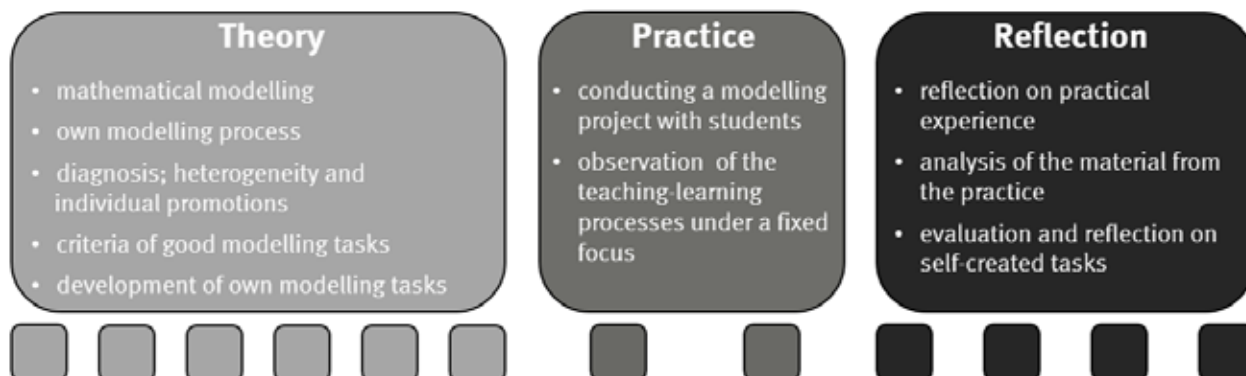

### **Sample and design**

To answer this research question, a paper-and-pencil questionnaire with a pre-post comparison group design was used to collect data from 107 candidates at the Universities of Koblenz-Landau and Muenster who were studying for a teaching position at secondary schools. In addition to the treatment group (TG) in Muenster ( $N=35$ ) and the comparison group (CG) in Koblenz ( $N=43$ ), data were collected from a baseline group in Muenster ( $N=29$ ) to control for any test repetition effects.

### **Teaching laboratory concept**

For this study, based on the concept of a teaching-learning laboratory (Lengnink & Roth, 2016), a series of teaching seminars on mathematical modelling featuring practical components were developed at the two participating institutions. The contents of the seminars were coordinated but emphasised different facets of modelling-specific competency. The seminars in Muenster focused on developing the task-related skills of prospective teachers by asking them to develop and apply

their own modelling tasks. By contrast, the seminars in Koblenz focused on developing modelling-specific intervention competency by applying well-established modelling tasks without analyzing and adapting them. The teaching laboratory MiRA<sup>+</sup> discussed in this paper consists of a theory-based preparation phase, a practical phase, and a reflection phase (see Figure 1).

**Figure 1: Concept of the MiRA<sup>+</sup> teaching laboratory**

Modelling processes represent the core content of every phase, together with sensitisation to potential-driven methods of managing heterogeneity in the classroom. The term “teaching laboratory” reflects the emphasis on teacher education. However, the teaching-learning processes of the university candidates naturally unfold in parallel to the learning processes of the high school students. The theory phase of the seminar serves to impart the theoretical foundations of mathematical modelling and pedagogical diagnostics. The dimensions of heterogeneity are discussed as well as the basics of individual promotion. Finally, modelling tasks for use in the practical phase are developed on the basis of the criteria mentioned (see Table 2). During the practice phase, a small team of prospective teachers look after a small group of high school students to work on the designed modelling tasks. Each team focuses its observations of the teaching-learning processes on subcompetencies of mathematical modelling (see Table 1). After the sessions, implications will be drawn from the insights for the upcoming teaching laboratory appointments, for example addressing a variation of the instructions. The reflection phase serves to reflect practical experiences from the observed teaching-learning processes. The focus is on the managing of heterogeneity in the classroom, the insights gained from it for the professionalisation of the prospective teachers own teaching activity as well as the consequences for the conception and the execution of the own modelling tasks. The aforementioned conception of a teaching laboratory as a seminar with practice integration should especially promote the acquisition of professional knowledge and competency. In addition, the testing of theory-based practical didactic action with regard to the participating prospective teachers is a central element of teaching laboratories. Thus, the acquired didactic and professional knowledge in the development of tasks as well as in the supervision of the students is interlinked and implemented.

### **Test for measuring aspects of professional competency**

An instrument was developed and piloted in the summer semester of 2017 to measure specific aspects of the professional competency for teaching mathematical modelling (Klock & Wess, 2018). The modelling-specific task competency was measured using dichotomous combined-single-

choice items targeting cognitive analysis, solution multiplicity, and the development of modelling tasks. The scale values are based on the standardised sum scores of the dichotomous coding and are examined in a group comparison using a repeated measures analysis of variance for developmental differences. An example of a test item is given in Table 4.

Scale	Number of items	Item example
Task-related competency	12	A. Modelling tasks can be underdetermined.      .. right    .. wrong
		B. Modelling tasks can be overdetermined.      .. right    .. wrong
		C. Modelling tasks should be as closed as possible.      .. right    .. wrong

**Table 4: Example test item measuring the modelling-specific task competency (Klock & Wess, 2018)**

## Results

This section presents the progression of the competency aspects cited above observed in the study participants. There were no significant differences between groups in the facets of modelling-specific task competency at the time of first measurement.

**Figure 2: Analyse modelling tasks      Figure 3: Solve modelling tasks      Figure 4: Create modelling tasks**

Repeated measures analysis of variance reveals that the cognitive analysis aspect of modelling tasks ( $F(1,76) = 12.109$ ,  $p = .001$ ,  $\eta^2 = .185$ ; Figure 2) in the treatment group (TG) at Muenster progressed significantly more favourably with a greater effect size than the comparison group (CG) at Koblenz. For the solution multiplicity aspect of modelling tasks, a significantly higher increase with a larger effect size ( $F(1,76) = 24.322$ ,  $p = .00$ ,  $\eta^2 = .242$ ; Figure 3) was observed in the TG relative to the CG. Similarly, for the development aspect of modelling tasks, the TG displayed a significantly stronger progression with a larger effect size ( $F(1,76) = 12.558$ ,  $p = .001$ ,  $\eta^2 = .182$ ; Figure 4) when measured against the progression of the CG.

No significant changes in the aspects of modelling-specific task competencies considered by this study were observed in the baseline group (Analyse:  $t(28) = 1.154$ ,  $p = .258$ ; Solve:  $t(28) = 1.410$ ,  $p = .169$ ; Create:  $t(28) = 1.797$ ,  $p = .093$ ; see Figure 4). Consequently, there were no test repetition effects.

## Summary and discussion

On the basis of a widely accepted competency concept and a well-established structural model of professional competency, we were able to constructively apply a survey instrument measuring the

teaching of mathematical modelling to prospective teachers in a teaching laboratory. Our study of the modelling-specific task competency, which has a strong effect on the acquisition of mathematical modelling competency by students, found clear signs that the professional competency for teaching mathematical modelling can be successfully enhanced within the teaching laboratory MiRA<sup>+</sup> by encouraging teachers to apply criteria-led self-prepared modelling tasks. Significant contrasts with large effect sizes were observed relative to the progression of the comparison group, which used well-established modelling tasks. These contrasts were concretely measured by the aspects of development, cognitive analysis, and multiplicity of solutions.

### Limitations and outlook of the study

Despite the large effect sizes and the significant differences, the number of participants in the experimental group ( $N = 35$ ) does not provide a sufficiently robust basis for any definitive statements regarding the professional competency for teaching mathematical modelling. The conclusiveness of these findings can be increased in future by cumulating over multiple seminar cycles – provided of course that the treatment is controlled appropriately.

# Horizontal mathematization: a potential lever to overcome obstacles to the teaching of modelling

Sonia Yvain-Prébiski<sup>1</sup> and Aurélie Chesnais<sup>1</sup>

<sup>1</sup> University of Montpellier, France; sonia.yvain1@umontpellier.fr,  
aurelie.chesnais@umontpellier.fr

*Research shows the importance of the development of the learning and teaching of mathematical modelling in secondary school but also highlights some barriers, especially concerning the difficulties of teachers to implement modelling activities. An epistemological study of mathematical modelling and a contemporary epistemological study of modelling experts' practices led us to identify horizontal mathematization as a crucial component of mathematical modelling. Based on this conceptualization, we then came up with a task for teachers to implement in their classrooms, within a professional development program, which provides us some data to study the constraints and conditions of teaching practices concerning modelling. Our results suggest that a teaching strategy stressing horizontal mathematization is likely to foster a consistent modelling activity of students and that teachers don't identify horizontal mathematization as a learning issue.*

*Keywords: Horizontal mathematization, teaching practices, modelling.*

## Introduction

Research in mathematics education shows how developing the learning and teaching of mathematical modelling in secondary school is important, but also points out some hindrances, especially concerning the difficulties for teachers to implement modelling activities in their classrooms. Numerous studies point out some obstacles concerning teaching practices (Schmidt, 2011; Blum & Leiss, 2007; Kaiser et al., 2011; Maaß & Gurlitt, 2011; Ramirez, 2017; Barquero et al., 2018). For instance, mathematics teachers don't consider modelling as an essential component of mathematics learning; they doubt of their own competencies about mathematical modelling; they find it difficult to implement modelling tasks in class in particular because students might come up with a lot of different solutions and identifying what is at stake in such tasks is not easy; choosing an appropriate task is difficult for them. They also find it hard to identify students' difficulties and to evaluate modelling competencies; finally, they say they are lacking time to organize their teaching of modelling. Research on French teachers (Cabassut & Ferrando, 2017; Yvain-Prébiski, 2018) confirms that these international findings also apply to French teachers.

These hindrances mainly concern the conception and implementation of modelling activities in classrooms, which relate to elements formalised as institutional, cognitive, mediatory and personal constraints of teaching practices in the theoretical framework of the double approach of teaching practices of mathematics teachers (Robert & Rogalski, 2005; Vandebrouck, 2013). It leads us to hypothesize that overcoming some obstacles to the effective teaching of mathematical modelling in classrooms implies a more effective conceptualization of the modelling process. A literature review and a contemporary epistemological study of experts' practices in research about modelling in life sciences lead us to identify the crucial role of horizontal mathematization in this process and to characterize some forms of it that could enrich the conceptualization of mathematical modelling in

classrooms. The hypotheses we want to test in our research are: first, a teaching strategy emphasizing horizontal mathematization is likely to foster a consistent modelling activity of students in classrooms; then, despite its identification by teachers as an important component of mathematical modelling, they don't seem to consider horizontal mathematization as a learning issue. In the next section, firstly we present our conceptualization of mathematical modelling, stressing horizontal mathematization as a crucial component of the process. In the second part, we are exposing the theoretical framework we used to study teaching practices and our experimental design. In a third part, we will expose our findings. Conclusion will allow us to design some perspectives about teacher training.

### **Horizontal mathematization: a fundamental component of mathematical modelling**

Mathematics education researchers working on mathematical modelling in an educational perspective, especially in the RME framework (for example, Rasmussen et al. 2005; Barnes, 2005) consider the distinction introduced by Treffers (1978) and Freudenthal (1991), between horizontal mathematization which “leads from the world of life to the world of symbols” and vertical mathematization, as work within the mathematical system itself. In our research, we focused on the teaching and learning of mathematical modelling based on extra-mathematical situations. We then followed the idea of Israel (1996), who defines a mathematical model as “a piece of mathematics applied to a piece of reality” and defined different forms of horizontal mathematization that seem relevant to explore educational issues: choosing a piece of reality to question in order to answer the problem; identify and choose the relevant aspects of the piece of reality (context elements, attributes); relating the chosen aspects together in order to construct a mathematical model; and last, quantification (Chabot & Roux, 2011), which refers to the association of some aspects of reality to quantities (which essentially consists in measuring).

To deepen our epistemological study of modelling, we analysed the practices of experts (researchers) on mathematical modelling in life sciences, through interviews (Yvain, 2017). The main findings consist in the identification of three invariant features in the practices of researchers that contribute to the transformation of reality to mathematical solvable problems. The first invariant, which we labelled  $P_{i1}$ , consists in simplifying the problem and selecting a piece of reality. It supposes to identify relevant variables and choose relevant relations between the selected variables. The second invariant  $P_{i2}$  consists in choosing a model among those known by the researcher in order to initiate vertical mathematization, at the risk of further having to refine or reject the initial model. The third invariant consists in quantifying in order to compare the “real data” with the results obtained within the model. We assume that taking into account horizontal mathematization in the teaching and learning of modelling is likely to foster students' competencies.

### **Theoretical framework for the study of the teaching and learning process**

Our conception of learning relies on the idea that students' learning depends on their activity which results from the tasks they have to solve in class. However, we assume that solving a task is not enough to guarantee conceptualising. Indeed, the role of the teacher is also to allow students to identify mathematical knowledge in their activity to ensure the “transformation of activity into

learning”. We will then consider that actively practicing horizontal mathematization when solving the task would constitute a first step on the way to the appropriation by students of horizontal mathematization within the process of modelling: it corresponds to a “local devolution” (Perrin-Glorian, 1997) of this learning issue. Considering that the devolution of it is complete (and hence that substantial opportunity for conceptualising is offered) supposes that the knowledge at stake is explicitly identified – by the teacher – as something to be learned (i.e. remembered in order to use it again later).

Our theoretical framework to study teaching practices is the double approach of mathematics teachers’ practices, developed by Robert and Rogalski and their followers (Robert & Rogalski, 2005; Vandebrouck, 2013). Teaching practices are considered as complex, embedding five components. The first two of these are the cognitive and mediatory ones, which are directly observable in classrooms. The cognitive one corresponds to the teacher’s choices regarding content and tasks, including their organization. Choices corresponding to class events and to the effective implementation in classrooms of the tasks make up the mediatory component. The three other ones are the social, institutional and personal components, which allow taking into account elements that crucially impact some choices made by teachers. This framework leads us to investigate constraints that are more likely to impact teachers’ choices, would it be related to personal, social or institutional constraints. First, institutional constraints are essentially related to official instructions. Then, we have conducted analyses of classroom sessions, considering both the cognitive and the mediatory components of practices, and analyses of questionnaires filled by teachers during the development program, which allowed us to make some hypotheses on personal and social constraints.

## Experimental design

Relying on our epistemological study, we tried to characterize tasks likely to support the learning of horizontal mathematization and hence students’ activities inspired by  $P_{11}$ - $P_{12}$  and  $P_{13}$  practices. Such tasks should then be “realistic fictions” conceived as adaptations of a professional modelling problem. Here is an example of such a task that we designed for our experiments:

**Figure 1: Text of the task “The tree”**

In order to have teachers implementing this task in their classrooms, we worked with a group of teachers in the context of a professional development program about mathematical modelling<sup>1</sup>. Not

---

<sup>1</sup> This program has been existing for ten years and was designed by a group where researchers and some teachers work collaboratively (one of the two authors of this paper is part of the group). Every schoolyear, this program offers a collaborative project to volunteering teachers with their classes from 6th grade till the end of secondary school.

only shall the program include the fact of asking teachers to implement the task in their classroom, but it will also do it with a specific scenario. The scenario included five sessions. Groups of three classes were conformed and all the classes interacted using a platform regulated by the designers of the program. We will not give more details about the professional development program (see Yvain & Modeste, 2018, for more details) except for one point which we will linger on in this paper: the original first phase of “questions-and-answers”. The first step of the scenario requires teachers to devote the first session to students asking questions about the problem, to send them to two other classes and then to devote the second session to trying to answer those questions.

### Collected data and methodology

In order to identify constraints related to the institutional component of teaching practices, a preliminary study of French official instructions for secondary school allowed us to identify the importance of mathematical modelling as a learning issue, but it remains a lot of implicitness about the role of horizontal mathematization in this process (Yvain, 2018). To explore the cognitive and mediatory components of teaching practices, we collected videos of the sessions in the classrooms of three teachers who took part to the program. We postulate that if teachers identify the learning issue related to horizontal mathematization, we would find traces of it in the cognitive and mediatory components of their practices, in the way they introduce the questions-and-answers phase to students and in the content they summarize at the end as what should students remember. We then designed four levels that indicate how much this learning issue is identified by teachers, according to what they had said during the introduction phase and the closing phase. These indicators are based on the forms of horizontal mathematization described above.

Identification of horizontal mathematization as a learning issue	In the introduction phase	In the closing phase
Level 1: no identification	No element indicating the function of the questions-and-answers phase in the solving of the problem	The teacher doesn't make a summary of what should be remembered or the summary doesn't mention anything related to horizontal mathematization.
Level 2: vague identification	Some elements indicating the function of the questions-and-answers phase in the solving of the problem	The summary includes the idea that some information was missing in the initial problem to be able to solve it.
Level 3: partial identification	Elements inducing the idea of the necessity of making choices	The summary mentions the necessity of making choices in order to be able to solve the problem.

Level 4: complete identification	Elements inducing the idea of the necessity of making choices on context features and about relevant attributes to model the problem. Idea that modelling the problem will depend on the choices made.	The summary mentions the necessity of making choices in order to be able to solve the problem and explains that different models could be used to solve the problem. The summary mentions the importance of choosing relevant attributes, depending on the problem to be solved, in order to choose a model.
----------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Table 1: Indicators of the identification by teachers of horizontal mathematization as a learning issue**

## **Findings: A task and a strategy effectively supporting students' activity of horizontal mathematization**

### **Findings concerning students' activity during the phase of questions-and-answers**

The analysis of questions and answers produced by students shows that they made simplifying hypotheses to handle the problem by selecting one or some pieces of reality: they focused on branches, the greenhouse, the leaves etc. They identified relevant variables that impact the real situation (for example, the number of branches) and non-relevant variables or elements of context (possibility to use organic fertilizer, or leaves); they chose relevant relations between the selected variables and used several mathematical tools (functions, proportionality, and geometry). These activities attest that students implemented  $P_{11}$ -like activities.

Students also identified the necessity of modelling the situation to be able to predict the tree's growth. Students authentically questioned the variables to choose in order to solve the problem mathematically. The realistic aspect of the situation lead them to reflect on the important elements of context to be taken into account. This also helped them understand that not all information on the real context was useful to solve the problem or that it was suitable to ignore them in order not to come up with a too complex model. Our analysis showed that students mainly tried to use models that they knew (particularly, those using proportionality) and that they sometimes rejected it when they confronted the results they obtained to contingency, which attests their ability to implement  $P_{12}$ -like activities.

Finally, the mention of the scale in the text of the task allowed students to use instruments to make measures, which lead them to quantify some attributes and confront measures with real data, which attests of  $P_{13}$ -like activities. The analysis of traces of students' activities allows us to conclude that the characteristics of the task and the questions-and-answers phase fostered activities of students that resemble experts' practices and correspond to horizontal mathematization. This attests that the first level of devolution of horizontal mathematization was reached. However, what it still remains open for future research is how students responsibility was really involved in these activities and to what extent this issue was identified by teachers in a way that allows a full devolution of the learning issue.

## Analyses of teachers' practices

The analyses of the classroom sessions we observed, with the study of answers teachers provided to a questionnaire during the development program, show that the impact on the motivation of students. The main advantages that teachers identify are the collaborative aspect of the questions-and-answers phase and the fact that this phase develops a better appropriation of the problem by students. About the mediatory component of teaching practices, the analysis of the different implementations show that teachers encourage students to produce questions and then answers in order to solve the problem. This is what guarantees the local “devolution” of horizontal mathematization to students, during the questions-and-answers phase. However, when considering teachers discourse during the introductory phase, it appears that the purpose of the questions-and-answers phase is not completely explicit. Two out of the three teachers discourses correspond to level 2 (see the first excerpt below) and one to level 3 (see the second excerpt below). Note that none of the teachers we observed attained level 4, neither for the introductory phase nor the conclusion phase.

- Teacher 1      Your job is to come up with questions, things that you didn't understand, things that are missing, ok, here we miss some information, we need to know this or that to try to answer, or to clarify some things, you decide.
- Teacher 2      The challenge of the session is to try to provide some elements of answer. Do you have an opinion, an answer to propose? What is your point of view? Ok and if you had to make choices, which choices would you make? Because in my opinion, some choices are necessary or they will never be able to do anything.

During the concluding phase, two teachers discourses correspond to level 2 (“the aim was to focus all the classes on the same problem in order to have everybody researching the same thing and to give you more information to proceed.”); one teacher's discourse corresponds to level 3: “modelling is what we have been doing all along: making choices, ok? ” All in all, even if some teachers mention the necessity of making choices to solve the problem, they don't seem to identify this necessity as a learning issue. In particular, they never offer students any formalization of the knowledge at stake about horizontal mathematization. Based on our theoretical framework, this makes us conclude that the devolution of the learning issue constituted by horizontal mathematization is not complete.

## Discussion and conclusion

Our research shows that a conceptualization of mathematical modelling stressing the process of horizontal mathematization allows us to deepen our understanding of the learning and teaching issues related to mathematical modelling. Such conceptualization provides tools to support building efficient teaching strategies in order to guarantee consistent students' activities of horizontal mathematization. These strategies include, in particular, a questions-and-answers phase that seems to play a fundamental role. Let us note that these conclusions meet the preoccupations of other researchers working on the same subject. For example, the MERIA project also stresses the opportunities offered by a questioning phase in order to develop some skills about modelling.

However, our study also suggests that teachers, even if they identify the necessity of making choices in mathematical modelling, don't completely understand it as a learning issue. Yet, this appears as a

condition for the complete devolution of the issue, in order to have students practice horizontal mathematization in ordinary classes, i.e. when teachers are not engaged in specific programs, imposing them teaching strategies. It leads us to postulate that a conceptualization of mathematical modelling in a way that includes horizontal mathematization, as a crucial and explicit component, would also constitute a good tool for teachers in order to overstep some of their difficulties and to improve their teaching skills about mathematical modelling – and hence, to improve learning. Our perspective is then to enrich our professional development program with an explicit work on horizontal mathematization with teachers and to make them able to identify it as a learning issue and as a tool to support the full devolution of it to students. For example, we suppose it would be fruitful to work with teachers on building summaries of such classroom sessions, suggesting them that elements about the necessity of making choices on relevant attributes and context elements in order to be able to model a situation and solve a problem would be valuable to explicit with students. Our research constitutes only a first step but points out a potential fruitful approach of teacher training about mathematical modelling, provided that teaching practices are considered in their complexity.

<sup>1</sup>HU University of Applied Sciences Utrecht, The Netherlands; [kees.hoogland@hu.nl](mailto:kees.hoogland@hu.nl)

<sup>2</sup>University College London, United Kingdom; [beth.kelly@ucl.ac.uk](mailto:beth.kelly@ucl.ac.uk)

<sup>3</sup>University of Barcelona, Spain; [jdiezpalomar@ub.edu](mailto:jdiezpalomar@ub.edu)

*This paper is a summary paper of the Thematic Working Group (TWG) on Adult Mathematics Education (AME). The theme AME made its first appearance on CERME11 and in this paper we provide an overview of the growing and blossoming field of AME and the results of the working group. The main themes associated with AME are: the definition, scope, and assessment of numeracy, the role of language and dialogue, the role of affect, including motivation, and the role of societal power structures, including subthemes like equity, inclusion, vulnerable learners, agency and self-efficacy. We conclude with the opportunities and challenges for this theme from both scientific and societal perspective.*

*Keywords: Adult Mathematics Education, Numeracy, PIAAC, Language, Agency.*

### Introduction

Adult mathematics education is a fast growing tree in the mathematics education forest. Many countries have in recent decades adopted policies on lifelong learning and, in most cases, mathematics and numeracy are included in these policies (see for instance the Lifelong Learning Platform, [llplatform.eu](http://llplatform.eu)). This is a consequence of the rising awareness that the current society is rapidly changing due to technological, digital and environmental developments, and that citizens need a broad repertoire of mathematical knowledge, skills, and confidence to deal with those changes, both in work situations as in daily life.

This idea is not completely new. An increasing interest in the relevance of mathematics needed for a well-functioning citizen started in the late 1950s in the UK with the Crowther report (DES Department of Education, and Science, 1959) but really blossomed two decades later with the Cockcroft report (DES Department of Education and Science, 1982), the foundation of Adults Learning Mathematics – an international research forum (ALM) established in 1993 with a strong European input (see e.g., Safford-Ramus, Keogh, O'Donoghue & Maguire, 2018), and the start of the Adults Numeracy Network (ANN) established in 1994 with a main focus on the USA. Numeracy was at that time defined in the Crowther report (1959) as scientific understanding and thinking quantitatively and in the Cockcroft report (1982) as the capacity to understand and use basic principles of mathematics and science presented in mathematical terms.

With the rapid growth of adult education in the 1970s (Milana & Nesbit, 2015) we witnessed a rise in formal mathematics education for adults, as a result of growing opportunities for adults to take another chance in getting mathematics certificates for further study or new careers. During this time, a large part of adult numeracy and mathematics education took place in informal and non-formal education environments, for instance in community centres or in the workplace, or was

hidden in vocational or literacy courses for adults, which made it hard to get a complete overview of the field. Therefore, the mathematics referred to in AME has many appearances. It ranges from formal mathematics for advanced technological careers, to typical school mathematics content supporting the attainment of formal certificates and diplomas, and to the multifaceted concepts of mathematical literacy and numeracy, which deal with the use of numbers, patterns and structures in daily activities. This last appearance can also be described as *Numeracy as a social practice* (Yasukawa, Rogers, Jackson, & Street, 2018). This makes the concept of numeracy relevant to large segments of the populations in many countries; Indeed, the results of the Programme for the International Assessment of Adult Competencies (PIAAC), discussed in the next section, found that many adults have their optimal functioning in daily life hampered by numeracy problems.

In this paper we show the subthemes raised by the participants in the TWG on AME. We consider this TWG as new platform for scientific discussion to push AME towards a more recognized position within the scientific international community. We present a brief summary of each of the contributions presented in the TWG during the conference. Finally, we conclude with some remarks on new avenues and challenges for the research in AME in the forthcoming years.

### **Emerging themes in Adult Mathematics Education**

In TWG07 on AME the breadth and depth of the emerging field of AME is mirrored. Contributions come from various backgrounds, cultures, and experiences. In the first working group discussion the various themes of the contributions were made explicit and put into categories.

These are the categories covered by the contributions of the participants in this TWG:

- The definition, scope, and assessment of numeracy;
- The role of language and dialogue;
- Affect, including motivation;
- Special groups and vulnerable learners;
- Teaching and learning activities, including vocational education;
- The role of power structures, inclusion, agency and self-efficacy.

These themes more than anything else make clear that AME is a multi-layered phenomenon and much more than just mathematics education for a special target group. Mathematics education for adults intertwines the learning of mathematics with language and dialogue, affect, and dealing with learners' reality, but also with societal power structures and sociological concepts like equity, inclusion, and agency.

#### *Regarding the definition, scope and assessment of numeracy*

"Adults' numeracy and literacy practices matter" (p. 75) is the opening line of the chapter by Coben and Alkema (2018) in the ICME13-monograph series title Contemporary Research in Adult and Lifelong Learning of Mathematics – International perspectives (Safford-Ramus, Maaß, & Süss-Stepancik, 2018). This brief sentence summarizes in the shortest possible way the importance of the theme numeracy in the field of AME.

The results of the last PIAAC survey show that in all but one participating country, at least 10% of the adults are proficient below level 1 of the 6-point scale in literacy or numeracy (OECD, 2013;

PIAAC Numeracy Expert Group, 2009). In other words, significant numbers of adults do not possess the knowledge, skills and confidence to succeed in today's society regarding quantitative matters. These results on numeracy give rise to serious concern for the economic development of Europe. This is an even more pressing issue since the amount of numerical data that needs to be interpreted and used is rapidly rising and all pervasive due to technological developments and the prevalence of (big) data. To gain a better insight in these trends a second cycle of PIAAC will be starting in 2021, which is now in preparation (Tout et al., 2017).

David Kaye, chair of ALM, made a contribution to the discussion in the group on the development of the definition and historical development of the concept of numeracy, based on his earlier publications in an ICME13 monograph (Kaye, 2018). In the Crowther report (1959), numeracy was closely related to understanding science and developing technologies in society. In the next twenty years, the meaning changed to basic operations, whereby the association with science was no longer present and the level of mathematical understanding to which numeracy refers became much lower and not much more than “able to perform basic arithmetic operations”. The persistence of the latter definition makes it hard to develop, disseminate, and implement a concept of numeracy which better equates to an ability to cope confidently with the mathematical demands of adult life. For that purpose this latter definition is much too restricted because it refers only to more mechanical and lower-order skills like performing arithmetic operations and not ‘mathematizing’, which is the skill of translating an encountered problem into an adequate operation so that the mathematics can be used with confidence to cope with practical everyday situations. What is so significant about these shifting definitions is that the debate about what numeracy might include was already twenty years old in 1982, and that the tension between numeracy being little more than arithmetic versus being a significant part of everyone's social practice is still being repeated in debates on numeracy policy development. The continuing tension can most likely be explained by the fact that it is not just an academic and educational debate, but rather a political one. In many countries we see a reoccurring ‘back-to-the-basics’-movement as a simple answer to the complex issue of how to prepare children and adults to deal with situations in everyday life which involve numbers, patterns, and structures.

Two contributions especially address this issue too. Diez-Palomar, Hoogland, and Geiger are members of the PIAAC Numeracy Expert Group, which is responsible for the development of an assessment framework and the items in the next PIAAC international comparative assessment, which is happening from 2021 onwards. They performed a limited literature review to explore which concepts from mathematics education theories could enrich the numeracy framework to make it more appropriate to adults functioning adequately in our number-drenched society (Tout et al., 2017). The most relevant concepts taken into account are number sense, big ideas in mathematics, and embeddedness and authenticity. Common in these concepts is that they all acknowledge the richness and multifaceted aspects of adults' cognitive processes in dealing with numeracy situations.

Furthermore, Hoogland, Auer, O'Meara, Diez-Palomar and Van Groenestijn report in their contribution on the first steps towards creating a *Common European Numeracy Framework (CENF)* for adults. These steps are made in an Erasmus+ project with the same name, which started in 2018, and is aims to broaden the perspective on numeracy, foremost by considering numeracy as a social

practice, focusing on numerate behaviour and numeracy practices. For a much more sophisticated discussion on seeing numeracy as a social practice, we further refer to the work of Coben and Alkema (2018) and Yasukawa (2018).

*Regarding the role of language and dialogue.*

The importance of the role of language and dialogue in AME was emphasised by no less than three contributions by Griffiths, Wessel, and Diez-Palomar & Anagnostopoulou respectively.

Griffiths report on his investigations into discussions that took place during and following a particular small group activity in which a scene is read aloud and a mathematical task is undertaken. In his research, the concept of ‘thinking as communication’ is utilised and employs an overarching framework for analysis. To understand what happens when the ‘reading aloud’ activity is undertaken, it is important to investigate what happens when learners undertake related activities. Griffiths describes the key elements to the research with some initial analysis drawing on data from an exploratory phase along with observations from the main study.

Wessel gives an overview of an Erasmus+ project that aims to empirically identify the potentials and challenges of language-responsive teaching designs for low-achieving students in vocational contexts. Using topic-specific designs the research delivers first insights into developing and experimenting with two teaching units (percentages and proportional reasoning) and summarizes the questions that come up when adapting design principles for language-responsive mathematics to the teaching and learning in vocational education. The empirical investigations are carried out with young adult pre-apprentices in lower level vocational education in Germany in the technical sector. These young adults often struggle with mathematics and have only limited proficiency in the language of instruction.

Diez-Palomar and Anagnostopoulou discuss the effectiveness of dialogic learning as an adults’ learning theory. Their paper specifically focuses on how so-called *Mathematics and Physics Dialogic Gatherings* can enhance the critical thinking of adult learners and hence develop their learning in both topics. Two studies were considered where the participants engaged in dialogic reading activity reading classics in mathematics or physics. The former study took place in Barcelona, Spain and involved adult women of above 40-years-old with low literacy skills engaging in mathematics. The latter took place in Kendal, UK and involved two groups of adults. Although the samples were extremely diverse, the results indicate that using classical readings can significantly improve critical thinking and dialogic talk in all groups and provide the potential to create further learning opportunities.

*Regarding affect, including motivation*

In various contributions, attention is given to the role of affect as an important factor influencing the outcomes of AME in the classroom. It acknowledges that learning mathematics involves not only cognitive processes, but also, to a substantial level, an array of psychological and affective factors.

Kelly undertook extensive doctoral research on the role of motivation in AME. Her research is based on interviews with adults about their motivation to study mathematics in the workplace, through classes organised and funded by trade unions in the UK. The findings point to motivation

as a function of individual's emotions and cognition that are influenced by social experiences. The research identifies a difference between the initial motivation to re-engage with learning and that required to continue, or persist. Continuing learning relies on a socially and emotionally supportive learning environment which adults identify as 'different' from previous learning experiences. The term 'Affective Mathematical Journey' is developed to describe the positive emotional changes experienced by adults, which helps them overcome negative memories. The adults' resultant increase in confidence and motivation encourages them to successfully develop and use their mathematical skills both inside and outside the classroom.

#### *Regarding special groups and vulnerable learners*

Engaging in mathematics education as well as trying to improve the management of various numeracy situations, such as finances, is a big step for many adults, especially when their past experiences with education are negative.

Redmer used PIAAC data to get a better insight into the numerate behaviour of older people. Demographic changes render basic numeracy skills increasingly important in older age. Among them, skills in financial matters are increasingly relevant. The skills measured in PIAAC and Competencies in Later Life (CiLL) represent comprehensive cognitive abilities that can be seen as the basis for successful participation in social and economic life. In a secondary analysis, Redmer shows that financial practices continue to be important for older people, although their numeracy skills proficiency may be lower than those of younger people. The analysis clearly indicated a gender difference in dealing with financial matters: men handle bills and bank statements, whereas women manage the household, although there was some discussion about whether this distinction would continue in following generations.

Byrne did research on a very special group. Her exploratory study is part of a larger study on assessment and teaching in mathematics classrooms in Irish prison education centres. Her purpose is to enhance knowledge in this field, to enhance practice and to enable better learning and teaching through research. A so-called Mathematics Teaching Triad is used as a theoretical construct for the study. This triad looks at management of learning, sensitivity to students, and mathematical challenges. When finished, the research project will present data derived from a wider investigation, including data from teachers in the secure sector across Ireland and data from prisoners attending mathematics classes. In this paper Byrne analyses the data gathered from a survey on small sample of teachers, covering the time available for mathematics classes, class composition, teacher satisfaction and teacher's identities through metaphor.

#### *Regarding teaching and learning activities*

Keogh reports on developing and validating an instrument to let people recognise their own numerate behaviour. His reasoning is that adults know more about mathematics than they think and use it more often than they realise. Despite their apparent self-perception of being a 'non-maths' person, they behave in mathematics-informed ways, which are dismissed, routinely, as common sense or something other than mathematics. The doctoral research found that given the opportunity to reflect on their own behaviour at work, through a mathematics-sensitive lens, people readily recognise their numerate behaviour even if they talk about it in different ways. This work introduces

a set of tools and a methodology to harvest real tangible benefits for the learner. The tools explore the locus of a person's expertise in increasing granularity, building a platform from on which to capture a learner's mathematics knowledge, skills and competence, to help revise possible mistaken self-perceptions and to inculcate confidence in his/her learning of mathematics.

Hoogland, Heinsman and Drijvers report on conducting a literature review on how numeracy is used in vocational education and whether there are effective practices identified in peer-reviewed literature of the last five years. The rationale for this study is that numeracy and mathematics education in vocational education is under pressure to keep up with the rapid changes in the workplace due to developments in workplace mathematics and the ubiquitous availability of technological tools. Vocational education is a large component of education for 12- to 20-years-olds in the Netherlands and the numeracy and mathematics curriculum is on the brink of a reform. Preliminary results show that in most of the articles the concept of numeracy was not clearly explained, however when specified the PIAAC definition is used. In the search for articles on numeracy education practices which also reported on effects of those practices, only four such articles could be found out of more than 600 publications on numeracy and vocational education. Discussion in the group suggests a wider search of publications which includes practices involving problem solving, motivation, and math-anxiety.

*Regarding the role of power structures, inclusion, agency and self-efficacy*

Last but certainly not least is the notion of the use of numeracy in society, including the importance of being numerate, equity in access to relevant numeracy education and the perception of gender issues around mathematics and numeracy, all of which are never value-free. In her research Heilmann uses adults' numeracy skills in the PIAAC data to analyse the issue of power. She states that theoretical discussions increasingly view numeracy as embedded in power relations, and if this is the case, these power relations should be visible in the results. She gives an overview of the underlying theories, focusing on three elements of numeracy skill proficiency: the distribution of skills in society, the process of defining a hegemonic view of numeracy skills and finally, the value of numeracy skills in the context of power relations. The value of numeracy skills is analysed using the example of gender relations in the labour market. The analyses explores how gendered hegemony might influence the way numeracy skills matter in terms of monthly wages and the probability of getting into leadership positions.

## **Forwarding the field**

Although there is a broad acknowledgment that an array of psychological and sociological factors are important in (the results of) adult education, there is not yet a well-researched set of examples how in practice this can be taken into account in a more systematic and effective way. The practice of adult numeracy education is still a plethora of different content descriptions and goals that vary from very back-to-the-basics to very sophisticated higher-order skills. Reported teaching practices and lesson materials for adults are quite often not very different from those used in primary schools. Research-validated practices explicitly addressing the psychological and sociological issues are still very rare. The twin goals of trying to establish a firm definition of numeracy which acknowledges

the multifaceted nature of adult's mathematical practices while identifying consistent teaching approaches should be of concern to the global AME community.

Currently in Europe there are some developments which are promising to come to a more common definition of numeracy and identify effective teaching approaches. The ALM organisation is strongly anchored in Europe and functions through its yearly conference in July as a community of practice for researchers in the field of AME in Europe and beyond. The European Basic Skills Network (EBSN) in combination with the EPAL-website of the European Union provides a platform where practitioners, policy makers and researchers can share their ideas, thoughts and results. Furthermore, in 2018 an Erasmus+ project started, which originated in The Netherlands, Austria, Ireland, and Spain, and is aiming to involve all European countries in an attempt learn from each other experiences to find some common ground for terminology, perspectives, development and practice, and policy making .

In the future, it could be helpful if national and regional level policy documents explicitly define and openly discuss the chosen definitions of numeracy in relation to the European or world-wide used definitions, like the one by OECD in the PIAAC programme. Especially when societies become globalised, as Safford-Ramus, Misra and Maguire (2016) advocate, numeracy must remain a dynamic concept that recognises and responds to changes in society.

## Conclusion

AME plays a vital role in empowering individuals to fulfil their full potential, enriching their repertoire to cope with situations and problems in daily life and the demands made by a globalised world, increasing reliant on technology. In the second cycle of PIAAC, which will be conducted from 2021 onwards, a large body of data will become available, which will for the first time provide a longitudinal comparison with the results of the first cycle of PIAAC. To some extent, this will also point to trends in the development of give aspects of the field of AME

Despite the relevance of numeracy in our society, the role that AME plays in the field of research into mathematics education is still rather small. There are international research associations in AME, but the main educational mathematics conferences that are referents in the field do not usually include AME as working group. We have over seventy years of “numeracy” as research topic devoted in national and international reports and studies. In the last decade, results of important large-scale surveys such as PIAAC have becoming available. However, there are still numerous gaps in terms of research understanding how adults learn and use mathematics, develop their quantitative understanding of everyday facts or situations, understand particular mathematical objects (proportions, functions, big numbers, shapes, etc.), and their properties, relationships and representations. The themes identified in this CERME working group layout a possible research agenda. The discussion will continue on the scope and definition of numeracy. Furthermore, sociological aspects will remain in the foreground of discussions on AME, such as its relationship with societal power structures and promoting individual inclusion, agency and self-efficacy for special groups and vulnerable learners. Another important aspect in AME is that adults bring their own life experiences to the learning environment, which implies that teaching and learning is influenced by a broad range of factors including the recognition that motivation to learn is

developed through social and emotional experiences, while teaching activities need to be sensitive to the role of language and dialogue as well as relevant to the context of learners' lives.

When finished, this research project will present data derived from a wider investigation, including data from teachers nationwide and data from prisoners attending mathematics classes. This paper analyses the data gathered from a survey on small sample of teachers, covering the time available for mathematics classes, class composition, teacher satisfaction and teacher's identities through metaphor.*

*Keywords: Assessment, mathematics, prison time, metaphor.*

### Introduction and context

#### Irish Prison Education

The Council of Europe document *Education in Prison* (1990) states that education of prisoners must “be brought as close as possible to the best Adult Education in society outside” in philosophy and content and that it must “link prisoners to the outside community” (p.14).

Prison education in Ireland is a partnership between the Irish Prison Service and the Education Training Boards (Irish Prison Service 2016). The Joint Strategy Statement states that its aims are to

assist persons in custody to cope with their sentences, to prepare for life after release, to develop an appetite and capacity for lifelong learning and to achieve their full potential as learners. It also aims to promote the importance of prison education. (IPS, 2016, p.6)

So prisoner learners can access similar education and accreditation to learners in adult education elsewhere, through accredited (leading to state certification) and non-accredited courses (not leading to state certification). An adult education approach is followed in prison education which looks at the whole person rather than deficit models, which see the student's weaknesses or mainly as an offender (Warner, 2007).

#### Teaching in Prisons

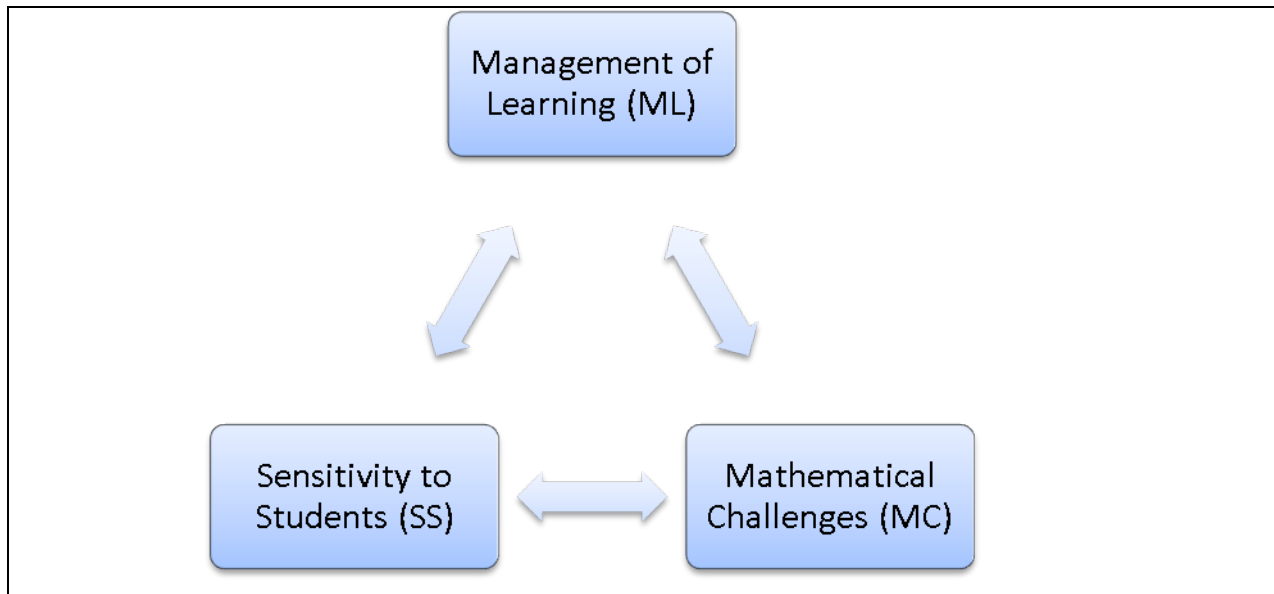

Students entering prison education may have low levels of education (O'Mahoney, 1977; Kett & Morgan, 2003) and a history of negative or disrupted educational experiences (Muth, 2008).

People are motivated to start education in prison for many reasons, including personal development, family and work preparation (Costelloe, 2003). School in prison represents freedom, an escape, a distraction and stops them from sinking (Behan, 2014). They come to have a laugh, make the most of their time, and to learn how to learn (Carrigan & Maunsell, 2014). In prison education they feel trusted (Behan 2014), feel normal and their true selves (Carrigan et al., 2014). The positive feelings of the students seem to have an impact on the teachers. Prison teachers interviewed by Michals (2015) were positive about their work, felt satisfaction and felt that they had learnt from their students. Muth (2008) and Byrne & Carr (2015) state that teachers in prison have noted the transformative nature of prison education, and the growth of their students. This may lead to teachers feeling empowered in the classroom, as Messemer (2013) states that teachers interviewed in US correctional education centers felt they had a strong level of influence to make the necessary instructional decisions in their classrooms. We decided to investigate if there were other reasons for mathematics teacher feeling satisfied in their work. As classes in prison are generally longer than in schools outside, we adapted a study on this topic with mathematics teachers in secondary schools. This found that longer more frequent classes increased teacher satisfaction, which led to increased innovation in methodology and more teaching for understanding (O'Meara & Prendergast, 2018).

### **Why I am doing research?**

Our study is based on the Jaworski Teaching Triad (Jaworski, 1992) which has three components, the Management of Learning (ML), Sensitivity to Students (SS) and Mathematical Challenges (MC). We chose this because it offers a framework for all the proposed data from this study, both qualitative and quantitative. ML refers to the role of the teacher in the classroom learning environment. In this context this refers to groupings, timetable, resources, interactions. Sensitivity to Students (SS) describes the teacher's knowledge of the learners, attention to their needs, affective, cognitive and social. In this context it describes the engagement with students, from the point of entry. Mathematical Challenges (MC) describe the challenges offered to the learners to help them develop mathematical thinking through tasks, questions and reflections, in accredited and non-accredited tasks.

The domains are interlinked and interdependent. A balance between SS and MC is needed to enable teaching to take place. In prison education there could be a risk of too much SS, due to vulnerability of learners, and too little MC which could mean strong relationships in class but little mathematical progression. Too much MC and too little SS could cause stress to an already traumatized and stressed group. Harmony leads to achievement when there is a balance between challenge, support and stimulation. The results from the teachers (see below) show their SS, ML MC.

**Figure 1: Teaching Triad, Jaworski, B. (1992)**

The prison education center is where two cultures collide, the culture of the classroom and the prison (Wright, 2005). There has been very little research on the everyday experience of prison education internationally, so we decided to gather data on the practices and rationale. We built this study on previous studies of mathematics teachers, in Ireland, Finland and Switzerland. O'Meara & Prendergast (2018) investigated the length of mathematics classes and the impact on teacher satisfaction. Oksanen & Hannula (2013) used metaphor to explore mathematics teachers' beliefs about their profession and Beeli-Zimmermann (2014) explored adult numeracy teachers' beliefs.

We distributed the survey by email after a discussion with each teacher. During the call, the rationale for the study was given and the invitation was issued to take part. All who were contacted responded. We will extend the study nationwide in future.

The questions are divided into two types; quantitative information on the class structure and allocation and qualitative questions on the teachers' identity using metaphor (Table 1).

1	How long are mathematics classes in your center?
2	How often can people attend mathematics?
3	How satisfied are you with this?
4	How many students are in your mathematics classes
5	Are students of similar or mixed ability?
6	Do you like teaching mathematics?
7	What metaphor describes you as a mathematics teacher?
8	Please explain

**Table 1: The survey for prison mathematics teachers**

The O'Meara & Prendergast (2018) study is interesting because it showed that mathematics teachers in secondary schools were more satisfied with longer and more frequent mathematics classes. Classes in prison are longer so we wanted to investigate the impact of the longer class time on the satisfaction of prison mathematics teachers. Teachers' beliefs can shape their actions, and this could have an effect in prison education, where teachers' values may differ from the prison culture (Wright, 2005). So, we decided to evaluate how mathematics teachers in prison felt about their work as this can impact on their teaching Beswick (2011). We are interested in doing this research because there is a lack of research in the field of prison mathematics education. After teaching for many years in this sector, I felt it was timely to investigate it.

### **What am I doing?**

So, we developed a survey for teachers of mathematics in prison center, based on other studies and issued it to a pilot group of mathematics in prison. We intend to involve a wider group in future. The survey has quantitative and qualitative parts: the quantitative part investigates the timetabling, the composition and the access to mathematics classes. The qualitative part used metaphor to assess teachers' identity and feelings about their work through metaphor. We will analyze this data using a framework such as Linguistic Metaphor Identification (Steen 2010). This was originally planned as an online survey, but these can be problematic in the prison context, so we simplified it and used email. Five emails were sent and five responded.

There is a small number of responses for several reasons. There is a small number of mathematics teachers in the Irish prison education system. There are 13 centers in total and all have at least one teacher, either part time or full time. This data will be part of the next stage in this study. It is a subject with relatively low participation rates, which will be investigated in the next stage of the research. This is the first stage of the research and in the next stage, further data will be gathered from the remaining mathematics teachers in Irish prisons. The final stage of the project will consist of surveying the students attending mathematics classes in prison.

There is often conflict over mathematics, mathematics or numeracy (Kaye, 2015) and the discussion is beyond the scope of this paper. This paper uses the term mathematics, as that is the term used widely in prison education by teachers and students.

The research questions in this study are:

- (1) Are long mathematics classes common practice in Irish prison education centers and how often can students attend?
- (2) Is there a link between teachers' level of satisfaction to the availability of mathematics classes?
- (3) How do Irish mathematics teachers in prison see their identity?

## Results

The quantitative data was analyzed using Excel. Teachers surveyed stated that their mathematics classes varied between 1.5 and 2 hours long (Figure 2). They also stated that students could enrol in as many classes as they wished each week. All teachers stated that they were satisfied with this.

**Figure 2: Hours available for Mathematics classes in prison education centers daily**

We found that mathematics classes in prison were longer, at least one hour (Figure 2). Students could come more often if they wished; all levels and abilities attend at the same time, so students could join classes with people they choose to learn with.

**Figure 3: Maximum numbers attending mathematics classes in prisons surveyed**

In Figure 3, the numbers attending range from 1 to 10 and one respondent was unhappy with the low numbers. 10 is the maximum number in any class according to the respondents.

Students worked individually within the group as all were at different levels and the teachers respected and protected their privacy. This mixture in the class was a challenge at times and took a toll on teachers, in terms of emotional and physical energy, according to some respondents.

A challenge that teachers felt in this context was getting more students to class, as they knew there were many who were not coming to school or who were in other classes but had not enrolled in mathematics yet. They also felt that the students were anxious at the beginning so had to work individually rather than in groups as at the start, they were afraid to let others see where they were at. Some teachers were the only mathematics teacher in their center, some were part of a team in their center.

In response to the question “Are students of mixed ability?” all teachers stated that all students are mixed level. Teachers were asked: “Do you like teaching mathematics in prison?”

Those surveyed all said they enjoyed teaching mathematics in prison and seeing their students grow in confidence and in skills. Teachers stated:

“I enjoy it”

“I love it”

“I like it”

“Yes, I love teaching mathematics ...to see a student’s absolute pleasure at reaching their target.”

Responses to the question “What metaphor describes you as a mathematics teacher?” ranged from “bit of everything” (2 responses) to “facilitator”, “member of a band” and “jazz musician” and “juggler” and “bridge builder” and “breaking down barriers”. Teachers stated that they wanted to ensure students had a positive experience and would return to mathematics class the next day, so adapted their behavior according to the needs of the students during each class. These teachers see themselves in different ways, as facilitators of the group, as led by the group and as a mixture of both. Oksanen & Hannula (2013) stated that in their findings teachers saw themselves in five categories: subject specialist, pedagogue, didactics expert, self-referential and contextual metaphors. We will develop our coding into categories in the future wider study.

As part of my own reflective practice, I picked a metaphor which I felt represented my work as a teacher of mathematics in prison. I feel that I am a tightrope walker, balancing on a fine line in class between challenging my students with mathematics, being sensitive to them and managing the learning while keeping an eye out for risks.

## Discussion

There were many findings from this initial stage of gathering the research. Looking at the data from teachers, they had long mathematics classes of and mixed levels and were generally satisfied with the amount of time students could access classes. They were concerned that so few came to mathematics class. Teachers showed flexibility of approach in their use of words related to their management of learning, such as juggle, rotate, flexibility. Their actions showed a tolerance and

acceptance of where the students were at. The irregular attendance, mixed ability groups, different groups, different class lengths, and frequent breaks during class allowed the students to feel comfortable and enjoy being mathematics class. These factors presented a challenge to teachers at times. Teachers showed an awareness of the role of emotions in mathematics class and noted that they allowed respect and privacy to students, offered individualized teaching within the group. They saw their role as breaking down barriers around learning mathematics and acknowledged that learning is challenging. Teachers expressed their pleasure at seeing student reach their target and acknowledged the difficulties they had in their mathematics learning histories.

*This work draws on the Programme for the International Assessment of Adult Competencies (PIAAC) survey. Last year a first review was conducted on the PIAAC Numeracy Framework (Tout. et al., 2017). In 2018 and 2019 the framework for the second cycle of PIAAC will be developed. This second cycle of the PIAAC survey aims to update the data about the numeracy skills of adults in different countries around the World (Hoogland, Díez-Palomar, Maguire, 2019). The objective of this paper is to highlight some relevant findings from literature on the concept numeracy in order to discuss a potential enrichment of the PIAAC Numeracy Assessment Framework (NAF).*

*Keywords: Numeracy, assessment, adult learning.*

## Introduction

We are now well into the 21<sup>st</sup> century, and lifelong learning is becoming a crucial feature in adults' lives, especially in terms of numeracy, because of the need to live in an increasingly globalized world characterized by rapid technological and economic change. There are major societal and policy pressures on education to prepare citizens for a complex and technologized society (Hoogland, Díez-Palomar, & Vliegthart, 2018; Voogt & Roblin, 2012). What is expected from numeracy education in the current situation? New means of communication and types of services have changed the way individuals interact with governments, institutions, services and each other, and social and economic transformations have, in turn, changed the nature of the demand for skills as well. Globally, too many adults and young people lack the necessary numeracy competencies to participate autonomously and effectively in our technologized and number-drenched society. As a consequence, many people are disadvantaged in terms of employment and face preventable challenges in relation to social well-being and financial security. The results of the last PIAAC survey (OECD, 2016) show that a quarter of the participating countries in PIAAC have numeracy outcomes below level 2 of the 6-point scale. These outcomes give rise to serious cause for concern for the future economic development for many nations. This is an even more pressing issue since the amount of mathematical data that needs to be interpreted and used is increasing rapidly due to technological developments and the emergence of (big) data. However, numeracy is a complex notion that entails different components (Geiger, Goos & Forgasz, 2015). More than a decade ago (in 2003), several scholars meeting in Strobl discussed, during an ALM (Adults Learning Mathematics) conference, the meaning of numeracy versus mathematical literacy (Maasz & Schloeglmann, 2003). It was not clear whether numeracy was just referring to the ability to use mathematics in different situations, or something wider that we can call "mathematics literacy." In this paper we adopt the definition of numeracy developed for the first cycle of the PIAAC survey as

starting point, to discuss the concept of “numeracy” seeking to identify what numeracy concepts are, so a meaningful assessment framework can be developed to recognize these concepts. We will discuss the notion numeracy in order to enrich the basis to develop the NAF that will be used in the second cycle of the PIAAC survey. We draw in a literature review exploring different concepts of numeracy, putting the emphasis on its components. In the next section we present the methodology used to conduct the review discussed in this paper. Then, we introduce the main findings.

## Methodology

In order to answer the research question mentioned above, we conducted a literature review on the concept numeracy. Typically, a literature review is used to frame the problem presented in the introduction of the study (Creswell, 2003). In our case, we are using the literature review as a research instrument to identify relevant literature in order to discuss the different definitions about numeracy. According to Creswell (2003), the first step of doing a literature review is identifying “key works useful in locating materials” (p. 34) that may be relevant for the purposes of the study. In our review we elaborated on past finding by cross-referencing the concept numeracy with a number of reoccurring concepts in the discussions on numeracy. These concepts are: big mathematics ideas, number sense, embeddedness, and authenticity. We decided using those categories since they emerge from the first cycle of PIAAC. We have carried out a documental analysis of articles published in scientific journals included in the main databases and repositories, including the Web of Science, Scopus, for relevant journal articles, and ERIC Database for scholar documents and reports. Additionally, Google Scholar was used to identify potentially relevant literature, that we have subsequently contrasted with the Web of Science and, especially, with the Journal Citations Report database. We used the mentioned categories above as keywords to conduct the searches.

## Results

Following Creswell (2003) recommendation, we present the global results of the review for each of the selected concepts. We also use what Creswell calls a literature map to illustrate the different components regarding to numeracy found in the literature review. Drawing mainly on the documents produced by the OECD (PIAAC, etc.), we created a first approach to the concept of numeracy, using a web-based software to count the number of times (frequency) that each word is used. This provided a first view of the concept of numeracy and how it is being used (Figure 1).

Figure 1: Word cloud of terms related to numeracy (based on OECD documents)

We can see that the word “numeracy” is usually connected to concepts such as mathematics, skills, literacy, education, teaching, workplace, use, work, and data (see Figure 1). However, this first approach is based in a limited exploration. For this reason, we conducted a more fine-grained analysis, using a purposeful procedure (Creswell, 2003) using the three key words, as cited above, in the methodological section. As we can see in Figure 2, those three keywords provided a conceptual network in which aspects such as competence, access, use and interpret mathematics, embeddedness and social practice, invisibility, authenticity, workplace, powerful mathematical ideas, appears interconnected.

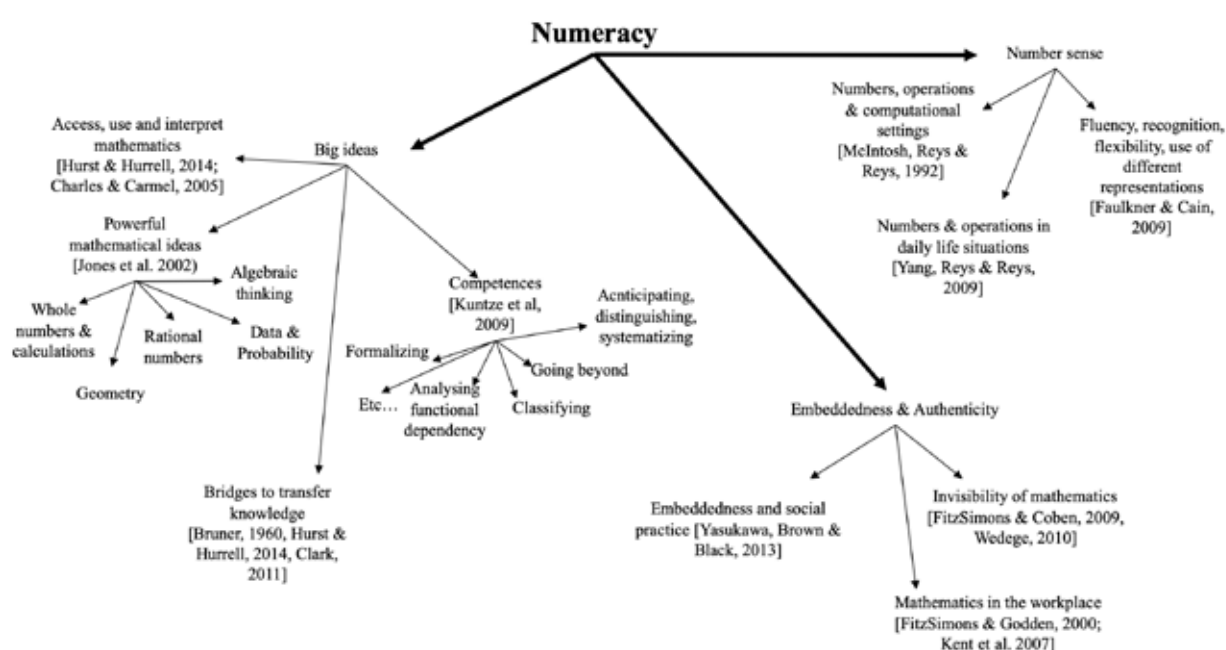

Figure 2: Literature map about the notion of numeracy

## Numeracy and big ideas in mathematics

An entry point to identify relevant schemes, models or instruments to establish the basis of the new numeracy components is the so-called “big ideas in mathematics.” This is a well-known research domain in mathematics education (Jones et al. 2002). There is a general agreement that mathematics proficiency means noticing connections among different mathematics’ concepts and competence in using them. After many decades of mathematics education as a sort of utilitarian discipline looking for ways and strategies for children to perform calculations and solve problems, the vast majority of the mathematics education researchers defend a more relational focused approach to teach and learn mathematics. Jones and his colleagues (2002) provide a great summary of the main contributions of the research to what they call “powerful mathematical ideas”, including the following domains: whole number and operations, rational numbers, geometry, probability, data exploration and algebraic thinking and other underrepresented

domains. It could be argued that being numerated means using the contents of all these domains not just as procedures (instrumental understanding in Skemp's terms) but in a critical / meaningful manner.

In a more recent article, Hurst and Hurrell (2014), quoting Charles and Carmel (2005), state that "big ideas" allow us to see mathematics as a coherent set of ideas, encouraging a deep understanding of mathematics. It could be suggested that being numerate as defined within the PIAAC NAF may link to the idea of being able to access, use, interpret and communicate mathematical information around what the international scientific community calls "big ideas in mathematics." Although it seems that everyone might understand what "big ideas in mathematics" encompasses, the reality is that the construct remains contentious. Kuntze and his colleagues (2011) mention a plethora of different terms referring to the area of big ideas, e.g. fundamental ideas (Schweiger, 2006), central ideas or universal ideas (Schreiber, 1983), core ideas (Gallin & Ruf, 1993), leading ideas (Vollrath, 1978), basic ideas and basic conceptions (Hofe, 1995).

Charles and Carmel (2005) define "big idea" as "a statement of an idea that is central to the learning of mathematics, one that links numerous mathematical understandings into a coherent whole." This definition is also shared by other authors such as Hurst and Hurrell (2014). In their article, they track the notion of "big idea" back to the work of Bruner (1960), who inspired Clark's (2011) definition of big idea as a "cognitive file folder" that we can file with "an almost limitless amount of information." (Clark, 2011, p. 32). Big ideas became conceptual structures (schema in Skemp's terms) that we can use to provide a NAF where content might be characterized by multiple connections. As Bruner (1960), Hurst and Hurrell (2014), Clark (2011) and other authors claim, big ideas may become bridges for the transfer of learning. Drawing on their thoughts, we suggest here using big ideas in mathematics as a skeleton for developing PIAAC NAF.

## Numeracy and number sense

Number sense appears to be one of the main components of "numeracy." Being numerate means having a certain sense of numbers and how we use them to represent, inform, predict, estimate the reality.

McIntosh, Reys and Reys (1992) develop a framework for number sense including three components: numbers, operations and computational settings, which are interconnected. According to them, number sense involves being able to use numbers, operations and their applications in different computational settings. They talk about the meaningful understanding the Hindu-Arabic number system, the development of a sense of orderliness of the number, the multiple representations for numbers (including the idea of composition / decomposition), the understanding of mathematical properties, and the relationship between operations. For them, having "number sense" means being able to solve problems in the real world, providing suitable answers, using (or creating) effective strategies to compute, count, etc. It is not just reproducing instrumentally a certain algorithm but being able to use the mathematical knowledge and components in a flexible manner.

Yang, Reys and Reys (2009) define number sense as "a person's general understanding of numbers and operations and the ability to handle daily life situations that include numbers. This ability is used to develop flexible and efficient strategies (including mental computation and estimation) to

handle numerical problems.” (Yang, Reys & Reys, 2009, p. 384). Regarding the components of number sense, these authors argue “Number sense is a complex process involving many different components of numbers, operations, and their relationships.” (Yang, Reys & Reys, 2009, p. 384). Among these processes, they highlight two aspects, (1) the use of benchmarks in recognizing the magnitude of numbers, and (2) the knowledge on the relative effects of an operation on various numbers.

Faulkner and Cain (2009) claim that “the characteristics of good number sense include: (a) fluency in estimating and judging magnitude, (b) ability to recognize unreasonable results, (c) flexibility when mentally computing, (d) ability to move among different representations and to use the most appropriate representations” (p. 25). The main components of their approach to number sense are: quantity and magnitude, numeration, equality, base ten, form of a number, proportional reasoning, algebraic and geometric thinking.

### **Numeracy, embeddedness and authenticity**

The concept of embedded mathematics emerges primarily from studies related to mathematics in the workplace but also has significance in the broader notion of numeracy. The embeddedness of mathematics refers to a deep connection to the context in which it is utilized. This can mean that the way mathematics is used to operate on a task is fundamentally shaped by the context in which it is employed. This includes socio-cultural influences that afford or constrain action in school, civic, personal or workplace environments. In this view there is a clear separation between school mathematical knowledge, how it is taught, learnt and practiced, and the use of this knowledge outside of schooling. As Harris (1991) notes:

In work [. . .] mathematical activity arises from within practical tasks, often from the spoken instruction of a supervisor and always for an obvious purpose which has nothing to do with the numbers working out well. Thus, students taught to react to isolated, abstract and written commands in the specialist language and carefully controlled figures of a school mathematics class, find themselves confronted with the urgent spoken, if not shouted, instructions in a completely different context and code (p. 138).

Yasukawa, Brown and Black (2013) make a clear connection between embeddedness and social practice arguing that numeracy practices cannot be understood independently of the social, cultural, historical and political contexts. They illustrate this point, they compare students completing calculations individually, using paper and pen and perhaps a calculator against the use of mathematics in the supermarket, in which the same calculations completed at a checkout counter by the shop assistant using a cash register. In this situation the shopper might perform an estimation to avoid being overcharged. However, the shop assistant is equally concerned with charging the customer the correct price and recording accurate record of the items sold via the cash register. The calculations are the same but the purpose – which is related to context - is different.

Embeddedness has led some researchers to talk about the invisibility of mathematics within work or social contexts. This means that mathematics can be fundamental to activities that are not obviously mathematical (FitzSimons & Coben, 2009). This is most clearly apparent in the use of technology in the workplace where digital tools used to complete tasks often obscure underpinning

mathematical activity. As Kent, Noss, Guile, Hoyles and Bakker (2007) argue, within techno-mathematical situations in workplaces there is a shift from ‘fluency in doing explicit pen and paper mathematical procedures to a fluency with using and interpreting output from IT systems and software, and the mathematical models deployed within them’ (p. 2-3).

Building on this point, Wedege (2010) defines two forms of invisible mathematics as (a) subjectively invisible mathematics where people do not recognize the mathematics that they do as mathematics and (b) objectively invisible mathematics in which mathematics is hidden in technology.

## Discussion

Drawing on the contributions coming from the literature review, some considerations emerge.

First, big ideas in mathematics, number sense, embeddedness, and authenticity are important concepts in trying to define the notion of numeracy in the context of the 21<sup>st</sup> century. The *Numeracy Expert Group* working at the PIAAC survey defined numeracy as “ability to access, use, interpret and communicate mathematical information and ideas” (PIAAC Numeracy Expert Group, 2009, p. 21). However, this definition does not provide clues about what “mathematical information and ideas” means. This is a relevant topic, since in the 21<sup>st</sup> century the “mathematics” that may be relevant for adults probably include some of the components highlighted by the scholars working around the notion of big ideas of mathematics. This is also interlinked to the notion of authenticity, since relevant mathematics, perhaps, must to be also authentic (or they are relevant because they are also authentic). If we want to create a new framework for numeracy assessment, then probably we need to look for the mathematics embedded in real situations and draw on them in order to be able to measure adults’ numeracy.

Second, more research is required to identify other important elements of numeracy, especially in the current context of the 21<sup>st</sup> century and the “new” skills that adults must to develop. In fact, numeracy capability is increasingly vital in a world characterized by rapid technological and economic change.

Third, numeracy is vital for social well-being, financial security and informed citizenship. Hence, a framework to assess numeracy must explore how this notion is embedded in authentic practices related with those societal dimensions mentioned above.

Fourth, the critical aspect of numeracy, (not discussed here) related to making evidenced based judgements and decisions, is an aspect of numeracy that has often been underplayed for adults but is an essential element for informed participation in personal, civic and work life. More work is needed in identifying how to promote this critical capability.

Fifth, evidence suggest that adult numeracy has been limited to studies in context (workplace, personal settings or activities, such as shopping, etc.). However, there is a lack of research in terms of cognitive, epistemological considerations of how adults learn/ use mathematics (numeracy skills), which means that additional research is needed to cover those aspects.

# Mathematics and Physics Dialogic Gatherings: Fostering Critical Thinking Among Adult Learners

Javier Díez-Palomar<sup>1</sup> and Evgenia Anagnostopoulou<sup>2</sup>

<sup>1</sup>University of Barcelona, Faculty of Education, Barcelona, Spain; [jdiezpalomar@ub.edu](mailto:jdiezpalomar@ub.edu)

<sup>2</sup>University of Sussex, Brighton, UK; [ea434@sussex.ac.uk](mailto:ea434@sussex.ac.uk)

*This paper discusses the effectiveness of dialogic learning as an adults' learning theory. It specifically focuses on how Mathematics and Physics Dialogic Gatherings (M&PDG) can enhance the critical thinking of adult learners and hence develop their learning in both topics. Two studies were set where the participants engaged in dialogic reading activity reading classics in mathematics or physics. The former study took place in Barcelona, Spain and involved adult women of above 40-years-old with low literacy skills engaging in mathematics. The latter took place in Kendal, UK and involved two groups of adult A Level students, one studying Psychology and the other Physics. Although the samples were extremely diverse, the results demonstrated that classical readings can significantly improve critical thinking and dialogic talk in all groups and provide the potential to create further learning opportunities.*

**Keywords:** Dialogic learning, adult scientific literacy, gatherings.

## Introduction

Dialogic learning has been one of the main approaches to adults' learning theories in the last decades (Flecha, 2000). This approach suggests that adults are self-responsible of their own learning. They become active agents, creating social spaces for learning, drawing on solidarity and social interactions. In order for adults to be active in their learning and express themselves, they must use processes that promote their way of thinking, understanding and their ability to reason; in other words, they must develop their critical thinking (as defined by the Foundation for Critical Thinking, 2017). The aim of this paper is to discuss Mathematics and Physics Dialogic Gatherings (M&PDG) as learning spaces for adults to develop their learning in both topics. Dialogic gatherings were originally implemented by Flecha in La Verneda Adult School, in Barcelona, in the late 1970s. In 1978, a group of people asked for popular education for adults and occupied a public building to offer literacy courses for adults who never had the opportunity to attend school. Drawing on Freire's work (who also visited the school several times), the adults participating in La Verneda Adult School created a democratic popular movement of education based on the principles of dialogic learning (Flecha, 2000). M&PDG are part of this initiative (Díez-Palomar & Cabré 2015, Díez-Palomar, 2017). In the following sections, we will introduce the theoretical framework, the methods used in the research reported here, and the main findings, for further discussion.

## Theoretical framework

According to Flecha (2000), learning is framed by seven principles: egalitarian dialogue, cultural intelligence, solidarity, transformation, the creation of meaning, instrumental dimension of learning, and equality of the differences. Dialogic gatherings are spaces where all these seven principles are evident. Flecha coined the term "dialogic literary gatherings" (DLG) in the late 1970s. He created the first DLG in Barcelona, with a group of non-academic women, most of them barely literate,

drawing on debates between some of the most outstanding scholars in adult education and social sciences at that moment, such as Freire or Habermas. Freire (1970) believed that learning matters because individuals discover that through learning they can make and remake themselves because they realize that they are beings capable of knowing. Learning for individuals is a practice of freedom. We can resist oppression and transform situations of domination, such as the lack of schooling, for example. Habermas (2001) also assumed understanding as a universal ability of human beings. In his *Pragmatics of Social Interaction*, he claims that meaning and understanding are two categories eminently human. Individuals develop their understanding through social interaction, sharing repertoires of meaning embedded in particular actions denoted by linguistic or semiotic signs (Habermas, 2001). Drawing on this idea, Flecha (2000) states that all individuals may be able to develop understanding (learn) using social interaction as a form of scaffolding. The DLG is defined as learning spaces where a) adult learners with low literacy skills participate, b) the readings are universal literature classics, and c) the process is based on dialogic learning (Puigvert, Sordé, & Soler, 2000). The DLG become spaces where individuals participate, interact, and share meanings around particular readings / words/concepts. The DLG became one of the successful educational actions validated in the research project *INCLUD-ED. Strategies for inclusion and social cohesion from education in Europe* (2006-2011).

Drawing on this background, La Verneda Adult School developed the Mathematics Dialogic Gatherings (MDG) using classic readings in mathematics to conduct the gatherings (Díez-Palomar, 2017). The research discussed in this paper starts with this experience and extends the MDG to science (Physics). The second author of this paper used this approach to create PDG in the UK, drawing on the principles of DLG (Soler, 2004, 2016).

## **Methodology**

### **The research question**

In this paper, we discuss some of the main findings from two independent studies focused in the same research question: “Can mathematics and physics classical readings promote the development of critical thinking of adult learners?”.

### **The setting and participants**

The first study reported in this paper was held in Barcelona (Spain). The setting for the study was an adult school placed in a working-class neighbourhood in Barcelona, Spain. Data was collected from May to June 2016 (seven sessions). Participants included six women between 40-years-old and over seventy-years-old, with low literacy skills. The second study discussed in this paper was conducted in Kendal College, Cumbria, in the United Kingdom. Data was collected during the last semester of the academic year 2016-2017. It involved two groups of A Level students, male and female: group PSY, who studied psychology and group PHY, who studied physics.

### **Research design**

In both studies, we created Dialogic Gatherings. These gatherings are spaces in which participants engage in dialogic reading activity involving classic texts in mathematics or science. Participants are the ones choosing the readings. The book selected for the first study was *Historia de las matemáticas*, the Spanish translation Jean-Paul Collette (1979) book *Histoire des Mathématiques*.

For the second study, the reading selected was *Dialogue Concerning the Two Chief World Systems*, by Galileo Galilei (1632). In both cases, we used the methodology of the DLG created by Flecha (see Figure 1).

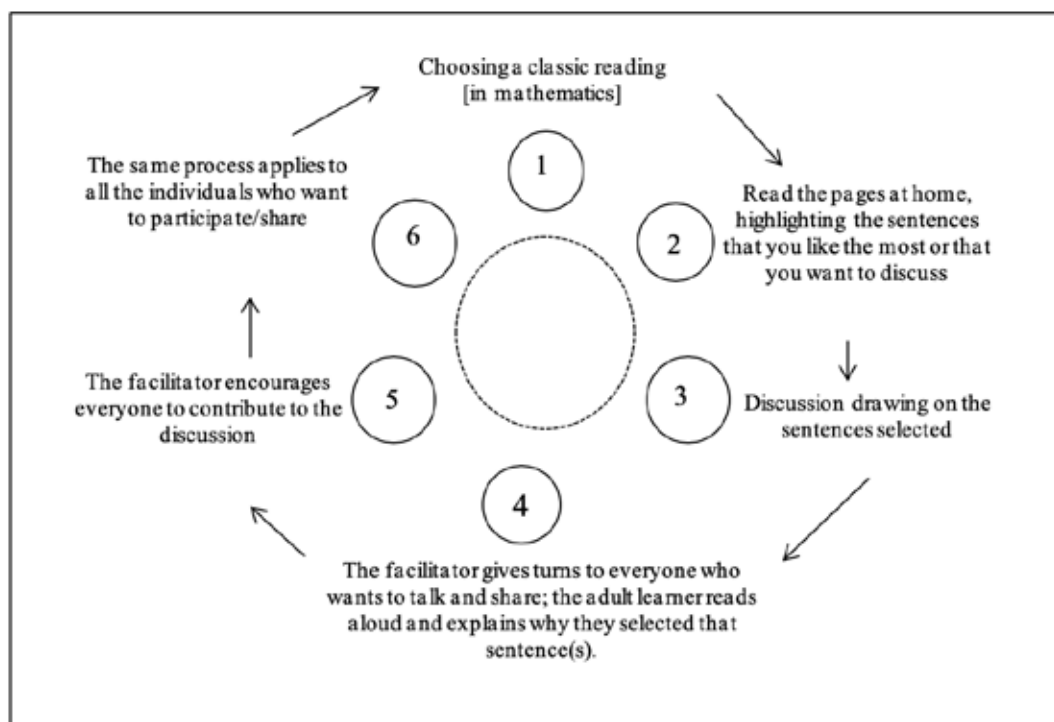

Figure 1. Scheme of how a M&PDG works (Díez-Palomar, 2017)

## Results

The participants in the Mathematics Dialogic Gatherings (MDG) engaged from the very beginning in mathematical discussions around the history of mathematics. The six women seemed comfortable talking about the first traces of mathematics in the Palaeolithic Era, the mathematics used by the Babylonians, the contributions made by the people living in ancient Egypt, the mathematics formalized by the Greeks, etc. Drawing on the description of how humankind developed counting, grouping and the idea of number as the strategy to keep track of cattle, crop, the six women discussed such notions as number system, algorithm, unit of measure, value, equivalence, and so forth. They related some of these concepts with their everyday life. For instance, when discussing the concept of the base of a number system, they rooted their arguments in their previous knowledge about using different coins whose value is defined by groupings in base 1, 5 or 10. Their knowledge about *duros* (a coin equivalent to 5 pesetas in the old Spanish currency) facilitated their understanding about ancient number systems which a base different from the Hindu Arabic numbers that we use nowadays. Jean-Paul Collette mentions in the first chapter of his book that a bone was found in the Czech Republic with some tally marks carved in groups of approximately 30. According to the experts, it could be a moon calendar. Interestingly, one of the women in the group highlighted this excerpt of the book because she stated: "I remember that I read somewhere that some people think that those marks correspond to the menstruation cycle." Then, a further discussion about mathematics and human biology started, connecting mathematics to gender issues. During the sessions, many other issues arose: Why the Romans didn't have the zero in their number

system?, How to translate quantity from one unit of measure to another?, and What strategies are best in problem solving?

For every topic, the participants in the MDG used their own personal background to, in Flecha's (2000) terms, "create meaning with the mathematical content. The book presented many symbols and codes (numerals, formulas, graphical and visual representations), that usually are abstract representations of real phenomena. Data suggest that women were able to create a zone of proximal development where everyone was free to contribute with their piece of knowledge drawing on their own experiences. According to Hutchins (2000) this can be defined as episodes of distributed cognition. That was the case when developing an understanding an ancient algorithm for multiplication presented by Jean-Paul Collette (1985) in his book.

In the same vein, the Physics Dialogic Gatherings project further examined participants' progress with respect to their background knowledge, in a different setting.

During the first sessions, the psychology group got involved in discussions in a descriptive and philosophical manner. They felt more confident to discuss philosophical ideas, such as the definition of *perfection* in the text, and they tend to avoid or ignore any scientific or mathematical part of the book. An example from a participant:

"If I were in this conversation I would question the definition of perfect and what is exactly they are trying to achieve by defining these principles? What are they going to achieve if they finally define that the Earth is perfect? What does perfect mean?"

They often exchanged information directly quoting from the text without showing any understanding of the ideas transmitted. For example:

"Pythagoras says it's defined by beginning, middle and end, but others are saying perfect is how you form the body; the length, and thickness."

They did not challenge the obvious. They preferred to agree with that. Direct quotation from the text:

"They say about the lines that the straight line is the shorter one and obviously you can have many other lines. I agree with that."

During the later sessions, they felt confident to discuss science too, starting with simple arguments and poor terminology. Their dialogic skills evolved with time when they felt the need to use definitions and self-created terminology. They created their own terms when the lack of scientific knowledge did not help.

"I think it depends what fast is. In our situation our fast is like steady and we have air-resistance and when it reaches terminal velocity, it will be like balanced. Whereas if you are in a car and it speeds up and in fact you are in control of the fastness, you will just accelerate until you reach where you want to go and then you will put another force acting into it because you want to slow it down. So it depends on which fast it is acting on."

They could formulate arguments where critical thinking was evident. As they were feeling more comfortable, they progressed to using scientific terminology, which emerged either from the text or

from prior knowledge that they had not used for a long time, but they recovered it for the sake of their argument.

“So, say you have a forward motion, velocity and then you have the air resistance and gravity. They would balance out in a way that the one motion is still more than the others because it still moving forward, because if the others weren’t there it wouldn’t have to speed up.”

Their critical thinking was developing, and they were more involved in discussing their ideas in a dialogic manner, even if these ideas could be wrong.

“If the plane is tilted, the ball starts moving and speeds up until it reaches towards the end. And then reaches a flat surface again. So yes, I agree with that. There has to be some kind of limit, because... I don’t know... It can’t just speed up, speed up, speed up. It has to be some kind of limit.”

Towards the final sessions, they were able to combine physics and philosophy into their arguments, which triggered further discussions and carried forward their learning skills.

“It’s got to have some purpose to move. A body which is not moving, will move if it has a purpose.”

The physics group seemed more open to disputes and reasoning than the psychology group, possibly because they considered the text to be more on their area of expertise. They approached the ideas presented with scepticism and doubt, rather than with unquestioning acceptance, which already indicates a level of critical thinking (Scriven, 1987). In the early sessions, the group was dealing with the texts purely scientifically, ignoring any philosophical quotations in contrast to the psychology group. The physics group was seeking for proofs and they even performed their own in-class short experiments to prove a point.

“Salviati is saying that he doesn’t believe that 3 is necessarily more perfect than 4 or 2, and gives the example of legs on a chair or table. And I was wondering if it is harder to knock over a table with 3 legs or 4 legs, because with 2 legs obviously it is not stable.”

They employed their scientific background knowledge to explain the ideas presented in the reading.

“Triangle is the strongest shape in nature so I guess it may be stronger.”

“...because there are more ways where you can pass the center of gravity.”

At later sessions, the group was involved in philosophical critical thinking too. The engagement with the philosophical terms expanded their discussion away from the actual text and they were able to connect science with philosophy. Their critical thinking and dialogic talk development evolved to a point where they were disputing scientific methods that they had never disputed before. They questioned science and mathematics and they concluded that they had more trust in their senses than some scientific proofs.

“Does mathematics support or help science, do you believe things because you see them to be mathematically true or do you believe things because you see them to be physically true? What creates new knowledge?”

## Discussion

In 1976 Wood and his colleagues coined the term “scaffolding” as a metaphor to analyse how adults assist children when solving problems. They defined it as an action that “enables a child or novice to solve a problem, carry out a task or achieve a goal which would be beyond his unassisted efforts” (Wood et al, 1976, p. 90). This concept moved forward the old Vygotskian notion of ZPD (Bruner, 1986). Cazden (1979) extended the concept from its original use in the context of dyadic adult-child interactions, to a study of teacher-student interactions in classroom settings. More recently, a special issue published in 2015 in the journal *ZDM Mathematics Education* (47,7) explored the interlink between this metaphor and the idea of dialogic teaching. Evidence suggest that dialogic teaching pushes forward to notion of scaffolding, since *dialogue* creates opportunities for participants to exchange and share knowledge from which create their own understandings. In this paper, we found evidence suggesting that this approach can also be used in the context of adults learning in both mathematics and physics.

Overall, the Mathematics and Physics Dialogic Gatherings project proved to be an enjoyable method for the teaching and learning of physics and mathematics. Data collected suggest that egalitarian dialogue can create opportunities for learning. The participants, drawing on their dialogic talk, created Vygotsky’s (1978) zones of proximal development where all participants contribute with their cognitive potential. Our results also confirm Hutchins’ (2000) notion of distributed cognition, since many times the different participants ended with a complete explanation of a particular notion, such as the uses of the zero in a number system, after sharing different pieces among them. The egalitarian dialogue, as defined by Flecha (2000), means that everyone has the same opportunity to share his/her previous knowledge throughout a dialogic process in which every participant shares arguments based on valid claims. The participants of the psychology and the physics groups as well as the mathematics group were able to make valid claims on the understanding of mathematical, scientific and philosophical concepts. This suggests that the critical thinking of both groups was significantly improved.

In addition, the results also reveal that using an egalitarian dialogue based on personal previous knowledge, adults were, in Freire’s terms, able to *read (and re-read) critically the world*. The different notions discussed during the sessions in both settings gained from this personal way to present them to the audience in the M&PDG. Linking them to personal situations in the everyday life appears to be a successful strategy to create meaning around the concepts discussed in the group. As Flecha (2000) states: “the creation of meaning is one of the more seminal principles of the Dialogic Learning theory since learning is strongly connected to motivation, as previous studies have largely demonstrated (Mehler & Bever, 1967)”. Freire narrates the case of a woman who learned to read and write by sending love letters to her husband. For this woman, the words acquired full meaning because they transmitted her feelings to her husband, who was far away. In a similar vein, for the women participating in the MDG recalling their memories about duros and pesetas was a way to make meaning to the idea of base in a number system. In this situation, grouping, which is an important component of numbers in number systems (as well as in the development of number sense), was fully understood by the six women participating in the MDG. They not only used the notion of grouping (base); they were also able to explain different algorithms to do mental calculation drawing on the use of grouping as a cognitive strategy to solve

particular cases of calculations (mainly addition and subtraction, and sometimes multiplication as well).

The research demonstrated that background knowledge is important to establish an egalitarian dialogue, in the sense that everyone uses their own repertoire of knowledge to participate in the dialogue. Although the two groups were very diverse in terms of background knowledge, they ended up in parallel ideas when combining mathematics, philosophy, and science. They approached the notions from a different perspective but somehow, they concluded in similar ways. Combining mathematics, science and philosophy opened new perspectives into their learning of physics and mathematics. In fact, results suggest that “heterogeneity” may be a successful component of M&PDGs. Without that heterogeneity, participants in the gatherings would not be able to introduce different examples to illustrate particular scientific or mathematical notions, making learning more depth and meaningful for everyone in the group. The Dialogic Gatherings method can, therefore, benefit heterogeneous groups, where people can learn from each other, taking advantage of the knowledge that everyone shares within the discussion. This is consistent with previous research in the educational arena (Flecha, 2000; Vygotsky, 1978; Wertsch, 1990).

Summarising, evidence suggests that classical readings and egalitarian dialogue could be an excellent method to improve critical thinking in mathematics and physics and have the potential to create further learning opportunities in classrooms.

## **Conclusions and further research**

In this paper, we have discussed how adults in two different settings (Barcelona and Cumbria) draw on their participation in the M&PDGs to develop their critical thinking around mathematics, science, and philosophy. Results suggest that adults use their own personal background to make meaning to the academic concepts in the books selected. Egalitarian dialogue mediates learning through a participatory process in which adults share their personal understanding of the topics discussed in the gathering. They use practical examples, drawing on their memories and looking for plausible explanations. In doing so, they acquire proficiency in using expert scientific and mathematical jargon. However, evidence reported here are limited since they belong to two single case studies. The sample is neither representative nor random. The examples introduced in this paper illustrate some intuitions about how adults, using classic readings in mathematics and science, can further learn and create a critical thinking aligned to what some authorities claim as being critical citizens in the rise of the 21<sup>st</sup> century. However, due to the limitation of the research design, more research is needed in order to generalize the benefits of the MP&DGs in supporting adult learners’ critical thinking, in other settings.

## **Acknowledgment**

The authors want to express their gratitude and acknowledgment to all the adult people participating in the M&PDGs.

# Using dialogue scenes with adult mathematics learners: Research questions and methods

Graham Griffiths

UCL Institute of Education, United Kingdom; [g.griffiths@ucl.ac.uk](mailto:g.griffiths@ucl.ac.uk)

*This paper is an outline of the research questions and methods, informed by an exploratory phase of data collection and some initial observations from the main phase, selected as part of my doctoral studies into adults learning mathematics. The work is an investigation into the discussions which take part during and following a particular small group activity type in which a scene is read aloud and a mathematical task is undertaken. This paper outlines research utilising ‘thinking as communication’ as proposed by Sfard (2008) and employs an overarching framework for analysis developed by Morgan and Sfard (2016). To understand what happens when the ‘reading aloud’ activity is undertaken, it is important to investigate what happens when learners undertake related activities.*

*Keywords: Collaborative discussion, discourse analysis, dialogue, adult education, mathematics.*

## Introduction

This work started with an interest in teaching practices and a wish to investigate, in some detail, the collaborative discussions that occur between learners when undertaking a particular type of activity (Griffiths 2014). From this starting point, my work has become more focused on generating data to inform a theoretical perspective on learner-learner discussions. I am interested in the interactions that occur between learners during the implementation of a form of classroom activity, namely the reading aloud of a scene of dialogue concerning mathematics and a linked, collaborative mathematical task.

## Theoretical perspectives on learning

Dialogue (and conversation) has been seen as a useful focus of attention in the educational world and utilised in a variety of ways. For example, classroom dialogue has been investigated within the framework of dialogic teaching by Alexander (2017) and has resulted in a special edition of ZDM (see Bakker, Smit, & Wegerif (2015)). Much of this work has been interested in the dialogue that occurs between teacher and learner whereas I am interested in learner-learner interactions with minimal input from teachers when undertaking the specified task. Having said this, there are important ideas that are in common to such work and my research. For example, notions such as the importance of sense making and socio-cultural influences on learning involved in such discussions are also important in my work. Such sense making and socio-cultural perspectives draw upon literature that stretches back to writers such as Bakhtin (published in English in Bakhtin 1986), and Vygotsky (published in English in Vygotsky et al. 1978). These writers have also influenced more recent work that I am utilising (in particular Sfard 2008).

Central to my work is the question of whether reading aloud has an effect on the resulting collaborative discussions compared to reading silently. This was initially motivated by my own experience of observing such activity. Nonetheless, there is a question as to what the literature says

about the effects of reading aloud and silently. Much work has already been undertaken into studying the effects of reading aloud compared to reading silently when related to language and the effect on subsequent educational performance. For example, García-Rodicio, Melero & Izquierdo (2018) provide evidence that suggests there is no significant difference in performance between reading aloud and reading silently when dealing with comprehension exercises (in fact, they note that individuals following others reading aloud can result in significantly worse performance on tests). It is worth noting that this type of study takes an acquisitional perspective (in the sense of Sfard 1998) and is concerned with performance on some standardised test. My study has an interest in participation in a given activity type and the evidence in the transcriptions of discussion related to that rather than the effect on some standardised test. As such the perspective taken by García-Rodicio, Melero & Izquierdo (2018) and similar work is not of interest to me. Other work, for example Duncan (2015), has a focus on the perceptions of individuals and their practices related to reading aloud. This work does suggest positive aspects to the practice of reading aloud. Although Duncan's work is not interested in mathematical development, I am more interested in the practice focused work of this type of work.

The theoretical perspective that I intend to use, that of thinking as communication, has been developed in recent years and been given a detailed rationale by Sfard (2008). My research takes the participatory approach of seeing *thinking as communication* that Sfard argues for. Within this perspective, learning is not seen as concerned with changes to some internal schema, that is responding to experiences, but rather the communication itself is viewed as thinking and learning. Sfard argues that the job of the researcher is to investigate communication. The discussions that happen during and following an activity would provide an example of communication which could be investigated and Sfard (2001) proposes a form of discourse analysis and suggest some aspects to look for in such work. In particular, she identifies for analysis the *mediating tools* involved in discourse and a set of *meta-rules* that govern discourse.

For example, the text in the scenes provides an example of a mediating tool. When discussing the scenes and engaging in classroom discourse related to mathematics, it is not surprising to hear direct extracts from a text being used by participants along some paraphrasing of sections. In addition, the mathematical examples used within the text are mirrored back in many cases. Indeed, one of the reasons that Swan (2006) has constructed the scenes (DfES 2005) that initiated my work is for discussion to focus attention on key elements of mathematics. It seemed a reasonable working assumption that by asking learners to read text aloud, it is likely that, at least for some groups and individuals, focus will be put on those words and phrases. Part of my research is investigating this aspect, to see the ways in which specific parts of the text are employed in discussion of the scenes.

The term 'meta-rules' might suggest a strict set of guiding principles while, in reality, this might be less rigid. Indeed, Sfard suggests that there could be a wide range of possibilities for a hypothesis to govern a discussion and such a meta-rule will need to be interpreted from the discourse. As an example, in a discussion of mathematics between two boys, she proposes that one of the contributors is focused on mathematical meaning while the other appears to avoid discussing mathematical ideas while employing, for example, face saving devices (such as humour) which suggest a concern for social position. This can be seen as another, different form of, socio-cultural

issue raised by Lerman (2001) who argued that the role that individuals play and aspect of power and position in society will have an impact on discourse and need to be considered.

Within the discussions that I am concerned with, such meta-rules may be related to resources that the participants utilise other than those in the text (identified as mediating tools). Such additional resources include the use of mathematical discourse that draws upon prior experiences (either within their present educational setting or from an earlier situation) as well as non-mathematical discourse. In the case of our task, which involves a discussion around the price of rail tickets, it is not a surprise to note that participants have contributed with discourse concerning their own use of the rail system (thus introducing an element of socio-cultural influence).

In my research, I use an overarching framework developed by Sfard, Morgan and others (in particular Morgan & Sfard 2016). The framework structures the characteristics of discussions into two main categories for analysis: (a) the mathematising aspects of discourse and (b) the subjectifying aspects of discourse. Further elaboration on this, with examples, is provided below. The reason for selecting this form of analysis is that it is designed to be of interest to mathematics education rather than utilising more general categories that occur with other forms of discourse analysis. The analysis of the collaborative discussions consists of investigating a range of factors and I have been interested in the following sub questions under the two identified categories.

(a) The mathematising aspects of discourse:

- (i) What resources do the individual participants use in the discussions (please note that resources here might mean physical resources such as a calculator but also the examples that are chosen by the participants and the proposed calculations that are employed)?
- (ii) To what extent do these resources relate to the text in the activity (a mediating tool) or draw upon other experiences (and therefore suggest meta-rules are being employed)?

(b) The subjectifying aspects of discourse:

- (i) How do the individual participants contribute to decision making within the group?
- (ii) How is the discussion regulated by the individual participants involved?
- (iii) How do the participants see themselves in relation to mathematics (in general and specific to the activity)?

The specific activity that my work is concerned with consists of a mathematical task along with a scene in which four characters discuss the task (see Figure 1 and Figure 2 for details of the task and activity). The task asks participants to agree or disagree with a given statement related to a percentage problem. The activity of interest involves the learners taking and reading aloud the parts of four characters who argue different positions related to the task. This is then followed by a discussion in which the participants are intended to come to their own conclusion concerning the task.

Task	Scene 1 (as in DfES 2005)	Scene 2 (amended features)
<p><i>Rail Prices</i></p>  <p>In January, fares went up by 20%.</p> <p>In August, they went down by 20%.</p> <p>Sue claims that:</p> <p>“The fares are now back to what they were before the January increase”</p> <p>Do you agree?</p> <p>If not, what has she done wrong?</p>	<p>Harriet: That’s wrong, because ... they went up by 20%, say you had £100 that’s 5, no 10.</p> <p>Andy: Yes, £10 so its 90 quid, no 20% so that’s £80. 20% of 100 is 80, ... no, 20.</p> <p>Harriet: Five twenties are in a hundred.</p> <p>Dan: Say the fare was 100 and it went up by 20%, that’s 120.</p> <p>Sara: Then it went back down, so that’s the same.</p> <p>Harriet: No, because 20% of £120 is more than 20% of £100. It will go down by more so it will be less. Are you with me?</p> <p>Andy: Would it go down by more?</p> <p>Harriet: Yes because 20% of 120 is more than 20% of 100.</p> <p>Andy: What is 20% of 120?</p> <p>Dan: 96...</p> <p>Harriet: It will go down more so it will be less than 100.</p> <p>Dan: It will go down to 96.</p>	<p>Harriet: That’s wrong, because ... they went up by 20%, say you had £100 that’s 5, no 10.</p> <p>Andy: Yes, £10 so its 90 quid, no 20% so that’s £80. 20% of 100 is 80, ... no, 20.</p> <p>Harriet: Five twenties are in a hundred.</p> <p>Dan: Say the fare was 100 and it went up by 20%, that’s 120.</p> <p>Harriet: And, because 20% of £120 is more than 20% of £100. It will go down by more so it will be less.</p> <p>Andy: What is 20% of 120?</p> <p>Dan: 96...</p> <p>Harriet: It will go down more so it will be less than 100.</p> <p>Dan: It will go down to 96.</p> <p>Sara: No, it has gone up £20 to £120 and then it went back down the same, so that’s £100.</p>

Figure 1: The task and scenes 1 and 2.

Activity RAS1&2	Activity RSS1&2	Activity NS
<p>In groups of 4:</p> <p>Choose to read out the parts of:</p> <p>Harriet, Andy, Dan &amp; Sara</p> <p>Then read out the scene and discuss what you think about Sue’s claim that “the fares are now back to what they were”.</p>	<p>Read the scene below</p> <p>In groups of 4:</p> <p>Discuss what you think about Sue’s claim that “the fares are now back to what they were”.</p>	<p>In groups of 4:</p> <p>Read the statement from Sue below.</p> <p>Discuss what you think about Sue’s claim that “the fares are now back to what they were”.</p>
<p>Activity RAS1 is then followed by the Task and Scene 1 from Figure 2 (and similarly for RAS2), Activity RSS1 is then followed by the Task and Scene 1 from Figure 2 (and similarly for RSS2) and Activity NS is followed by the Task only from Figure 2.</p>		

Figure 2: The three activity types

During an exploratory phase, examples of the activities described in Figure 1 and Figure 2 were undertaken and reported on in Griffiths (2014). Examples of discussions were included which showed some different responses to the different activity types. Data taken from this exploratory phase along with early observations from the main phase will be used to illustrate issues in this text.

## Methodology

My study takes a qualitative, inductive approach, using a series of case studies and utilising the theoretical frameworks noted earlier for analysis. The work explores the data that is gathered to see how it fits the proposed framework with an aim of suggesting variables for further study.

The data collected consists of audio recordings and observational notes of learners undertaking the activities along with audio recordings of short focus group discussions (one per cohort) about the process immediately following the activity.

## The research design of the main phase

To identify some characteristics in the response of learners to the activity involving reading aloud, it is helpful to identify what happens when the activity involves reading silently. In addition, the use of the mathematical task without a dialogue scene is used as a way of identifying the extent to which elements of analysis relate to the use of mathematical scenes whether read silently or aloud. A final issue concerns the nature of the scene itself. It is possible that responses may be produced as a result of the particular elements of the text. For example, characters within a text may have more dialogue and thus be given priority, or the first and last statements might have more dominance. In order to take this set of issues into account, alternative versions of the text have been developed and used.

The research design chosen considers 5 activities (see Figure 2) which are used as interventions with additional (to the exploratory phase learners) groups of (four) learners across 4 institutions (giving a total of 20 groups and 80 learners):

RAS1 – activity which involves reading aloud the scene as described by Swan (in DfES 2005)

RAS2 – activity which involves reading aloud an alternative version of the scene

RSS1 – activity which involves reading silently the scene as described by Swan (in DfES 2005)

RSS2 – activity which involves reading silently an alternative version of the scene

NS – activity which involves the task without the scene

To distinguish which characteristics are related to reading aloud, the overarching research question is then refined to become the following question:

*What are the similarities and differences in the characteristics of learner discussions during and following the identified activities?*

The analysis is considered in relation to contextual information, such as participant backgrounds and experiences, that becomes known as the research progresses including information noted when agreeing the groups to be studied with centres, the recording of the discussions that occur while undertaking the full activity and focus group discussions following the activity.

## Observation and discussion

The following text describes some initial thoughts utilising data collected from the exploratory phase along with initial observations from the main data collection without detailed analysis. The first category concerns the nature of the mathematical tasks involved in the research, thereby addressing the mathematising aspects of the activities (and resulting discourse). The second two categories are concerned with the responses of participants to the activities, and with others in a group, thereby addressing issues related to subjectifying aspects of the activities (and discourse).

### **The relationship between mathematics, the context of the activities and the activity types**

The three activity types (RAS, RSS, NS) have one thing in common in that the notion of percentages is linked to rail prices and as such is making links to the ‘everyday’. The task, deciding whether an individual is correct or not, is not necessarily what might be understood as a traditional task, that is, one in which a calculation is undertaken and presented with an answer. In addition, the task, while relating to aspects of real world activity - the buying of tickets, the notion of sales and discount – involves the combination of information that can be seen as somewhat artificial (and perhaps encourage responses involving humour for example in the exploratory phase a contributor suggested that a passenger will be “ripped off”).

In the main phase of data collection, while participants most often use the example of the price given within the scene (that of £100), other examples of mathematising are clear such as the strategies used to calculate 20% which were not evident in the text. From early observations of the main data collection phase, it is not yet clear whether reading aloud or not is significant in relation to this.

### **The relationship between participants and the activity types**

A key aspect to consider is how participants in the activities relate to the information and roles presented in the scene. One example is the scene use of the proposed £100 ticket price. This would suggest the use of rail travel between towns and cities rather than more local commuting. Another example concerns the (assumed) genders of the participants in the scene and the selection of roles for reading aloud. I have seen the choice of character being led by gender on a number of occasions (and discussed in the focus groups).

In the exploratory phase, one contributor talks about ‘they’ (“what they’re saying...”) and another specifically mentions the character Harriet by name. In the main phase, some individuals undertaking RSS noted that they only read the first few lines of the scene. One of the groups selected to read aloud had identified, and agreed, mathematical statements which would lead to them saying Sue was wrong but did not want to commit to this judgement. In another discussion following the non-scene task, participants suggested £5 as a rail ticket. These are examples of subjectifying aspects of the discussion while on some occasions being linked to mathematising aspects such as related calculations.

### **The regulation of discussion**

The utterances that are involved in a discussion will follow some, usually unspoken, set of rules (meta-rules in Sfard’s terms). I have already noted that Sfard (2001) argues that some participants

will have a focus on mathematical meaning while others may focus on alternative, and potentially face saving, aspects of discussion. I draw upon two aspects of discussion that have been written about which can be interpreted as involving subjectifying aspects of discourse, one concerning school discussion, uncertainty and hedging, and another that has been noted in relation to adults and the use of humour.

The significance of uncertainty and signs of hedging in discussions has been noted (in particular Lakoff (1973)). In my exploratory investigation, one participant starts by suggesting that she does not understand what is happening and yet then follows with the mathematically expected responses.

Oughton (2010) has noted the importance of humour in the interactions between learners. She suggests that adults use positive, affiliative humour in group working in order to deal with anxieties that they feel undertaking mathematics. Interestingly, within the exploratory data we see the use of humour to end discussion (“So... you still get ripped off whichever way”). The comment seems to be a mechanism to end the discussion and may be an attempt to disguise uncertainty about meaning.

## Conclusion

Having noted that the study is anchored in practice, the study itself is likely to be of interest to researchers interested in forms of discourse analysis within mathematics education. The study has generated data that is intended to inform a theoretical understanding of the effect of reading aloud on classroom discussion with such mathematical scenes. This detailed analysis is still to be undertaken although observations so far suggest some interesting indicators of what to focus on.

While of primary interest in the research field, it is expected that the study will help to inform classroom teachers of (adult) mathematics classrooms. It is not intended to identify a toolkit that enables teachers to produce their own scenes but rather to identify a potential use of the existing scenes in two main ways:

- a) To propose and describe (including key features) the classroom activity of reading aloud dialogue scenes involving mathematics (not an expectation of the original Swan scene)
- b) To outline what might be expected to happen in the discussions between learners when undertaking the activity

This will then allow teachers to make their own decisions about whether to employ these activities (or perhaps similar ones) with their own learners.

## Acknowledgment

The author thanks the many individuals who have supported this project so far including the staff and learners involved and particularly supervisors Prof. Candia Morgan and Dr. Samantha Duncan.

# Reproducing social difference in the concept of ‘numeracy skills’

Lisanne Heilmann

University of Hamburg, Germany; [Lisanne.heilmann@uni-hamburg.de](mailto:Lisanne.heilmann@uni-hamburg.de)

*This paper is concerned with adult numeracy skills as these are presented within the Programme for the International Assessment of Adult Competencies (PIAAC). It will focus on what we can learn from PIAAC results about adult skills, about the assessment and about societal structures. Theoretical discussions increasingly view numeracy as embedded in power relations. If so, these power relations should be visible in the results. This paper will provide a brief overview of underlying theory in the field, focusing on three elements of numeracy skill proficiency: the distribution of skills in society, the process of defining a hegemonic view of numeracy skills and finally, the value of numeracy skills in the context of power relations. This value of numeracy skills can be analysed by the example of gender relations in the labour market. The analyses will use PIAAC-data to indicate how gendered hegemony might influence the way numeracy skills matter in terms of monthly wages and the probability of getting into leadership positions.*

**Keywords:** Basic skills, gender bias, labour market, adult education, PIAAC.

## Introduction

Educational research often looks at skills as something to acquire. Once acquired, it is anticipated that skills bring benefit to their possessor by transforming skills into success. Following that line of argument, a common aim is to make education available and suitable for more people; assuming, that if education would only find a way to convey knowledge more efficiently, this would bring direct benefit to people in terms of happiness, health, or success in the labour market (Grotlüschen, Mallows, Reder, & Sabatini, 2016; Kittel, 2016; OECD, 2016a). Craig (2018) argued – in a paper called ‘the promises of numeracy’ – that numeracy education is largely associated with empowerment and seen as relevant for social participation, while innumeracy is connected to “personal, social, and cultural costs” (Craig, 2018, p. 64). This paper is a reflection on PIAAC results with this perspective in mind. The OECD assessed via PIAAC the literacy and numeracy skills of 16-65 year-olds. In 2011/12, 24 countries participated in the first round of assessment. Nine other countries followed in a second round in 2014/15 (OECD, 2016a).

There is a variety of definitions and concepts around numeracy, mathematics, quantitative literacy used in international contexts. (e.g. Karaali, Villafane-Hernandez, & Taylor, 2016; Vacher, 2014). For this paper, the terms *numeracy* and *numeracy skills* refer to PIAAC’s definition:

PIAAC defines numeracy as the ability to access, use, interpret and communicate mathematical information and ideas, in order to engage in and manage the mathematical demands of a range of situations in adult life. (OECD, 2012, p. 34)

An alternative view on skills focusses more on their embeddedness in society and in power relations. Being embedded in social constructs means being greatly influenced by power structures. Thus, it is worth asking, whether Craig’s ‘promises’ are equally true for those who acquire them.

Using the example of gender to look at a concrete representation of societal power relations, PIAAC results offer the potential to analyse the intersection of gender and numeracy empirically and with quantitative methods. In this paper, I choose a regression analysis to test the value of numeracy skills in terms of income and the chance of getting into a leadership position. The scope of difference between these values for men and women will also be explored.

## Numeracy in relations of power

### Distributing numeracy

How do people acquire numeracy skills and why do some attain higher skill proficiencies than others? Focusing on gender differences, the achievement of young boys and girls has received much attention for the past decades and continues to be of high importance (OECD, 2016b). Surveys such as PISA<sup>1</sup> and TIMMS<sup>2</sup> test students at the ages of 10 (TIMSS) and 14/15 (TIMSS, PISA). These assessments show that boys tend to perform higher on numerical and science-related tests. The difference is small, but nevertheless significant (Mullis, Martin, Foy, & Hooper, 2016; OECD, 2016b). A comparison between these and further assessments of numeracy and mathematical competencies from the years 1994 to 2007 show that gender differences increase with age and grade. The performance of boy's on numeracy and mathematical proficiency increases from the seventh grade on. The difference between boy's and girl's performance on such assessments can be related to stereotypes and expectancies. Not only do teacher seem to expect and (unconsciously) support different skills and interests of boys and girls, but also, students expectations of themselves have been shown to align with their interests and their self-concept to what they think is expected from them (Budde, 2009).

Regarding the adult population, results from PIAAC show men scoring higher on the numeracy scale than women with the gender gap greater in older age cohorts (OECD, 2016a). The presented findings on young students and adults show differences in how numeracy skills are distributed among genders.

### Determining numeracy

In a comprehensive look at the social aspects of numeracy, Street, Baker and Tomlin (2008) transferred insights from the New Literacy Studies to the field of numeracy and argued that numeracy is a social practice. This idea of a multiple of skill interpretations originates in the New Literacy Studies (Street, 1993). Contemplating the great variety of numerate practices – numeracy itself has to be seen as *multiple numeracies*. The relativity of numeracy is not only evident in the social distribution of skills but also in determining what constitutes as mathematics or as numeracy. As such, all numeracies are embedded in power relations and subject to the societal hegemony. A variety of studies have demonstrated how numeracy skills and practices are embedded in economic outcomes (Grotlüschen et al., 2016) or how values, beliefs and power relations determine the idea and the relevance of numeracy and mathematical education (c.f. Ares & Evans, 2014). The

---

<sup>1</sup> Programme for International Student Assessment (by OECD)

<sup>2</sup> Trends in International Mathematics and Science Study (by IEA, International Association for the Evaluation of Educational Achievement)

relativity of numeracy is not only evident in the social distribution of skills but also in determining what constitutes as mathematics and as numeracy. Different studies showed how skills and practices are embedded in economic outcomes (Grotlüschen et al., 2016) or how values, beliefs and power relations determine the construct of numeracy and mathematical education (Ares & Evans, 2014). Following postmodern theories, some researchers view mathematics and numeracy to as constructed in discourse in every aspect (Ernest, 2004). Velero (2004) suggests this perspective allows us “to perform a very fine grained analysis of how mathematics and mathematics education are used by people in particular discourses and of the effects of those discourses on social practices and, consequently, on people's lives” (p. 11).

## **Rewarding numeracy**

Continuing from the perspective of that power relations shape numeracy conceptualizations and acquisition, the following analyses will show empirically that gender relations affect the value of numeracy skills on the example of labour market outcomes. Regression analyses of PIAAC data will be used to show how numeracy proficiency does not have the same value for everybody. Looking at two labour market outcomes (wages and leading positions), the analyses that follow will reveal how the effect of numeracy skills changes with gender.

## **Method: Data and sample**

The presented research was carried out with PIAAC datasets for 13 European countries. The analysis disregarded those European countries whose PIAAC data did not disclose all variables employed. It therefore includes the following thirteen European countries: Belgium, Czech Republic, Denmark, Spain, Finland, France, Germany, Greece, Ireland, Italy, Netherlands, Norway and Poland.

PIAAC scales its numeracy test items based on item response theory (IRT) to account for differences in item difficulties. Based on the IRT scaling of the items and a population model, plausible values are drawn. This approach increased the measurement accuracy (Yamamoto, Khorramdel, & Davier, 2013). PIAAC views numeracy skills on a scale from 0 to 500, which it sections into five levels<sup>3</sup> (OECD, 2013).

To exclude a possible bias arising from any gendered occupational segregation, different areas of work were included as control variables in the regression analyses. To exclude any effects of women working part-time, those participants who are unemployed, out of the workforce or work part-time<sup>4</sup> were not incorporated in the analysed data.

## **Method: Variables and analyses**

Variables on monthly income and leadership positions<sup>5</sup> serve as indicators of labour market outcomes. The income variable indicates the monthly income exchanged into US-Dollars and

---

<sup>3</sup> The score boundaries for numeracy in PIAAC are: 0-175 points (below level 1); 176-225 points (level 1); 226-275 points (level 2); 276-325 points (level 3); 326-375 points (level 4); 376-500 points (level 5).

<sup>4</sup> Excluding all participants who work less than 31 hours in an average week (D\_Q10).

<sup>5</sup> Variables names are EARNMTHALLPPP for monthly wages and J\_Q07a and J\_Q08a for leading positions.

transformed as purchase power parity (PPP). This way, all outcomes are given on the same scale. Both income and leadership variables include employees as well as self-employed workers.

The effect on monthly income was regressed with a multinomial linear model. Logistic regressions were used for the leadership positioning. On both occasions, three models were employed: Model 1 regressed against male gender and numeracy; model 2 added background variables (b.v.)<sup>6</sup> and model 3 regressed against the interaction term between numeracy and male gender. For the analysis on monthly income, the average work hours per week (h/w) were also controlled for in the first model.

### **Result: Same numeracy, different wages**

Table 1 shows the result of the first two models on the monthly wages; showing significant results<sup>7</sup>.

Country	adjusted for h/w	adjusted for b.v.	Average equivalent of income differences in numeracy points
Belgium	718 ***	977 ***	61
Czech Republic	719 *	756 **	n.s.
Finland	493 ***	664 ***	58
France	304 ***	385 ***	44
Germany	516 ***	686 ***	30
Greece	330 ***	395 ***	60
Ireland	565 *	905 ***	32
Italy	614 ***	703 ***	88
Norway	748 ***	994 ***	59

**Table 1: Difference of monthly income of men and women with the same numeracy proficiency**

The results indicate how much higher men's monthly wages are when having the same average numeracy proficiency as women. A comparison of the two models suggests that structural differences cannot explain men's higher wages, as in most countries the differences in income rise in the further adjusted model. In Norway, for example, women on average earn almost 1.000 USD (PPP) less than men despite having the same level of skill proficiency.

<sup>6</sup> Background variables include: Age (AGE\_C), educational qualifications (EDLEVEL3), the parent's educational background (PARED), native language (NATIVELANG), different fields of work (ISCO1C) and the average hours of work per week (D\_Q10)

<sup>7</sup> Significant results are marked as follows: \*\*\* (p < 0.001); \*\* (p < 0.01); \* (p < 0.05). n.s. (not significant).

The last column in Table 1 shows how many points on the numeracy scale are the equivalent of the gender difference in income. Men in these European countries seem to score from 30 (Germany, Ireland) to 60 (Finland, Norway, Greece, Belgium) to 88 (Italy) points lower on the 500 scale when earning a similar income to women. There are no significant differences in Denmark, Spain, Netherlands, and Poland.

### **Result: Exchanging numeracy into wages at different rates**

Table 2 presents the third model of regression on the monthly income. The analysis tested for the increase of income against numeracy proficiency – again, not for individuals but structurally. The table indicates how much additional skill points relate to higher income for men in comparison to women. For all genders, higher numeracy scores relate to higher income. However, for men higher numeracy points relate to a higher increase in income. The difference is smallest in Ireland (with Germany as a close second). Here, a man's increase equals 117 percent (118 percent) of women's. In Italy, men's income increase equals more than 140 percent of the average woman's increase in income.

Country	Men's increase in income compared to women's increase
Belgium	138 %
Finland	130 %
France	122 %
Germany	118 %
Greece	122 %
Ireland	117 %
Italy	141 %
Norway	129 %

**Table 2: Average value of men's numeracy in relation to women's**

There are no significant differences in Denmark, Spain, Netherlands, Poland and the Czech Republic. For all thirteen European countries, higher numeracy scores relate to an increase of income by 123 percent of women with equivalent scores.

### **Result: The probability of leadership**

Regarding the probability of men and women of getting into a leading position, we found similar results, which are shown in Table 3. These results show the effect coefficient of the binomial logistic regression analyses. The effect coefficient is the exponent of the regression results. In both models, men show a higher probability of being in a leadership position. In the unadjusted model, men in Italy and Germany are between 14 and 20 percent more likely to be in a leadership position when having equal numeracy skills as women. In Finland and Belgium, men are 81 and 89 percent more likely to be in a leadership position.

In the adjusted model, men in Spain and Finland are almost twice as likely to be in a leadership position as women with similar numeracy proficiency, educational background, in the same field of work, and with further background variables controlled. In the Czech Republic they show a more than two and a half times higher probability.

Women in Finland or Spain are almost half as likely to get into a leading position with the same numeracy proficiency, education and further background variables. There are no significant results in Ireland.

Averaged for all analysed European countries, men's probability to be in a leadership position is 148 percent of that of a woman with equivalent numeracy skills. When controlled for background variables, the overall average for men is 59 percent higher in relation to women.

Country	not adjusted	Adjusted for b.v.
Belgium	1.89 ***	1.62 ***
Czech Republic	1.75 ***	2.60 ***
Denmark	1.77 ***	1.52 ***
Spain	1.75 ***	1.93 ***
Finland	1.81 ***	1.95 ***
France	1.68 ***	1.65 ***
Germany	1.21 *	<i>n.s.</i>
Greece	1.52 **	<i>n.s.</i>
Italy	1.14 ***	1.61 ***
Netherlands	1.57 ***	1.37 **
Norway	1.55 ***	1.26 *
Poland	1.40 **	1.72 ***

**Table 3: Odds ratios of logistic regression results: average probability of men getting into a leading position compared to women with equal numeracy skills**

## Discussion

As a consequence of the use of IRT, plausible values and the nature of our calculations, these results cannot be interpreted at the level individual case. In addition, countries' results can't be compared because of the different economic positions and related purchasing power within countries. However, the strong and significant correlation in at least nine of the 13 analysed countries indicate strong gender differences in the way (numeracy) skills can be transformed into labour market outcomes.

Furthermore, it seems numeracy does not correlate (strongly) with all job-specific skills. In contrast, there is no reason to assume that the gender difference in numeracy is bigger than in other job-specific skills.

In this paper I have argued that numeracy is embedded in hegemonic structures of society in (at least) three specific ways: (1) influencing what is recognised in definitions of numeracy, (2) selecting who acquires numeracy, and (3) determining the societal value of numeracy skills. The analyses of PIAAC data could show women's numeracy skills relate to a lower income and to lower probabilities of being in a leadership position. On a scale of 500, men score between 32 and 88 point lower than women while having a similar income. With the same numeracy proficiency, men on average earn between 300 and 750 USD more than women. Similarly, men's probability of getting into a leadership position is around one and a half times that of women with the same numeracy proficiency.

In some cases, the adjustment of the model for various background variables increased the respective coefficients. This might indicate, that part of the gender differences in the labour market are intensified by (some of) those background variables, like different fields of work or educational attainments. This result, however, cannot be explained by the first model.

In conclusion, this study provides evidence that numeracy skills are entwined in power relations. A multitude of factors, which - in some way or another – appear to be influencing women's opportunities along gender lines, accumulate to different outcomes in the labour market. My analysis indicates that higher levels of numeracy skills relate to an increase in labour market outcomes – but it is not an equal increase for everybody. This might suggest a deeper reflection on our concepts of numeracy and skills and our willingness to use real-life outcomes as promises for numeracy education.

<sup>3</sup>HU University of Applied Sciences Utrecht, The Netherlands; [paul.drijvers@hu.nl](mailto:paul.drijvers@hu.nl)

*Numeracy and mathematics education in vocational education is under pressure to keep up with the rapid changes in the workplace due to developments in workplace mathematics and the ubiquitous availability of technological tools. Vocational education is a large stream in education for 12- to 20-years-olds in the Netherlands and the numeracy and mathematics curriculum is on the brink of a reform. To assess what is known from research on numeracy in vocational education, we are in the process of conducting a systematic review of the international scientific literature of the past five years to get an overview of the recent developments and to answer research questions on the developments in vocational educational practices. The work is still in progress. We will present preliminary and global results. We see vocational education from the perspective of (young) adults learning mathematics.*

*Keywords: Numeracy, mathematics, vocational education, VET.*

### Introduction

#### Practical background / Our aim

Vocational education in the main stream of the educational system in the Netherlands (preparatory vocational for 12- to 16-year-olds and specific vocational for 17- to 21-year-olds) is on the brink of bringing the curriculum up-to-date to the needs of the current society and the contemporary workplace. In the 1990s the curriculum was built around four domains: numeracy, algebra, geometry & measurement, and information processing & statistics. In that timeframe the curriculum was considered quite modern and ahead of developments in other countries, mostly caused by the Realistic Mathematics Education movement which was inspired by the “mathematics is a human activity” -approach by Hans Freudenthal (Gravemeijer, 1994).

In the 2010s, however, from an alleged low level of arithmetic skills of the students, a strong top-down ministerial policy was introduced by adding to the existing mathematics curriculum a separate numeracy/arithmetic programme with a digital nation-wide summative examination. After 10 years of piloting and political quarrels, this path was abandoned again.

Now new paths are explored to see whether the vast body of knowledge on mathematics for the workplace and mathematics for the future citizens can provide valuable clues for a modern, relevant and effective numeracy or mathematics curriculum for students who will work with mathematics in very practical situations and who will have to deal with the quantitative world around them. From this perspective the students in vocational education are seen as young adults who can benefit from the body of knowledge collected around adult mathematics education.

From this perspective we started a review of the most recent literature on numeracy in vocational education.

## Theoretical background

For a theoretical background, we address the following issues:

- Societal changes
- Shifts in mathematics education
- Previous reviews

To start with, there are major societal and policy pressures on (mathematics) education to prepare young learners and school leavers for a complex and technologised society. In literature, these new educational goals are referred to as *21<sup>st</sup> century skills* or *21<sup>st</sup> century competences* (Voogt & Pareja Roblin, 2012), *global competences* (OECD, 2016) or the *4<sup>th</sup> industrial revolution* (Schwab, 2016). Common among the concepts mentioned above is the acknowledgement that across education, government, and business, the skills and knowledge needed to succeed in work, life and citizenship have significantly changed in the 21<sup>st</sup> century. As workplaces are being transformed, the skills and knowledge workers now need are intertwined with technology. New means of communication and types of services have changed the way individuals interact with governments, institutions, services and each other, and social and economic transformations have, in turn, changed the demand for skills as well.

These major societal and policy pressures translate also into pressures on mathematics education to prepare young learners and school leavers for a complex and technologised society. For instance, PriceWaterhouseCoopers (2015) reported recently that businesses “competing in a global economy driven by data, digital technologies and innovation will need more employees trained in science, technology, engineering and mathematics (STEM). Research indicates that 75 per cent of the fastest growing occupations now require these skills” (PWC, 2015, p. 4). Similarly, in their recent 2017 review, the National Council of Teachers of Mathematics (NCTM) (2017), stated that “Today mathematics is at the heart of most innovations in the information economy. Mathematics serves as the foundation for STEM careers and, increasingly, careers outside STEM, and mathematical and statistical literacy are needed more than ever to filter, understand and act on the enormous amount of data and information that we encounter every day” (p. 6). Many of the mentioned changes are related to technological developments, particularly information and communications technologies (ICT), and have profoundly altered what are considered to be the key knowledge and skills that individuals need as economies and society continue to evolve.

There is a growing body of knowledge on the desired numeracy and mathematics competences in workplaces (D. Coben et al., 2010; Geiger, Goos, & Forgasz, 2015; Hoyles, Wolf, Molyneux-Hodgson, & Kent, 2002; Hoyles, Noss, Kent, & Bakker, 2010; Straesser, 2015; Wake, 2015). Consistent in the reported results are conclusions which boil down to the observation that the mathematics tasks which people undertake at work in the 21<sup>st</sup> century involve more than plain calculation skills or straightforward procedural proficiency. Nowadays, workplace practices involve sophisticated mathematical problem-solving skills and the ability to recognise and engage with the mathematics embedded within multifaceted, real-life workplace settings. Many 21<sup>st</sup> century

workplace mathematics requirements and practices are integrated with technology. Hoyles et al. (2010) argue that this requirement for mathematical capabilities is driven by the need to improve production processes and productivity, and that there will be greater demand for what they call ‘techno-mathematical literacies’. This involves “a language that is not mathematical but ‘techno-mathematical’, where the mathematics is expressed through technological artefacts” (Hoyles et al., 2010, p. 14). Furthermore, the pressures for moving toward the teaching and learning (and assessment) of 21<sup>st</sup> century skills include a consistent demand for students to be digitally and technologically competent, to be able to engage with technology in all its guises, and to be highly ICT literate (Voogt & Pareja Roblin, 2012).

There have been a few recent reviews on related topics. At the start of this century Coben (2003) did a comprehensive review on adult numeracy focusing on research and related literature. The results of this review are relevant to our research questions as far as vocational education can be considered as (young) adults who are learning mathematics. This is indeed the perspective we chose.

The main conclusions from Coben’s review were:

- Numerate practices are diverse and deeply embedded in the contexts in which they occur.
- The transfer of learning between contexts is problematic.
- The impact of adult numeracy tuition is under-researched and more detailed studies are required.
- Adult numeracy teacher education needs continuing professional development.

At the same time, Falk and Millar (2001) conducted a review of research on literacy and numeracy in vocational education and teaching from an Australian perspective. Their main conclusions were:

Significant and multiple implications for literacy practice have emerged from forces for change such as globalisation and technological advancement. (...) Adult and Community Education (ACE) and VET sectors have been merged to a large extent. These changes have had important consequences for the way practitioners carry out their work. (Falk & Millar, 2001, p.3)

The overall picture of adult education and vocational education and training (VET) is that it is a rapidly developing field with a strong focus on connecting mathematics education to the world around us. Effective practices to incorporate these ideas in courses and educational programmes are still under-researched.

### **Research questions**

In the Netherlands a broad curriculum reform has started which includes redefining the mathematics curriculum in vocational education. This review is also intended to collect scientific results of research on vocational policies and practices to support this process and make it more evidence-informed.

To get a better grip on how the concepts of numeracy and mathematics are used in the international scientific community our first research question is:

1. Which concepts of numeracy (or mathematics) are used in research in a vocational context?

Furthermore, we are interested in well-researched practices in mathematics or numeracy education in vocational tracks or streams. Hence our second and third research questions:

2. Which numeracy teaching practices are described in research in a vocational context?
3. Which effects of numeracy teacher practices are reported in research in a vocational context?

The review of literature is still ongoing. The results we report in the results section are preliminary and still quite general.

## **Method**

### **Search terms**

We conducted a systematic review (Gough, Oliver, & Thomas, 2017; Petticrew & Roberts, 2016) of the research literature through the definition of search terms derived from the research questions.

In various countries the concept numeracy is used when referring to the mathematical activities in the vocational classroom, for instance in Australia. In The Netherlands two words are used to distinguish the more basic numeracy as is taught in primary education (Dutch: rekenen) and the more advanced use of mathematics as is taught in secondary education (Dutch: wiskunde). In most countries, however, mathematics is used to refer to all the kinds of activities which deal with the numbers, patterns and structures in the vocational education or in the workplace.

Regarding the specific part of the educational infrastructure we are focusing on, two labels are used most common to refer to this specific kind of education which prepares students for the workplace. These labels are “vocational education” and VET, which is short for vocational education and training. So our main logical string of search terms is:

Search string = (Numeracy OR mathematics) AND (“vocational education” OR VET).

### **Search engines and databases**

We used our search string in a variety of educational databases which together assemble most international educational research: WorldCat, ERIC, PsycInfo, Web of Science, Scopus, and Education Research Complete.

### **Scope**

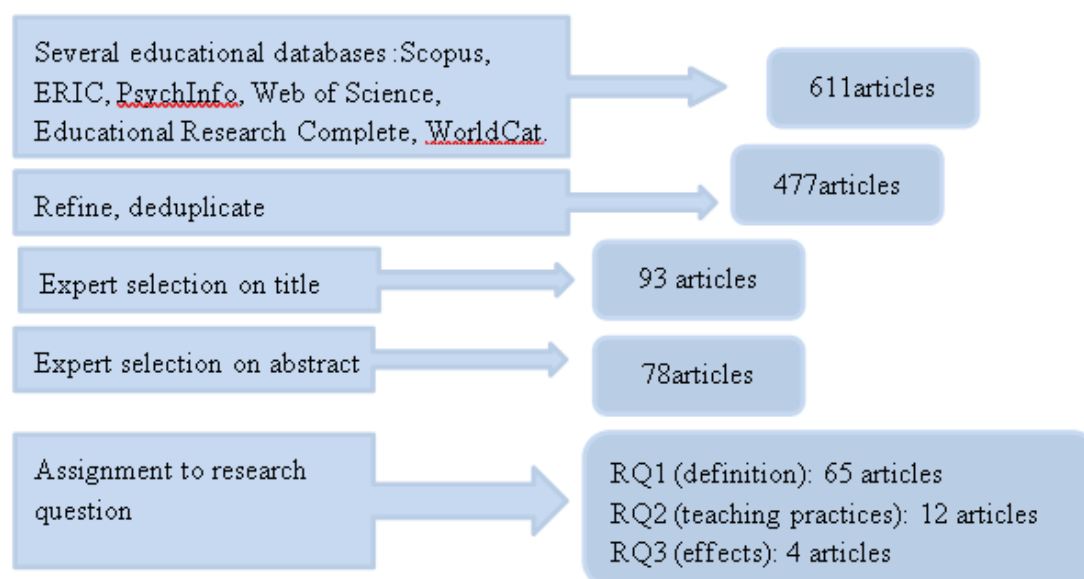

We narrowed down our search using the following limitations:

- Scientific literature
- Published in peer-reviewed journals
- English language
- Recent, last five years, date of publishing: 2014-2018 or 2014+.
- Search terms present in title, abstract, or keywords.

### **Further narrowing down**

The search-string led to 611 hits in the selected databases. There were several ways in which we narrowed down the amount of initial hits (see Figure 1).

First, the articles in this ‘technological catch’ were brought together, deduplicated and checked for obvious mishits, such as articles on veterans or veterinarian issues. This resulted in a set of 477 articles to be considered by experts.

**Figure 1: Search strategy and remaining articles after each step**

Second, the first expert screening followed, based on the titles of the articles. Three experts scored independently whether the article was supposed to be relevant for the three respective research questions. For each a score 1 (relevant), 2 (possibly relevant), 3 (maybe relevant) or 9 (not relevant) was given. After this, articles with three 9-scores by each experts (i.e., not relevant for any of the research questions) were discarded from the selection. This reduced the set to 93 articles remaining.

Third, the abstracts of the remaining articles were scored by three experts, again independently. The experts decided from the content of the abstract whether they supposed the article to be relevant for either of the three research questions. After this, again articles with three 9-scores by each expert (i.e., not relevant for any of the research questions) were discarded from the selection. This reduced the set to 78 articles remaining.

Fourth, the 78 articles were linked to the respective research questions to be examined further: 65 articles were judged to be relevant for research question 1 about the definition of numeracy, 12 articles seemed relevant to answer research question 2 about teaching practices and 4 articles were scored as relevant for research question 3 on the effects of teaching practices.

Fifth, the full text of the remaining articles are being analysed for relevant sections which can be used to answer the actual research questions. This analysis is ongoing.

### **Cross-referencing and snowballing**

In the next phase of our research, we will cross-reference our set of relevant sources with Google Scholar, which is nowadays considered to be the search engine which uses the most comprehensive database of products from the scientific community. However, the ways to refine searches in Google Scholar are still rather limited.

In a preliminary analysis of the remaining articles we found multiple references to specific books and journal specials (for instance, ZDM 2015, 47-4, and Educational Studies in Mathematics 2014, 86-2) of particular interest for our research questions. In a later stage of our research we will add some of these sources to the set of sources we use as corpus to answer the research questions.

## Results

The review is ongoing. The results and conclusions in this paper must be read as preliminary findings.

Regarding research question 1 - on the used definition of numeracy - we found that a large part of the articles address policy matters, like comparative studies (for instance PIAAC), country policies, regional and school policies, most of the cases assuming the definition of numeracy from the PIAAC framework as the working definition. In articles, which were not on policy matters, in roughly half the cases the definition of numeracy is not explicitly defined, making it difficult to value the inferences made from the gathered data. This problem will be elaborated in a later article.

Regarding research questions 2 and 3 – on actual practises - , the major conclusion is that from the found hits and relevant articles only a very few are addressing actual educational practices on numeracy in vocational education (12 of 477) and even fewer (4 of 477) report on effects of educational practices or interventions. Most of the 12 articles addressing educational practices describe observations in classrooms, providing conclusions and implications for education based on these observations. These articles tend not to be on describing current teaching practice and their effects, but in most cases report on how the authors would like to see the teaching practice change. The importance of real context in education for transfer of the numeracy-skills and motivation of the students is emphasized.

Some themes are reoccurring in the selected articles. First, all articles describe the importance of connecting numeracy to work-related situations. This transfer or boundary crossing is important since students can solve mathematical problems in class, but often do not recognize these problems in work-related knowledge; the integration of mathematics and statistics learnt in school with work related knowledge is a problem (Bakker & Akkerman, 2014). Wake (2014) speaks about ‘hidden mathematics’; workers (and students) do not recognize mathematical situations as such and therefore do not use school knowledge in work-situations. Dalby and Noyes (2015) as well as Coben and Weeks (2014) stress the use of ‘real work’ problems in which students can use mathematics as a tool, instead of the mathematics they know as a school subject. Contextual math provides motivation since students experience the need of it for their own work. According to Bakker and Akkerman (2014) students themselves report to appreciate a work-related approach and claim they learned a lot in only five one-hour meetings. Second, a reoccurring theme is problematic transfer from numeracy interventions to practice. Ter Vrugte et al. (2015) show in their research how in a math computer game proportional reasoning increases, but analyses of transfer problems showed that there was no measurable transfer. They conclude students in vocational education have trouble applying school knowledge in another context. Van Schaik, Terwel and Van Oers (2014) describe a science workplace in which students have to build a trike. This article shows how numeracy is predominantly hidden in other subjects, like science. And also in science transfer is

difficult for teachers to achieve. When given a practical assignment, students seem to forget the need to apply the knowledge they learned before, but also teachers do not always teach their students the missing school-math when they need it and connect the classroom knowledge with the practical assignment.

Only four articles provide experimental research in which a specific teaching practice, differing from the regular approach is being implemented. These articles are too small in number and too divers to find trend-setting answers to our third research question.

## Conclusion and Discussion

When we used the search string (Numeracy OR mathematics) AND (“vocational education” OR VET) is used in Google Scholar for products since 2014, we found 16,500 hits. There is no lack of output around these themes. Refining the sources to a corpus of relevant literature from which some conclusions could be drawn or trends could be discerned is not a straightforward task. The sources are multifaceted and of very different quality, scope and choice of themes.

The articles are from dozens different journals, which reflect the multifaceted character of both the concepts numeracy and vocational education. It also reflects that the research area is young, not well- established and literally ‘all over the place’.

The definition of numeracy used in the articles is influenced heavily by the work around the PIAAC Numeracy Framework. In that sense the PIAAC programme has a formatting power on the development of the concept of numeracy.

*This paper is a discussion paper to support an Erasmus+ project with the name Common European Numeracy Framework (CENF) (for adults) which will start at the end of the year 2018. In the first months of 2019 the team with participants from The Netherlands, Austria, Spain and Ireland will be in the process of collecting European examples of numeracy practices and current numeracy frameworks. At the conference we will show the results of this collection to date and the initial outline of a tentative CENF. We intend to spark comments, suggestions and insights from the participants of TWG07 - Adults Mathematics Education - to enrich the collection and as feedback on the initial outline of the CENF. Another aim is to create a network of national or regional stakeholders which will support the development of a shared framework for numeracy goals and numeracy education for adults in the 21<sup>st</sup> century.*

*Keywords: Numeracy framework, professional development, pilot courses, Erasmus+.*

### Introduction

In 2017 four educational institutes from The Netherlands, Austria, Spain, and Ireland respectively, took the initiative to develop a numeracy framework for adults. A grant was awarded by the European Union in an Erasmus+ project to work towards such a framework in the years 2019-2021.

As result of this project a tentative Common European Numeracy Framework (CENF) will be established and based on this framework a set of professional development modules (PDM) for adult numeracy educators will be developed. The CENF will incorporate the latest insights into numeracy skills and competencies which are relevant for our technologised and numbers-drenched society.

The suite of professional development modules developed for teachers and volunteers who teach on numeracy courses will be based on the CENF. The PDMs will foster the capability of teachers and volunteers to effectively develop basic skills and competences among adult learners in order to strengthen their employment prospects, develop their socio-educational and personal skills, and counteract social exclusion. It will also equip adult learners with the skills highly needed to participate in civic and social life.

In short, the objective of this project is to first develop a Common European Numeracy Framework and secondly to expand and to improve the number and the quality of numeracy courses (or other relevant educational activities) offered to adults to improve their life chances of prospering in

society. To reach this objective, we will use on a multi-level approach for addressing teachers and volunteers that are involved in the delivery of numeracy courses, the teacher educators who deliver courses to those teachers and volunteers, and policy makers and other stakeholders who are responsible for creating opportunities for such courses. This multi-level approach already has started by connecting the associated partners to our goals in this application.

The CENF will comprise of information on the effective teaching and learning of numeracy, especially in relation to adults who have left school early and those from disadvantaged backgrounds. Such a framework can also be used as a mechanism for systemically tracking and monitoring the progress of adult learners in the field of numeracy. The professional development modules will be made available on-line in an attempt to actively contribute to extending and developing educators' competences and maximize the chance of European wide use of the project outputs.

## **Background**

Too many European citizens lack the necessary numeracy competencies to participate autonomously and effectively in our technologized and number-drenched society. Consequently many citizens are overlooked for certain jobs and have problems in their daily life, dealing with the abundance of number-related issues. In literature, these competencies are referred to as 21<sup>st</sup> century skills' or '21<sup>st</sup> century competences (Voogt & Pareja Roblin, 2012), global competences (OECD, 2016a) or skills for "the 4th industrial revolution" (Schwab, 2016).

The results of the last PIAAC survey (OECD, 2013, 2016b; PIAAC Numeracy Expert Group, 2009) show that a quarter of the participating countries in PIAAC have results below level 2 of the 6-point scale. Scores below level 2 are associated with having problems in daily activities due to low numeracy skills. These results on numeracy give rise to serious cause for concern for the future economic development of Europe. This is an even more pressing issue since the amount of numerical data that needs to be interpreted and used is rapidly rising due to technological developments and the prevalence of (big) data. To gain a better insight in these trends a second cycle of PIAAC will be starting in 2020 (Hoogland, Diez-Palomar, & Maguire, 2019; Kirsch & Lennon, 2017; Tout et al., 2017).

On average, school leavers between the age of 16 and 24, perform at a lower level than people between the ages of 25 and 44 (OECD, 2016b). The lack of numeracy skills among these people increases the risk of unemployment and may influence family life and social inclusion. In particular, low-skilled workers are at risk in the labour market, particularly when faced with adaptations in the labour market. The Council of the European Union emphasizes that adult learning is a means for upskilling or reskilling those affected by unemployment, restructuring and career transition, while simultaneously it makes an important contribution towards social inclusion, active citizenship and personal development. The European Council recommends the enhancement of basic skills including literacy, numeracy, problem solving and digital skills as part of the Europe 2020 Strategy (European Commission, 2017).

In the frame of lifelong learning, therefore, adult numeracy education has an important role in the development of good programs for basic skills for the future.

Evidence-informed adult numeracy education may be the key for attaining the goals set out in the Europe 2020 strategy. In most European countries, adult numeracy education is a locally based endeavour with a plethora of practices, some efficient, some less so. Furthermore, there is a variety of underlying assumptions on what constitutes good adult numeracy education. The availability of a good collection of (piloted) professional development modules, based on the CENF (which contains relevant content and insights for adults learning numeracy and mathematics), will generate a quality adult numeracy education across Europe, and thereby contribute to policies and activities which address the low-numeracy levels in many European countries. Effective numeracy education in European countries, based on a common framework, may lead to a higher level of societal participation and inclusion of adults, and thereby to the improvement of the European economy.

### **Project methodology as starting point for workgroup discussion**

In this section we present the methodology which will be used in the Erasmus+ project (Hoogland, Diez-Palomar, & Vliegthart, 2019). In the working group of CERME11 we will use these headings as a guide for the discussion. The aim of this discussion paper is to inform the participants of TWG07 and to tap into their knowledge, experiences, and networks to strengthen the impact of the project.

The project methodology can be laid out as follows.

#### **The context**

The number of European citizens lacking the necessary numeracy competences to participate autonomously and effectively in our technologised and number-drenched society is a serious concern for the economic development of Europe. (OECD, 2012, 2013, 2016b; PIAAC Numeracy Expert Group, 2009). The European Council recommends enhancement of the basic skills - literacy, numeracy, problem solving and digital skills - as part of the Europe 2020 Strategy (European Commission, 2017).

Evidence informed adult numeracy education is the key for reaching the goals as mentioned in the Europe 2020 strategy. In most European countries adult numeracy education is a locally based endeavour with a plethora of practices, some efficient, some less so and with a great variety of underlying assumptions on what constitutes good adult numeracy education. A good set of (tried-out) professional development modules based on a common European numeracy framework (which contains relevant content and insights in adults learning numeracy and mathematics) will generate a qualitative and quantitative impulse in adult numeracy education across Europe, and thereby contribute to policies and activities which address the low-numeracy levels in many European countries.

#### **The objectives**

The ultimate objective of the project is to enlarge the number and to improve the quality of numeracy courses (or other relevant educational settings) offered to adults to improve their chances in society. To reach this objective we develop a Common European Numeracy Framework (CENF) and set of professional development modules (PDMs)

### **The target group and the participants in the project.**

The ultimate target group of the project are the participants in adult numeracy courses. The aim is to provide them with numeracy competences which will benefit them in participating adequately in daily life and work-related situations in our number-drenched society. Numeracy to this regard is considered to be a social practice (Yasukawa, Rogers, Jackson, & Street, 2018). However, the availability and quality of adult numeracy courses around Europe are dependent on many factors, of which many are outside the scope and influence of this project. Therefore, we choose a multi-level approach of addressing teachers and volunteers who are actually involved in the numeracy courses, the teacher educators who provide courses to those teachers and volunteers, and policy makers and other stakeholders who are responsible to create opportunities for such courses (both by teachers and by teacher educators). In doing so, the project will involve the local, regional, national and international communities of practitioners, researchers, and policy makers around adult numeracy education by information, surveys, presentations, and presenting a CENF.

### **The activities**

On the basis of literature studies and broad European surveys on used frameworks, good practices, and theoretical insights we will develop a draft framework and draft modules. This will be followed by try-outs in the partner countries to test the drafts empirically and to collect feedback from various stakeholders from the adult numeracy community. The framework and modules will be revised with the gathered experiences, evaluations and comments. The end result will be made available as a blended on-line course, while the availability as cMooc will be investigated.

### **The methodology**

The ways of gathering the information are literature reviews, surveys and peer reviewed development of products, according to academic standards for research methodology.

The methodology for dissemination, implementation and sustainability is based on the multilevel approach of educational changes as for instance propagated by Hargreaves, Lieberman, Fullan, and Hopkins (2010) and Fullan (2008); Fullan, Hill, and Cr  vola (2006).

### **The result**

The result will be an increase in the quality and quantity of numeracy courses and professional development courses on adult numeracy education. The concrete results of the project are a CENF and a set of PDMs for teachers and volunteers who work in adult numeracy education. Both output we consider as essential in reaching the ultimate objective.

### **The impact**

The existing European networks on adult numeracy education support the project as associate partners and express their willingness to advocate the results through their network communications and in their network meetings. The CENF will have an impact across Europe.

## **Long term benefits**

A common approach and a reinforcement to create high quality national professional development courses based on a common framework can have a long-lasting effect on the development of high quality adult numeracy education around Europe.

## **Discussion**

The discussion points on the starting project followed the project methodology. Below, to each discussion point a short outcome of the discussion in the Thematic Working Group is mentioned

### **The context and the objectives**

Q: What should be added to the context to make the picture more complete or richer in examples?

A: Special attention is needed for participants who are vulnerable learners, often with negative educational experiences.

Q: Can a Common European Numeracy Framework be helpful in the further development of adult numeracy education?

A; Yes, as long as it is developed bottom-up and connects to existing practices and frameworks.

### **The target group and the participants in the project.**

Q: Should the framework aim at participants in adult numeracy courses, at practitioners in adult numeracy education in the European countries, at adult numeracy course designers, or at policy makers?

A: Both practitioners and policy makers must be able to read and understand the framework. For participants materials can be designed which are closely relate to the framework, for instance rubrics or descriptions of typical behaviour.

### **The activities, the methodology, the results of the project**

Q: Which other activities are paramount to reach the envisioned goals?

A: The project would strengthen as the participants' voices were heard in the developmental stages of the framework. The participants are adults who have an opinion on how learning goals could and would look like.

Q: Which activities should be added to make the results stronger and more widely-spread?

A: The design and the implementation of the framework would benefit by international parallel research and validation of parts of the framework

### **The impact and the long term benefits**

Q: Which actions might increase the chance to reach a really *common* European Numeracy Framework on adult numeracy education? Who are the most important stakeholders?

A: Both policy makers and networks of practitioners and researchers are important. Translating the framework in as many European languages as possible can help the acceptance and use.

The results of this discussion will be input for the further development of the Common European Numeracy Framework..

## Acknowledgement

This project is carried out in an European project Common European Numeracy Framework with the support of the Erasmus+ programme of the European Union.

# What motivates adults to learn mathematics through trade unions in the workplace: social factors and personal feelings

Beth Kelly

University College London/ Institute of Education, United Kingdom; [beth.kelly@ucl.ac.uk](mailto:beth.kelly@ucl.ac.uk)

*This research is based on interviews with adults about their motivation to study mathematics in the workplace, through classes organised and funded by trade unions in the UK. The findings point to motivation as a function of individual's emotions and cognition that are influenced by social experiences. The research identifies a difference between the initial motivation to re-engage with learning and that required to continue, or persist. Continuing learning relies on a socially and emotionally supportive learning environment which adults identify as 'different' from previous experiences. The term an 'Affective Mathematical Journey' is developed to describe the positive emotional changes experienced by adults, which helps them overcome negative memories. The adults' resultant increase in confidence and motivation encourages them to successfully develop and use their mathematical skills both inside and outside the classroom.*

*Keywords: Mathematics, motivation, teaching methods, affect, emotions.*

## Introduction

There is much research into learning mathematics that seeks to explain why children and adults have problems with the subject and subsequently struggle to learn mathematics (Boaler, 2000; Coben et al, 2007). Those interviewed for this research reported obstacles to their learning such as; previous unsuccessful learning experiences, demands of shift work and family responsibilities. Yet they had chosen to re-engage with learning mathematics at or below GCSE level in the workplace through opportunities negotiated by trade unions with employers. It was not a requirement of their current job, so this group of adults must have been highly motivated to return to learning mathematics and were chosen to develop a better conceptual understanding of motivation.

The adults in my research have taken up a learning opportunity at work enabled by national trade unions allocating resources to this purpose. Trade Union officers, usually ULRs, are activists whose job it is to encourage workers to develop their skills, give advice and guidance, identify workers needs, and negotiate on-site learning opportunities with employers). Trade unions fund the teachers and equipment needed to support that learning, while employers provide the physical space and sometimes time off work to learn. In 2016, nearly 10,000 ULRs across the UK were involved in training through TUC Education and over 27,000 individuals took up an opportunity to improve their English and maths skills through their union (Unionlearn, 2017, p. 4).

This research identifies the importance of how people feel about the learning in relation to their motivation. Adults need to trust people who are encouraging them to join the classes and feel safe in the learning environment in order for them to develop confidence with mathematics. Union Learning Representatives (ULRs), are trusted colleagues that play a key role in encouraging and supporting adults to join classes in the workplace. Trade unions also promote a 'different' learning approach in their courses, influenced by the 'collective ethos' of trade union culture. The learners identify this different pedagogic approach as key to them persisting learning (Kelly, 2018).

Research into learning in the workplace has usually focused on mathematical concepts used for work or the more contentious notion of the ‘transferability’ of mathematical concepts between school and the workplace (Lave & Wenger, 1991; FitzSimons & Godden, 2000). In an endeavour to understand differences in learning approaches research has also usefully included descriptions of pedagogical characteristics (Evans, Wedege, & Yasukawa, 2013) in terms of formality: this research concentrates on adults’ motivations to learn mathematics in the workplace, to gain a formal qualification in a less-formal learning setting.

Research into affective issues in mathematics education have been explored by McLeod (1994), who conceptualised emotions, attitudes and beliefs in relation to motivation in terms of stability and intensity. Eynde, De Corte and Verschaffel (2006), posited motivational concepts act in different levels of social contexts. Hannula (2012) further theorised affect in mathematics education suggesting it could be explored in three dimensions, as concepts: cognitive, affective or motivational; as varying in relation to time and in relation to ontological traditions of research. This moves us on from simply identifying ‘maths anxiety’ (Buxton, 1981) as an emotional barrier to learning, to exploring the wider, more complex domain of affect in relation to motivation to learn.

During this research, the concept of an *Affective Mathematical Journey* (AMJ) was developed to describe changes in learners’ feelings in relation to mathematics. An AMJ occurs when positive (or negative) learning experiences inspire adults to modify their feelings towards mathematics. In this research, the change in affect becomes more positive and this change not only contributes to adults’ increased confidence and motivation to learn the subject but also influences their potential to use their new skills beyond the classroom. Elliot, Dweck and Yeager’s (2017) research supports these findings recognising the possibility of ‘socialisation practices’ to foster different mind-sets in learners which have a ‘cascade of effects, altering their meaning systems and their academic outcomes’ (p. 135).

Research by Hannula, Pantziara, and Martino (2018) highlighted the tradition of research into affect and mathematics education in CERME conferences, but the focus is still on school education. Boaler’s (2000) research into motivation and mind-sets has also focused on children. This research points to the contribution that adults who experience a ‘stalled education’ can add to research into affect and mathematics education.

## **Methodology and methods**

The analysis is based on twenty in-depth semi-structured interviews with members of trade unions, aged between 25 and 65, twelve males and eight females. They come from a range of trade unions, employed in a variety of contexts, in small and large organisations, publicly and privately owned. They studied in a variety of environments; individually following on- line courses with tutor support or in teacher-led groups. However, this is small sample with no claim to be representative of the characteristics of the broader union learning population, especially since learners who were studying basic mathematics up to level 2, the equivalent to a GCSE.

The identification and recruitment process of interviewees relied upon the agreement and support of trade union officers and ULRs. Hence the method of sampling was a combination of purposeful, ‘criterion sampling’ (Bryman, 2012, p. 419), as I was seeking adults that fulfilled a particular set of criteria and snowball sampling (Atkinson & Flint, p. 275) in that I needed key gatekeepers (ULRs)

to agree to help me access potential participants. The research centres on individuals and their ‘interpretations’ of situations, so naturally relies on qualitative data, which was tested for the trustworthiness and authenticity of the findings (Bryman, 2012, p. 390). The whole interview and storage process followed BERA (2011) guidelines, ensuring interviewees anonymity especially when their words would be used in the research. Nvivo™ was utilised to help track and analyse the learner’s words. Enabling me to interrogate the data and build and group ideas in different ways; as well as identifying commonly used words such as ‘confidence’.

The analysis takes a critical approach because the researcher is a teacher trainer who explores how research into adults learning in the workplace might usefully influence mainstream mathematics education practice. The research is also built on the feminist research tradition of exploring personal viewpoints, as Reinhartz and Davidson (1992) suggests when citing Datan (1989, p. 175) ‘it is an axiom of feminism that the personal is political’ (p. 234). Therefore, when analysing the adults’ words there is a subjective encounter with the individual that seeks to understand different perspectives, relating this motivation at the individual level to emotions and cognition, within particular social contexts.

Hence in this research, motivational factors are considered at three levels: the individual, the social and the societal, which all influence each other. At the individual or personal level McLeod (1994) focuses on needs and goals. Evans, Wedege and Yasukawa, (2013) broaden the notion of personal motivational factors to include ‘the cognitive and affective as part of the whole person’ (p.222). In this research individual learners feelings are key to their descriptions of their motivations to learn mathematics, reflecting Hannula’s (2012) dimension of the ‘domain of affect’ linking cognitive, motivational and emotional factors.

At the social level, local face-to-face groups include people who adults trust and influence their motivation (Barbalet, 1996), such as; fellow learners, families, union members and Union Learning Representatives. Families play an important support role but ULRs and fellow learners also play a key role in motivating trade union members to engage with learning and persist in classes.

The wider socio-economic environment, is a context where individual members are given a ‘second chance’ to learn mathematics through trade unions who have negotiated resources with both central government and employers to enable this to happen. Therefore, the social context of learning is influenced by the values, history and culture of both the trade union movement and the workplace, acting in wider United Kingdom society.

## **Findings**

### **Motivation to learn mathematics: initial and continuing**

Adults in the sample indicated their initial motivation differed from that required to continue or persist in learning. Their initial motivation to re-engage with learning was related to their individual needs and goals, such as: improving job security, filling a perceived personal knowledge or skills gap, gaining public recognition of their knowledge or skills through certification and helping their children. However, their motivation to re-engage with learning was also supported and encouraged by significant social local face-to-face groups such as work colleagues, ULRs, fellow trade union colleagues, other learners and family members. At the wider societal level, the opportunity for

learning is reliant upon trade unions negotiating funding with central government and workplace agreements with employers, as stated above.

Motivation to continue, or persist, with learning relied more on the action of the social face-to face groups, both teachers and fellow learners providing what the interviewees called a ‘different’ learning experience to that previously encountered. The adult’s described the characteristics of the learning as: more collaborative than previously experienced, taking place in smaller classes, in a relaxed atmosphere where they felt they could talk openly about mathematics and their problems. They also spoke about the mathematical topics being relevant to their life experience, in the sense that the concepts, where possible, were related to practical applications (such as building a shed) or finances (interest rates) or trade union issues (regarding health and safety).

### **Emotions and motivation**

During the analysis it became clear that emotions played a key role in the adults descriptions of their learning experiences. Eight people, out of twenty interviewed, used such words as hate, phobia, fear and horrendous to describe their previous experiences with mathematics. When talking about the learning organised through the trade unions seven interviewees spoke about feeling more “relaxed”, four described the learning experience as “fun” and five as “brilliant”. When discussing their motivations to learn and use mathematics eleven interviewees used the word ‘confidence’ to describe the changes in their *feelings* and *beliefs* about their abilities and motivation.

The notion of developing confidence through the achievement of mathematics contributed to the interviewees being more motivated to learn in the classroom but also to act differently when outside. For example, when they were negotiating on behalf of fellow trade union members, dealing with home finances, training to become trade union mathematics teachers or supporting children to learn mathematics at home. Combining personal feelings (of confidence) developed through social experiences (learning mathematics) creating those intentions to act differently, I describe this as adults experiencing a positive *Affective Mathematical Journey*, relating motivation to emotions, and cognition.

### **Relevance of the Findings to the Research Field**

When considering the notion of increased confidence adults’ motivation to learn mathematics relates to affective domains, reflecting Hannula’s (2012) two dimensions of motivation acting at an individual emotional and cognitive level but something that can change over time. However in this research the support of various members of local social groups was also key to learning, reflecting Eynde et al’s (2006) focus on the dynamic interaction between the individual and the social group.

### **Developing individual’s Confidence: an Affective Mathematical Journey**

Interviewees often used emotional words when discussing their motivation to learn mathematics, indicating that successful learning experiences, especially after previous ‘failures’, lead to changes in how they saw themselves and how they act in social situations. Psychological research into motivation reinforces the idea of a positive correlation between self-confidence and achievement in mathematics (McLeod, 1994; Zan et al. 2006). This research suggests that achievement increases self-confidence while Hannula (2012) argues self-belief and achievement are reciprocal influences.

Although theoretically confidence can be a problematic concept when used to judge others, the way the interviewees use the term to describe their own beliefs and feelings about themselves and their willingness to act in different social situations, suggests it as an ‘emotion of self-projection’ as described by Barbalet (1996, p. 77). McLeod (1994) argues confidence is mainly cognitive but the emotional words used in this research reinforce Barbalet’s (1996) argument. Mahn and John-Steiner (2002) further maintain developing confidence has a strong social dimension developed through group activities, which strengthens the findings of this research suggesting the use of the word confidence links the adult’s motivation to emotions and social experiences.

When adults report feeling more confident about themselves and more positive about learning mathematics it suggests a change in their identity development at a ‘profound’ level after a ‘transformative’ learning experience (Illeris, 2014). The conjecture is that feelings towards mathematics can change and effect an individual’s motivation and this concept contributes to the theoretical construct an *Affective Mathematical Journey* (AMJ), where adults’ beliefs, motivation and feelings about mathematics change. DeBellis & Goldin (2006) argue a range of emotions are experienced during problem solving in the mathematics classrooms, describing them as ‘pathways’, this research builds on that idea but points to changes in adult’s emotions happening over a longer period of time, in some cases years, thus it is more of a journey.

Further research could be undertaken, exploring ways that enable adults to experience *Affective Mathematical Journey* in relation to ‘different’ learning experiences described earlier. Particularly so for teachers in Further Education in the UK who have to teach 16-19 year olds, who have already experienced failure to achieve GCSE mathematics, at least once.

### **The role of different social face-to-face groups in motivation**

Bandura (2004) identifies social persuasion as key to motivation, this goes beyond verbal persuasion alone, because getting someone to attend a mathematics class would not be enough to develop their self-efficacy. Adults also need to feel supported in order to achieve and to develop their own self-belief. In this research trusted ULRs take on this role persuading members to join mathematics classes; ensuring the classes are accessible and providing a supportive and ‘emotionally safe’ environment (discussed below), leading to positive learning experiences.

Helping children with their skills development is also an important motivator for adults, particularly for females, findings supported by research by Swain, Baker, Holder, Newmarch, & Coben (2005) and Coben et al., (2007). This research accentuates the importance of supporting children as both an initial motivational force to re-engage with learning as well as a reason to persevere. For those adults who are newly arrived in the UK, with English as their second language, supporting children to learn can also help them to understand and integrate into the wider ‘home’ society. Hence, learning mathematics can be a positive contributor to a better functioning family in both economic and social terms.

### **Motivation related to pedagogical approaches used in the learning group**

The adults spoke regularly of the importance of having a ‘different’ learning experience, when re-engaging with mathematics. The pedagogical approach promoted by trade unions (Rees, 2007) and described by adults was ‘more relaxed’, ‘more social’ and ‘supportive’; closer to notions of

informal or non-formal (Coben et al., 2007; Evans et al., 2013) ways of learning. The learning experiences were described by some as being ‘easier’ than previous ones linking cognitive to emotional factors in motivation.

Bibby (2002) suggests there is a connection between traditional mathematics class and shame, where mathematical tasks are often seen as right or wrong and in the classroom are open to public scrutiny, judgement and, if not ‘correct’, humiliation and shame. Wojecki calls these remembered encounters as ‘wounding learning experiences’ (2007, p. 170) although he posits that adults can and do get over them, something this research supports. Schorr and Goldin (2008) argue it is possible to facilitate changes in emotions given the right circumstances, which they describe as ‘emotionally safe environments’ (p. 131). This is a place where it is safe to expose misconceptions and where learners’ will not suffer public humiliation for getting a calculation wrong.

The interviewees also spoke about the importance of relating the mathematical practice to previous and current experiences in life and work, an approach trade unions promote (Rees, 2007). Linking mathematics to life or work links to the idea of social belonging and relatedness, (Ryan & Deci, 2017) where motivation is something that is culturally relevant, such as trade union activities, or meaningful to the individual, for example calculating interest rates on loans.

## Conclusion

The findings indicate that adults’ initial motivation to re-engage with learning mathematics can be understood differently from their motivation to continue learning, but that both rely on the dynamic interaction between the individual and social groups. Motivation can be seen as a change in behaviour, which is a function of an individual’s motivation, emotions and cognition; developing within social face-to-face groups, all acting within a wider enabling social context.

The research has focused on a special group of learners, that have not succeeded in mainstream education but have achieved in an alternative learning environment that gives us a real insight into ways that adults’ motivation and confidence to learn mathematics can be developed. It foregrounds the important role that social face-to-face groups such as trade unions play in developing ‘different’ learning experiences using less traditional or formal methods but that can be successful in developing adults’ mathematical skills and confidence. It also highlights the important role personal emotions play in a motivation, and how trust in others plays a key role in re-engagement with learning, overcoming long held negative views on mathematics and developing confidence with mathematics. This change in feelings in relation to mathematics can be described as them experiencing a positive *Affective Mathematical Journey* (AMJ), where they feel more confident and motivated to both learn and use the subject.

*Adults know more about mathematics than they think and use it more often than they realise. Despite their apparent self-perception of being a 'non-maths' person, they behave in mathematics-informed ways, which are dismissed, routinely, as common sense or anything but mathematics. The doctoral research underpinning this paper reports that given the opportunity to view their behaviour, especially in work, through a mathematics-sensitive lens, people readily recognise their numerate behaviour even if they talk about it in different ways. This work introduces a set of tools and a methodology to harvest real tangible benefits for the learner. The tools explore the locus of a person's expertise in increasing granularity, to build a platform from which to capture a learner's mathematics knowledge, skills and competence (MKSC), to revise the mistaken self-perception and to inculcate confidence in his/her learning of mathematics.*

*Keywords: Numerate behaviour, invisible mathematics, workplace, non-maths-person.*

### **Introduction**

The phenomenon of 'invisible maths' has been explored and explained across a spectrum of political, educational, industrial, technological, economic, psychological, personal, and anthropological and social themes (Benedicty & Donahoe, 1997; Coben, 2008; Hoyles, 2008; Hoyles, Noss, Kent, & Bakker, 2007; Maaß, 2005; Strasser, 2003; Wake & Williams, 2007; Wedge, 2010). It encapsulates the paradox that people deny their use of mathematics or dismiss it as common sense or anything but mathematics (Coben, 2000). It is common for people to declare themselves as 'not a maths person' while behaving in numerate ways. This doctoral research offers a key to resolving the use/denial paradox, not only as an end in itself, but to help people to recognise their mathematics knowledge, to embrace it, and to be able to repurpose it to different contexts and for different outcomes. This paper takes a broad view of people as workers and people as learners or prospective learners. The term 'practitioner' denotes a person trained in the support of learners.

In companion documents, the authors provide a comprehensive explanation of invisible mathematics and how it arises. (Keogh, Maguire, & O'Donoghue, 2016; Keogh, Maguire, & O'Donoghue 2018). The purpose of this paper is to draw attention to how practical benefits can be harvested for the learner or worker as learner, given all that is known about 'invisible maths', and its consequences for individuals, their families, their communities and society as a whole. That formal learning of mathematics takes place in the classroom is self-evident. The expectation of such learning being somehow transferred to another context is rendered problematic (Evans, 1999) for

want of a channel through which the transfer to a contrasting context may be facilitated. This compounds the challenge to recognise mathematics outside of the classroom, partly because it is not conveniently packaged and labelled as discrete pods of MKSC that reflect a syllabus. For the purposes of this work, MKSC is determined by the context in which it is realised and refers to instances of behaviour that are underpinned by the ‘big ideas’ of mathematics, viz, Quantity & Number, Space & Shape, Pattern & Relationship, and Data handling & Chance. The focus in work shifts away from mathematics, to the achievement of aims and objectives, guided by processes and procedures, which, nevertheless, are shaped by mathematics concepts and thinking. In this way, we suggest, people develop high levels of expertise in the performance of the activities without appreciating the extent of their ‘knowing’ which underpins their ‘doing’. Adults are smart in a variety of ways that reflect their lived experience both inside and outside the classroom. The self-perception of not being ‘a maths person’ seems to prevent the recognition of mathematics activity, while assimilating it as common sense or ‘just part of the job’. To this end, the authors have developed a process and a suite of supporting tools.

The overall purpose of this process is to make explicit a person’s capacity for, and use of, mathematics that might otherwise remain hidden from view and unavailable for development. This is important in a dynamic landscape where employability and re-employability of workers, the recognition of their prior learning (RPL), and their continuous development is of paramount concern for themselves, their employers and society in general.

## How the tool and the approach works

### Process Stage 1: Use of Mathematics Survey (Tool 1)

The Use of Mathematics Survey consists of a set of 37 statements, 8 of which are included as exemplars due to space restrictions in Table 1. The full survey is amenable to translation into other languages and is available in a book entitled *Adults Mathematics and Work: from Research into Practice* (Keogh et al., 2018). For each statement those being surveyed are asked to rate how often they do the things suggested in the statements with the stated caveat that there are no wrong answers because what is of interest is their opinion about their job. For each statement participants select the option which most closely matches their opinion from this list: *Never or Hardly ever; About once a year; About once a month; About once a week; About every day; Don’t understand the question*.

The workplace survey instrument may be self-administered or completed with the support of a practitioner, depending on the learner’s needs and starting point. It is designed to prompt self-reflection on the learner’s activity, whether social or professional, by locating him/her in the midst of his/her own expertise. In this way, the learner begins to appreciate the mathematics underpinning the work and/or play and to realise that the impact of mathematics ranges across space and shape, pattern and relationship, data and chance, as well as quantity and numbers. It presents a mathematics-nuanced perception of what may be seen otherwise as common sense or anything but mathematics.

I interpret information from a variety of sources to form an opinion about a work/hobby situation.
----------------------------------------------------------------------------------------------------

I use measurements to describe the solution to a work/hobby problem.
----------------------------------------------------------------------

I apply ready-made solutions to familiar problems that arise in work/hobby.
I notice a problem in work/hobby when the measurements and dimensions seem to be out of line with the usual.
From among possible solutions, I select the one most likely to solve the immediate problem.
When trying to solve a work/hobby problem, I take into account that a change in one part of the problem could have an affect on another part.
I use my knowledge of the system to trace fault back to the cause.
I think about the shapes involved in a problem to find the solution.

**Table 1: Use of Mathematics Survey (extract)**

While the frequency of use of MKSC is not important at this stage, it invites the learner to reflect on a behaviour that may have become embedded in a habit-forming routine through repetition. More importantly the learner becomes more tuned to the mathematics-informed activities comprising the job that may have become invisible. This outcome may be sufficient in itself by succeeding in shifting the learner's dismissal of MKSC to one of accepting the prominent presence of mathematics in their activities, however it may be talked about. That realisation sets the learner up for a deeper exploration of his/her mathematics-disposition and is a prelude to a discussion regarding the context in which his/her work occurs.

### Process Stage 2: Task Context Tool (Tool 2)

The Task Context Tool (TCT) is designed to be used by a trained practitioner. It comprises a series of questions in the Socratic style (see Table 2).

Question	Purpose
Tell me about your work, hobby, past time.	Locates the learner in their comfort zone, where they are expert.
What happens there?	Invites the learner to explain; helps the practitioner to ask relevant questions and to understand the answers, in addition to recognizing gaps in the explanation.
Why?	Open questions such as why, when, who, and how helps to describe the context in which the work takes place and may reveal issues that would be assumed.
How do you know what to do?	Helps to locate the learner in work among the surrounding streams of work.
What happens next?	Reveals that which might remain concealed.
How does that happen?	Elicits detail that might be assumed to be common knowledge or self-evident.
Have I got this right so far?	Check for accuracy bearing in mind that the learner may not have discussed work in such detail before.
What have I left out?	Check for completeness.

**Table 2: Task Context Tool: suggested questions and their purpose**

The TCT is not intended to be a prescribed script, but rather an illustration of the type of questions that help the learner to begin to unpeel the layers of familiarity, habit and routine that hide the detail of the work environment. With a little training, a practitioner can produce a model of the broader context in which the 'job' takes place in a way that makes sense of the workflow to the outsider. It is crucial that, no matter what familiarity practitioners think they have with the job being described or their prior knowledge derived in other circumstances, they must put that and its inherent

assumptions to one side and listen carefully to the learner. The TCT is not usefully self-administered as it would allow the assumptions to remain embedded and concealed. The expected outcome is a ‘work-flow diagram’ that depicts the flow of actions and information that underpin the aims and objectives of the work activity, including the attendant motivations, constraints, conditions and problems. The suggested questions neither challenge nor judge, but intend to place the practitioner in the learner’s shoes, Table 2. The conversation between the practitioner and the learner is an iterative process as the learner recalls more relevant information.

The work-flow diagram of the context serves to acquaint the practitioner with the locus of the learner’s area of expertise, rapidly, to ask intelligent questions and to understand the answers, to enable a closer understanding of what the job/leisure pursuit entails in terms of the tasks that are ‘done’, in order to access the extent and kind of the underpinning ‘knowing’. Having established the surrounding circumstances, and having taken account of the relevant discourse, the essence of the job can be explored in more granular detail.

### Process Stage 3: Task Exploration Tool (Tool 3)

The next stage of the process sees the practitioner use the Task Exploration Tool (TET) to drill more deeply into what the learner actually does in order to uncover the numerate behavior that s/he exhibits. This is a more detailed enquiry of the processes and procedures that guide the work activity rather than a list of duties and is informed by the outcome of the context tool (see Table 3).

Question	Purpose
What is the first thing you do on arrival in work?	This question places the learner at the beginning of his/her day and is an <i>aide memoir</i> .
Why?	This is intended to expose the rationale of the learner’s approach to his/her work or hobby.
What happens next?	This enables conditions and constraints that influence following activities to be articulated and to explain how they are evaluated, talked about and reconciled.
How do you know what information/resources you need?	Allows the different kinds of input for the job and hints at identifying, evaluating, talking about and acting upon mathematical information in a variety of forms.
What can go wrong?	Invites a discussion about systems, patterns, relationships and chance, as well as shape, space and quantity.
What solutions have you for when things go wrong?	Introduces a range of topics that arise in the case of a breakdown in the ‘system’ for whatever reason, whether equipment, non-conforming product, incomplete documents or instructions.
How can you avoid things going wrong?	This is likely to introduce patterns and relationships, data handling and chance.
What makes things awkward?	This is an exploration of non-routine activities.
How would you change your work?	The learner’s insights offers the possibility of uncovering a deeper understanding of the MKSC that underpins the work.
What causes you trouble?	This shines a light on non-routine activities.
How do you deal with it?	Offers insights into the learner’s thinking style.
What is not covered by the SOPs (Standard Operating Procedures)?	Explores how the learner manages to anticipate problems that may be overcome by his/her ingenuity.
How do you work around problems?	This is another opportunity for the learner to articulate how smart s/he is.

What makes one day different from the next?	This is another opportunity to capture the complexity of the job as distinct from an account of the routine.
What's the last thing you do?	The answer to this question may be revealing regarding anticipation, chance and planning.

**Table 3: Task Exploration Tool: Suggested questions and their purpose**

Particular attention should be paid to codified references and acronyms that tend to conceal rather than explain. While many of the task components may be superficially repetitive, they can be constrained by sets of conditions that temper the worker's responses.. This is not an exhaustive list of questions, nor should it be considered a prescribed script, but a methodology for stripping back the occluding layers to access detailed numerate behavior. The information provided should be sufficient to enable the development of a diagram of the relevant actions and their conditions described in as much detail as possible, such that they may be numbered for inclusion in the Linking Tool (Tool 4). The role and aims of the practitioner are key in determining the appropriate level of detail. The combination of the Survey, TCT and TET will reveal range of instances of numerate behaviour to the learner and help them to overcome their 'non maths-person' bias. However, the practitioner may wish to map the numerate behaviour on to the local framework of mathematics described in terms of the 'big ideas' of mathematics viz, Space & Shape, Pattern & Relationship, Quantity & Number, and Data-handling & Chance, and to calibrate the evidence-based starting point level at which the learner's development can continue. This step is supported by the Linking Tool.

#### **Process Stage 4: Linking Tool (Tool 4)**

The Linking Tool (LT) is a template to help the practitioner to organize the information elicited by the other stages and mapping them to the underpinning mathematics concepts, for a particular job e.g. warehouse picker in this case (see Figure 1).

In the course of the application of these tools, the practitioner is tuned to hear clues as to the numerate behavior embedded in the activities the learner describes. This enables the practitioner to establish the link to the Irish National Framework (QQI, 2012) and to demonstrate the learner's familiarity with the underlying mathematics concepts with which they have demonstrated their familiarity, albeit expressed in non-mathematics terms.

It must be borne in mind by the practitioner that work is designed to achieve an outcome for the benefit of the employer without regard to the curriculum, topic disciplines or levels of complicatedness. It is unlikely that all of the requirements of a credit-bearing course of study would be contained in a particular job.

#### **Why does it matter?**

The denial/use of mathematics paradox is well established. So too is the self-declared perception of not being a maths-person as though it was a binary condition. The negative effects of insufficient MKSC is well documented regarding limiting life-choices. That a person may constrain their development due to a mistaken perception of their capacity for mathematics is unjust and unjustifiable, not only for themselves but for those over whom they exert influence, i.e. their children. The survey of people in work corroborated by several case studies conducted in the

doctoral research stated very clearly that people were very aware of their MKSC even though they did not describe it as such. There can be little doubt that a learner's first requirement is the confidence in being able to know, without which, very little learning may be achieved. This is not about whether mathematics is more important than any other topic. Rather it offers a research-informed intervention that enables a limiting and mistaken self-perception to be exposed and dismissed.

There are several converging strands that compete to attest to the achievement of what are thought to be complementary outcomes. Learners have needs that are influenced by their interests, cultural background, career objectives and what they perceive to be their innate talent. Policy makers encourage and support the development of knowledge skills and competence for the benefit of society in the broader sense, while at the same time catering for the needs of industry by prescribing standards of quality and consistency. Practitioners and trainers devise curricula that comply with the terms of the national standards while at the same time appealing to and meeting the ambitions of the learners, insofar as they can be known in advance, and measured with reference to learning outcomes.

Employers operate in a more dynamic and fluid context that prioritises marketability, cost efficiency, competitiveness and profitability, but not fully conversant with the implications of the QQI-NFQ levels. The factors that drive these things are made volatile by the necessity to react to change in demand, technology, innovation and expectation. It is impossible, despite Government funded initiatives, to anticipate fully the sets of knowledge skills and competence that may become scarce within a few years and therein lies the kernel of the problem. Educators must equip learners with the resources to perform in an environment that is undergoing constant change. This must be done in compliance with a programme that has been in gestation for two years prior to being implemented in a four year degree programme. A person in employment for that same six years will have acquired a profound understanding of the workplace and its requirements, albeit specific to and probably contained by that workplace.

The process outlined in this paper and the accompanying tools enable individuals to highlight what they 'know' as distinct from what they 'do' to establish the confidence in learners that they are capable of 'knowing' whatever they choose, especially mathematics. It provides a platform from which people can embrace their knowing for the benefit of their employability and re-employability to meet the challenges of the emerging and exhilarating new World of the 21<sup>st</sup> Century. The interventions described herein have emerged from the finding of, and reflection on, the preceding research work. They have been introduced in real, adult learner situations with very promising results.

The authors would like to acknowledge the contribution of Ciarán O'Sullivan, Applied Mathematician, TU Dublin, for his invaluable insights into how best to present the process and associated tools in a way that would be more easily accessible to practitioners.

Site Code: A Job: 1.1Warehouse Picker						
	Insert Job Description here	Pattern & Relationship	Quantity & Number	Space & Shape	Data handling & Chance	
	instructed by work orders and guided by handheld scanner, retrieve files and documents that have been stored amongst 3 million other documents. Locations are identified by an 8 digit barcode, files by a further 8 digits.					
Task no.	Boxes may also bear an owner provided identification number / barcode or text. Location codes are hierarchical by Building, Floor, Row, Bay and shelf. There are 3 buildings each with 3 or more floors, each floor has an access stairwell and is served by a centrally located goods lift. Each floor has up to 52 rows, each with 26 bays, each bay has a series of numbered columns of shelves on 3 levels, A,B and C at the top. Example LEV118J10C means that the building is LEV, on floor 1, row 18, bay J, column 10, top shelf. There are also Vaults and Data storage locations on some floors. Work orders are customer specific. There may be more than 1 work order for a customer. Customers are assigned to delivery routes. The scanner is a representation of the work orders that have been assigned to the picker. The information on the scanner is presented in the order of the location code. However, this does not inform the picker as to the most efficient way or picking, because it does not take into account the load at each location, its proximity to access and egress, the lift, openings in the rows (one in the middle and (sometimes) one at each end, nor does it take account of whether it is more efficient to complete all rows on one side before crossing to the other. When a file is not found, the picker will look for it as thoroughly as the time allows, giving rise to the NF category of CBA (couldn't be ar***d).

## Numeracy practices in older age

*Demographic changes render basic skills important at an increasingly older age. Among them, skills in financial matters are becoming increasingly relevant. The skills measured in PIAAC and CiLL represent comprehensive cognitive abilities that can be seen as the basis for successful participation in social and economic life. In a secondary analysis, this paper shows that financial practices remain important for older people, although their numeracy skills proficiency appears to be lower than those of younger people. The analysis also indicates a gender difference in dealing with financial matters: men handle bills and bank statements, women manage the household.*

**Keywords:** Numeracy, practices, older adults, PIAAC, large-scale assessment.

### Introduction

As a result of demographic changes, it is becoming increasingly important to actively shape one's life in a longer post-employment period (Kruse 2008). Financial security and the ability to act have an ever-increasing importance in times of possible restrictions in income among the elderly. People who are low-skilled or whose employment biographies show gaps are more likely to be disadvantaged in this process (Wienberg & Czepek, 2011).

The question is whether the increased requirements become problematic due to higher financial burdens in older age, if they are accompanied by lower numeracy skills, or whether existing numeracy skills will prove to be sufficient. Instead of merely declaring a decrease of skills in relation to older age, the actual numeracy practices of people of higher age need to be more closely considered.

This article is dedicated to examine the numeracy skills of people of older age (66-80 years at the time of assessment) and their everyday numeracy practices. According to anthropologist Jean Lave (1988), mathematics is used in various situations in everyday life. This includes the comparison of prices, but also the calculation of costs and the household budget. PIAAC (Programme for the International Assessment of Adult Competencies) and CiLL (Competencies in Later Life) define numeracy as the ability to apply and interpret mathematical information and ideas to deal with different everyday situations (Zabal et al., 2013).

In this paper, data from the CiLL survey (Friebe, Schmidt-Hertha, & Tippelt, 2014) is used to compare numeracy practices of individuals aged 66 to 80 years with the practices of individuals aged 16 to 65 years as surveyed by PIAAC. The focus of the following secondary analysis is on practices (also referred to as skills-use variables) that provide information on how often numeracy skills are applied in the lives of older people.

## **Relevance of numeracy and financial skills in older age**

Images of older age have changed in Germany in recent years (Vogel & Motel-Klingebiel, 2013). The boundaries indicating who belongs to the older adults may not simply be determined on the basis of the calendar age. However, since PIAAC looked at people up until the age of 65 and CiLL assessed participants in the ages of 66 to 80, the integral boundary between these two surveys is used as a proxy to distinguish adults and older adults. Older people are thus in this paper the over 65-year-olds.

Medical and technical developments make an ever-increasing lifespan possible, thus creating a longer post-employment phase of life (Mahne, Wolff, Simonson, & Tesch-Römer, 2017). The aspect of financial security plays an important role for a good way of living in this post-employment period. In Germany, income in retirement is mainly determined by the statutory pension as well as by assets and inheritances. Therefore, people whose employment biographies show gaps or who had had low incomes are disadvantaged and in danger of poverty in older age. In addition, this group of people often inherited less frequently and accumulated less assets during their employment period (Mahne, Wolff, Simonson, & Tesch-Römer, 2017). In this respect, the proportion of people who have to work after retirement has increased (Franke & Wetzels, 2017). This raises the questions about how older people can get along with limited financial resources. Increasing financial skills in older age will not entail an increase of funds or pensions, but can help to manage low income successfully.

Referring to older people, Kruse describes competence as skills and abilities of the human being (Kruse, 2018, p. 1193) that contribute to the preservation as well as to the possible restoration of an independent, self-responsible and meaningful life. For older people there maybe a reduced ability with regard to orientation in new problem situations and new learning, but there is the necessary skill to solve familiar problems and to expand existing knowledge systems into old age (Kruse, 2008). As a result, it can be assumed that basic mathematical skills also contribute to solving financial tasks in everyday life.

According to Geiger, Forgasz, & Goos (2015) the financial competence can be seen as an extension of numeracy that is expressed in numeracy practices. From this perspective, a financially literate person must have both the necessary knowledge to carry out financial transactions and plans and the ability and confidence to make financial decisions (Geiger, Goos, & Forgasz, 2015).

The results of the CiLL study show that the average everyday mathematical competence of the population between 66 and 80 years of age is 240 points (Knauber & Weiß, 2014). This corresponds to the lower third of competence level 2 and indicates that on average older people are capable of dealing with mathematical information embedded in everyday contexts, solving everyday mathematical tasks with little competing information and processing steps (Knauber & Weiß, 2014).

Nevertheless, in adult education research in Germany, financial literacy is discussed more frequently than numeracy. Mania and Tröster (2014) describe financial literacy as a sub-area that concerns the existentially basal and practical demands of everyday life and lifestyle in monetary matters (Mania & Tröster, 2014). They developed a competence model describing the requirements

for dealing with money at the level of basic education. The model covers six domains of basic financial education (income, money and payments, spending and buying, households, lending and borrowing, pensions and insurance). Thus they can make an important qualitative contribution to the discourse. Representative results in the field of financial literacy are still lacking. Our study refers to the numeracy aspect of financial literacy in order to explain the financial capacity of older people to act.

## **Research questions**

Starting from a position that skills are complemented by practices, the focus of this contribution is on numeracy practices of older adults (66-80 years). Accordingly, the overarching question is how numeracy practices are used in older age and whether they help people to be financially capable.

In particular, the following questions are addressed:

- a) How do numeracy skills work with increasing age?
- b) How do numeracy practices work with increasing age?
- c) How do numeracy practices change according to gender at the ages of 66 to 80?

## **Methods**

The data from the PIAAC survey and the supplementary survey CiLL can provide a differentiated picture of numeracy skills and practices for the German population. The representative survey PIAAC was initiated by the OECD, and it was conducted for the first time in 2011/2012 and reached a sample of 5,465 persons aged between 16 and 65 years in Germany. In addition to the survey of the domains literacy, numeracy and problem solving in technology-rich environments, questions on the use of skills were asked in an extensive questionnaire. The subsequent supplementary survey CiLL used the same background questionnaire and the skills were measured in the same way as in PIAAC. This enables a comparison of these two surveys (e.g. Schmidt-Hertha 2018). The representative sample of 1,339 persons aged between 66 and 80 years was conducted in Germany in 2012 (Friebe et al., 2014). In both surveys, twelve questions on work- and non-work-related practices were asked. We are looking at post-employment phases, only the questions that are not work-related are relevant for this research.

### **Numeracy skills for different birth cohorts**

First, the numeracy skills for persons between 16 and 65 years and between 66 and 80 years were evaluated. It should be noted, that ages in PIAAC and CiLL are derived from the indicated birth year. Comparisons between age groups are therefore not statements on an individual decline in competence over the lifespan but statements on differences between groups in the birth cohorts. The mean skill values for numeracy indicate a decrease for both men and women for the older birth cohorts.

When comparing the data of the two birth cohorts 16 to 65 and 66 to 80 year olds, men in the older groups score almost 50 skill points lower and women almost 60. For both groups these are differences equivalent to one whole skill level (men level 3 to level 2; women level 2 to level 1) and indicate that women on average tend to do the simplest calculations. The differences may point to

an historical effect, especially for the oldest cohort. Those who are born between 1931 and 1936 often have had interrupted educational careers and different social and cultural expectations to those of the younger cohort.

The average skill value of the entire CiLL cohort (66-80 years) is 240 points, which is below the average skill value of the entire PIAAC cohort (16-65 years) of 272 points.

**Figure 1: Numeracy skills average for the PIAAC Germany (N=5,379) and CiLL (N=1,338) samples compared**

**Figure 2: Average of skills-use variables for the German PIAAC (N >5,000) and CiLL (N >1,200) sample comparison**

The next step is to check how the skills-use variables (indices) of the two samples differ. In order to assess how the practices are used in general, the analysis took into account the skills-use variables

of literacy skills (frequency of reading and writing in everyday life). For all everyday practices, a decreasing frequency of use across age groups can be observed (see Figure 2). However, this development is not comparable to the skills variable described above. For numeracy, there is a small increase in the average frequency of use from the 55-65 age group to the 66-70 age group.

### Numeracy practices in older age

Based on practices to be considered in the context of the social and economic system, the variable H\_Q03b (Calculation of prices, costs and budgets)<sup>1</sup> is divided by gender. There is a highly significant difference between men and women in the application of simple numeracy skills: 42.3% of men said they used calculation of prices, costs and budgets at least once a week or daily, while 58.8% of women gave the same answer (see Figure 3). 20.3% of men said they "never" used the practices. Among women, 16% said they "never" calculate prices, costs and budgets.

It shows overall both groups frequently used the practices, but women use them significantly (level of significance below 0.01) more than men do.

**Figure 3: Frequency of calculating prices, costs and budgets by gender in the CiLL sample (N=1,338)**

The variable that asks for the reading frequency of bills or bank statements (H\_Q01g, see Figure 4)<sup>2</sup> reveals that men say they use this practice more frequently. 51.2% said they read bills or bank statements at least once a week, while 42.9% of women gave the same answer.

<sup>1</sup> Background questionnaire H\_Q01b: "In your everyday life, how often do you normally calculate prices, costs or budgets?"

<sup>2</sup> Background questionnaire H\_Q01g: "In your everyday life, how often do you usually read bills, bank statements or the similar?"

**Figure 4: Frequency of reading bills and bank statements by gender in the CiLL sample (N=1,338)**

## Discussion

We see that the variables on the use of skills recorded in PIAAC and CiLL can provide some information on the frequency in which the skills required for financial decisions are applied.

### a) How do numeracy skills work with increasing age?

Despite a lower average skill proficiency in older age groups, numeracy practices are still regularly used. This should enable them to act financially for themselves. After a peak in the age cohorts of 25 to 34 year-old women and 35 to 44 year-old men, the mean skill values are steadily declining. This finding reinforces the results on the course of numeracy skills in PIAAC (Maehler et al., 2013) and in CiLL (Knauber and Weiß 2014; Gebrande & Setzer, 2014), which have only been reported separately so far.

### b) How do numeracy practices work with increasing age?

The comparison shows that the mean values of the skill-use indices for numeracy between the age groups 55 to 65 and 66 to 70 increase slightly. This could also indicate that the transition to the post-employment phase is accompanied by an increase in the use of numeracy practices. Such as dealing with pensions, paying of mortgages or applying for new state benefits.

Similar to reading and writing practices, a decrease in numeracy practices can be observed with increasing age, with reading overall remaining at a higher level. However, changes in skill-use remain marginal compared to the differences of skills.

### c) How do numeracy practices behave according to gender between the ages of 66 and 80?

The index of numeracy practices, consisting of six questions, was further analysed, these included the handling of budgets and prices as well as the handling of decimal and percentage values, which

increased. Another variable is used from the index of reading practices, which concerns the reading of bills and bank statements. The results show that 58.8% of women perform simple calculations weekly to daily. Only 42.3% of men do this weekly or daily.

It can be assumed that women manage household budgets weekly and are apparently more often confronted with numeracy practices than men are. The handling of bank statements and bills per week less frequent for men in the 65 to 80 age group. It remains to be examined whether this distribution will change for in the now younger cohorts or whether it is essentially due to a still classical distribution of household chores (c.f. Hobler, Klenner, Pfahl, Sopp, & Wagner, 2017).

Overall, it can be seen that numeracy practices in the area of "calculating prices, costs and budgets" are still used at least once a week by about 42% of men and more than half of women (59%) despite their older age. Having lower skills could make these activities more difficult, but at the same time qualitative studies that this older age group also show a considerable range of numeracy practices (card games, mental arithmetic, payroll tax, photography/development, club treasury, cf. Knauber & Weiß, 2014).

Numeracy practices could guarantee self-confidence in everyday life and in socio-political judgements to a certain extent, because "being numerate is being critical" (Tout, 1997).

## How theories of language-responsive mathematics can inform teaching designs for vocational mathematics

Lena Wessel

University of Education Freiburg, Germany; [lena.wessel@ph-freiburg.de](mailto:lena.wessel@ph-freiburg.de)

*This paper gives an overview of an Erasmus+ project that aims at empirically identifying the potentials and challenges of language-responsive teaching designs for low-achieving students in vocational contexts by means of topic-specific design research. It delivers first insights into developing and experimenting with two teaching units (percentages and proportional reasoning) and summarizes the questions that come up when adapting design principles for language-responsive mathematics teaching for the teaching and learning of young adults in vocational education. The empirical investigations are carried out with young adult pre-apprentices in lower vocational education in Germany in the technical sector. These young adults are often low achievers in mathematics and often have only limited language proficiency in the language of instruction.*

*Keywords: Vocational education, language, percentages, scaffolding, design research.*

### **Theoretical background for designing teaching-learning arrangements in vocational settings**

Legitimization and justification for further developing mathematical literacy in vocational education to a certain degree, amongst others, lies in the utility of mathematics in the workplace. However, we can draw on empirical research gained in different vocational sectors showing that the workplace mathematical practices often differ from school mathematical practices (Noss, Hoyles, & Pozzi, 2000). With reference to Noss et al. (2000), LaCroix (2014) summarizes that

it is recognized that mathematics practices in the workplace are shaped by the immediate and practical requirements of workplace production; that is, getting particular tasks accomplished with ease and efficiency using resources at hand rather than the goals and norms of generality, formality, and internal consistency commonly associated with school mathematics. (LaCroix, 2014, p. 159)

These differences can serve as an important starting point for joint reflection in vocational mathematics classrooms so that the mathematics teaching and learning is meaningful for the students. When it comes to designing teaching and learning arrangements for mathematics in vocational education, a further important aspect, which can be perceived as a challenge as well as a resource, is the huge variety of vocational sectors in which students are accomplishing their vocational education and which lead to many differences in the way that students meet the mathematical demands, since the mathematical demands on the job are not only topic specific, but especially also vocation specific (for an overview of vocation-specific research see LaCroix, 2014, p. 159).

Many students are mathematically unprepared to face the demands of vocational education or vocational training (Hoyles, Noss, Kent, & Bakker, 2010). While mathematical literacy is important

for meeting these demands, PISA results for Germany show that 17.2 % of the middle school students cannot rely on sufficient mathematical competencies to continue education in an apprenticeship training position. As a consequence, many German students (mostly aged 16-22) continue schooling at vocational schools as pre-apprentices and enroll in classes to obtain a middle school degree.

Besides experiencing difficulties in test situations, students with low language proficiency experience difficulties in the learning situations themselves. This relates to the role of language as a learning medium in classrooms: Language in mathematics classrooms is at the same time a medium of knowledge transfer and discussion and a tool for thinking (*communicative* role of language vs. *epistemic* role of language, Pimm, 1987). Taking both roles of language into account, research in mathematics education repeatedly emphasizes the intertwining of language and mathematical thinking for all students, but especially for students still acquiring the language of instruction (e.g., Moschkovich, 2015). As a consequence, current design research studies in primary and secondary mathematics education focus on developing and investigating content and language integrated instructional approaches for fostering students with low language proficiency (e.g. Prediger & Wessel, 2013). Theoretical and empirical approaches are pursued to postulate design principles for intertwining conceptual and language learning trajectories, while language unfolds into the different levels e.g. the lexical and discursive level of language (Pöhler & Prediger, 2015; Wessel & Erath, 2018).

With respect to vocational education, the importance of language proficiency for successfully meeting the demands of the workplace is also well recognized, especially from the perspective of general didactics and more general vocational pedagogy (compared to vocational *mathematics* education research) (Ziegler, 2016). Specific vocational language demands - such as the discursive demand of counseling situations in communication with customers - are identified. On the lexical level, challenges are often traced back to the specific vocabulary relevant and needed in a specific profession or vocational sector.

However, an analysis of language demands only ‘on the job’ is too restrictive and shortsighted, because students are already confronted with vocation-specific language demands in workplace-related mathematics teaching and learning situations. In mathematical learning processes, language plays an important role in an epistemic role for developing students’ understanding of mathematical concepts. Thus, in intended learning trajectories in which linguistic and mathematical learning trajectories are intertwined also the vocation-specific language demands have to be taken into account.

When aiming at unfolding the relation of language, especially vocation-specific language and corresponding language demands, and mathematics embedded in workplace settings, one recognizes and has to admit an enormous complexity along with a lack of theoretical approaches to acknowledge this complexity. Thus, this research wants to contribute to theorizing the complex relation with respect to topic-specific vocabulary and discourse practices as learning opportunities for deeper mathematics learning.

## Research and task design gap

Empirical research on language-responsive teaching and learning of mathematics for the primary and secondary school levels is still relatively young; however, important theoretical considerations by now are more than 30 years old (Pimm, 1987) and there is a constantly growing and consolidating theoretical foundation from mathematics education and linguistic theory to be drawn on in design research projects. At the same time, the practical realization of well-defined design principles in content and language integrated approaches is topic-specific (e.g. language for understanding *percentages* differs to a certain extent from language for *understanding functions*) and there is still a huge lack of research which aims at systematically specifying the topic-specific language demands for the different mathematical topics.

When it comes to vocational teaching and learning of mathematics, the aspect of language in vocational mathematics learning processes is at the moment not that much in focus as it is in primary and secondary mathematics education; however, aspects of language are implicitly touched due to the deep connection of language and the theoretical approaches (like webbing and boundary crossing) being pursued. Still, like language-responsive teaching designs are always topic-specific, recent insights into content and language integrated teaching can neither simply, nor entirely be transferred to vocational settings (just to mention age, previous experiences with mathematics in middle school, the often described very huge heterogeneity, the case of remedial learning, (mathematical) practices of and at the workplace, the many different vocational sectors etc. as a small selection of the changing surroundings that must be taken into account).

That is why there is an urgent need for empirical qualitative and quantitative research that carefully investigates the situative effects and potentials of language-responsive vocational mathematics teaching and learning. We hereby rely on the notion of language-responsiveness as mathematics teaching that accounts for and is sensitive to multiple languages (which, amongst others, can be conceptualized as different national languages, different language registers, or non-verbal semiotic means) in order to enhance deeper understanding of mathematics (sometimes different terms like “language-sensitive mathematics” or “content- and language integrated teaching” are used, see Wessel & Prediger, 2013 for further elaboration).

## Research questions

For minimizing the above described design and research gap, in this paper vocational-specific resources and differences when extending the approach of language-responsive mathematics to vocational mathematics education are pursued. Thus, the paper aims at answering the following research question: Which differences can be identified when consolidated design principles for language-responsive mathematics teaching for middle school teaching are adapted to lower strands of vocational education?

## Research context and methodological framework

The project “*Language for Mathematics in Vocational contexts*” is an Erasmus+ funded research project in which mathematics education researchers collaborate with teachers from vocational schools from Germany, the Netherlands, and Sweden. The team develops empirically consolidated

language-responsive mathematics teaching units for the mathematical fields ‘understanding percentages’, ‘proportional reasoning’, and ‘understanding diagrams and graphs’ for vocational education of pre-apprentices as well as professional development modules for mathematics teachers at vocational schools. For this paper, the focus will be on the classroom level. The developmental work on the classroom level concentrates on those strands of vocational education for young adults who are not yet in an apprenticeship training position, but aim at completion of a middle school degree. The mathematical foci were chosen because of their importance for the target group, and because the researchers already gained experiences with developing language-responsive teaching material for these topics in secondary school classrooms.

The young adults (16-22y) in the German part of the project often did not yet successfully develop the main mathematical concepts and are often not yet fully fluent in applying the main procedures which are in the fore of the middle school mathematics curriculum. Consequently, the teaching units take into account design principles for remedial learning. In addition to that, the young adults enrolled in these strands of vocational education also belong to the group of vulnerable students with respect to language proficiency.

The research is conducted in the methodological framework of topic-specific didactical design research (Prediger & Zwetzscher, 2013) in which the analysis of teaching-learning processes takes place in carefully designed teaching experiments. Design experiments are considered the methodological core of design research studies as they allow in-depth investigations of learning *processes* rather than only learning *outcomes* (Gravemeijer & Cobb 2006). They serve as means of data gathering for qualitative in-depth analyses of the young adults’ learning processes.

The design experiments are video-taped and conducted in small-group or partner design experiments as well as whole-class teaching experiments. The video data is analyzed qualitatively with well-proven language activation categories of our previous research which is combined with inductive development of categories. All whole-class teaching experiments are carefully planned in each national team of researchers and teachers, e.g. in the here reported German team of two mathematics education researchers and seven teachers from three partner vocational schools. Furthermore, the researchers draw on classroom observations and field notes from all whole-class teaching experiments and subsequent discussions on what works well and does not work well.

Throughout the project and for the different mathematical topics being investigated, specifying and structuring the learning trajectories differs due to the different disposability of previous research. In the first year (Sept. 2017 - Sept. 2018) and for the teaching unit ‘percentages’, the developmental work relies on a consolidated intertwining of conceptual and lexical-discursive learning opportunities (Pöhler & Prediger, 2015; Pöhler, 2018) for middle school teaching that is being adapted. The following results and conclusions for the raised research questions rely on the adaptation process of the teaching unit ‘percentages’ and draw on teachers’ and researchers’ observations and field notes from six vocational classes in which the adaptations of the teaching unit have been used in the academic school year 2017/18. The teaching unit was taught over 4-5 lessons of 90 min. each in each of the classes and video-data for at least one lesson per class was gathered.

## First conclusions from adapting a language-responsive teaching unit

In order to understand the changes that have been identified as important when adapting a language-responsive teaching unit for vocational classes of a lower strand of vocational education, the next paragraph gives an overview of important design principles for language-responsive mathematics teaching and which have been realized in the teaching unit designed and empirically investigated by Pöhler (2018).

### Design principles for language-responsive mathematics teaching and learning

*Design principle “Macro-scaffolding by intertwining language and conceptual learning trajectories”.* The general structure of intended language learning trajectories is well described in the principles of *macro-scaffolding*, namely from students’ everyday resources to academic and formal technical registers (Gibbons, 2002). For their developmental work, Pöhler and Prediger (2015) connect the level principle from *Realistic Mathematics Education* for conceptual learning trajectories with macro-scaffolding of language. According to the level principle, a hypothetical learning trajectory is to be sequenced over four levels of increasing deepness of understanding (from the situational level to the referential level, to the general level, to the formal level) (Gravemeijer, 1998).

Levels	Conceptual learning trajectory: Mathematical conceptions	Lexical learning trajectory through different vocabularies
Level 1: Informal thinking starting from students’ resources	Constructing meaning for percents by representing and estimating rates	Intuitive use of students’ resources in everyday register, no offer of new lexical means
Level 2: Informal strategies and meaning-related vocabulary	Developing informal strategies for determining rates, amounts and later bases	Establish basic meaning-related vocabulary in the academic school register for constructing meaning for rates, amounts, bases in context
Level 3: Procedures for standard problem types	Calculating amounts, rates and later bases	Introduce formal vocabulary in the technical register
Level 4: Extending the repertoire	Widening to other problem types: change and comparison	Enrich the basic meaning-related vocabulary to more complex problem types
Level 5: Identification of different problem types	Identifying problem types of (non-) standard problems (in diverse contexts)	Explicit use and training of formal and basic meaning-related vocabulary
Level 6: Flexible use of concepts and strategies	Cracking more complex context problems flexibly (in non-familiar contexts)	Introduce extended reading vocabulary for various non-familiar contexts

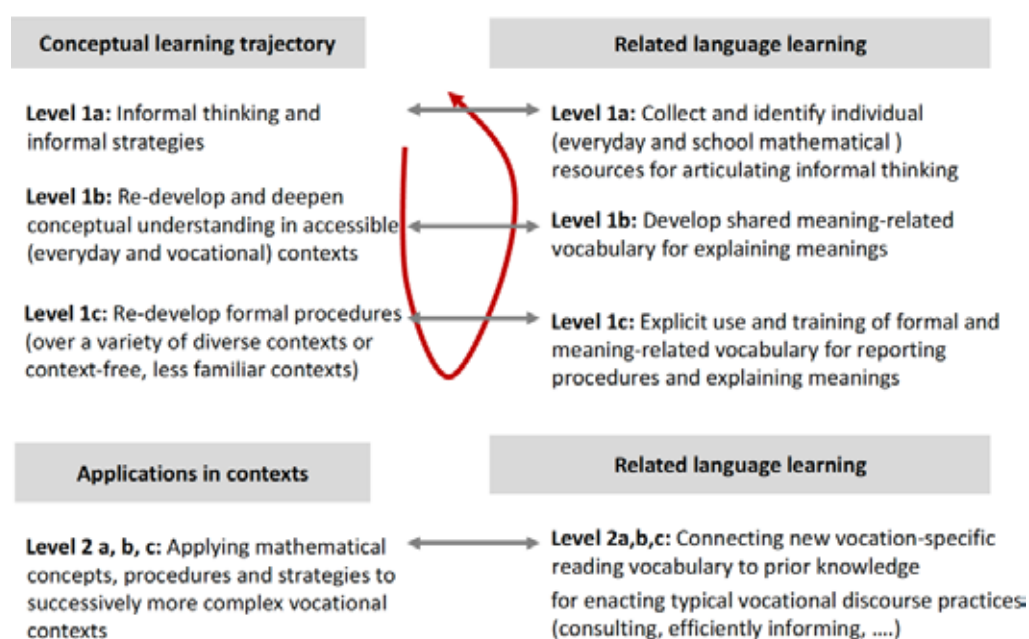

**Figure 1: Combining conceptual and lexical learning trajectories – macro-scaffolding example for percentages (Pöhler & Prediger, 2015)**

By intertwining the two dimensions of sequencing (conceptual dimension and lexical dimension), Pöhler and Prediger (2015) develop the dual learning trajectory towards understanding percentages depicted in Figure 1: The conceptual learning trajectory is sequenced in six steps starting from students’ resources in informal thinking to informal strategies, formal procedures and their flexible use. Each step requires other discourse practices and different vocabularies which are sequenced in the lexical learning trajectory (Fig. 1 on the right).

On the lexical learning trajectory, the teaching unit starts from the students’ individual language resources (level 1) and the basic meaning-related vocabulary. These lexical means from our vocabulary are especially important for explaining the meaning of concepts: meaning-related vocabulary grasps mathematical relations and meanings (e.g., *take away* for the meaning of subtraction). It usually belongs to the academic school register and should be introduced before

formal vocabulary (Wessel, 2015) (see level 3 where introduction of formal vocabulary begins). Empirical evidence has been given that this intertwinement can be effective for mathematics learning (Pöhler & Prediger, 2015).

For pursuing the research question “Which differences can be identified when consolidated design principles for language-responsive teaching for middle school teaching are adapted to lower strands of vocational education?”, the focus is put on the design principle *Macro-scaffolding by intertwining lexical and conceptual learning trajectories*. Figure 2 depicts the adapted combined learning trajectory for the teaching unit percentages for vocational education. Reasons for how the adaptations have been made are (amongst others) explained in the following.

**Figure 2: Adapted combined conceptual and lexical learning trajectory for workplace-related teaching and learning of percentages**

In the case of lower vocational strands in which the research is conducted, teachers only have little teaching time for remedial learning of percentages and the young adults have prior knowledge from their middle school teaching. That is why the learning trajectory has been condensed to two levels in each dimension. The transition to workplace-related, vocational contexts is implemented in level 2, which means that on purpose the re-activation of understanding percentages happens in familiar, everyday contexts (shopping, downloads). Consistently, the vocation-specific language is accounted for on level 2 in the language learning trajectory.

### Insights from teaching experiments with the adapted teaching unit and conclusions

When conducting and reflecting on the teaching experiments with the adapted percentages tasks, two main insights have been gained with respect to the design principle under investigation and task design.

Firstly, the young adults already know percentages, to some extent some calculation procedures, and percent-specific language like the formal (more technical) vocabulary, so that they can recall on

this knowledge. However, we experience many instances in which procedures are carried out without understanding, as well as instances in which the formal vocabulary is not filled with adequate meaning. As a consequence, the formal vocabulary can be used as starting point for raising students' awareness for the need to developing deeper conceptual understanding. Working on conceptual understanding of percentages builds on meaning-related vocabulary and reflecting on the different registers in carefully designed teaching activities. In a concrete task design, the vocational discursive demand of counseling was thus taken as a resource to initiate meta-reflections on language: In a language-responsive activity students are asked to translate a dialogue with customers given in very technical language into a more natural meaning-related form. We thus conclude that a further analysis of the authentic, vocation-specific discursive demands is promising, because they serve as meaningful situations to be drawn on in language-responsive teaching of workplace-related mathematics.

Secondly, it turned out that the levels 1a to 1c of the adapted learning trajectory in practical teaching are not realized as levels but resulted rather in a back- and forth between the three levels, both in the conceptual and in the language dimension. We hypothesize that this is also due to prior knowledge of percentages that the young adults have already acquired in their middle school mathematics. As a consequence, the question must be raised to which extent the design principle of sequenced learning trajectories is fruitful in those strands of vocational remedial education.

## Outlook

The above empirical insights led to the question which further design principles are relevant to make language-responsive teaching work fruitfully at vocational level. At the moment, the project team is working on this question and implements for example the principle "Accounting for high heterogeneity without neglecting rich communication". Thus, we account for the so far often referred to different conditions of lower vocational education compared to general middle schooling. In a next step, further research is conducted to analyze the hypotheses and raised questions concerning the implemented design principles as well as to identify the potentials and effects of language-responsive teaching in vocational contexts.

## Acknowledgment

The research project LaMaVoc ("Language for Mathematics in Vocational Contexts") is funded as an Erasmus+ grant by the National Agency BIBB from 2017-2020 (research grant KA202-004130). The author conducts this research together with Susanne Prediger, Patricia Epke, Monica Wijers, Vincent Jonker, Eva Noren and thanks them for their collaboration.

### **Introduction**

In this chapter, we would like to introduce discussions about the affective constructs and their relation to teaching and learning of mathematics. Before the conference, we agreed to change the title of TWG from “Affect and mathematical thinking” to “Affect and teaching and learning of mathematics”. The new title of the group better reflects the broad scope of research that we welcome in our group. All types of affective constructs that emerges in relation to both *learning* and *teaching* of mathematics could be represented and discussed in the working group during the conference.

The number of submissions and participants confirmed the interest of mathematics education researchers in affect. In total 26 papers and 3 posters were submitted to our group, with 24 papers and 2 posters were accepted for presentation, and 23 papers and 2 posters accepted for publication in these conference proceedings. Our group included presentations from Canada, Israel and different European countries. Participation of researchers from 15 countries (including 13 newcomers) reflected the spirit of inclusion that is traditional for this group that has been discussing affect in mathematics education in recent years.

We started our work with an introductory, ice-breaking activity and a reflection of the work done in previous conferences. This year we decided to considerably increase the time for discussions of each paper and structured the paper and poster presentations and discussions in a new way. After a short presentation (7 min) and clarifying questions (3 min) of papers that we scheduled within each session, authors of presentations discussed their research (30 – 40 min) with other group members in small groups. Participants could decide which paper or poster they would like to join for discussion. We assigned contributions to the sessions in groupings related to: affect; emotions; identity; beliefs; and motivation or attitudes/engagement. At the end of each session, we shared our thoughts about these topics with the whole group. In the final session, we discussed new perspectives on affect and related constructs that emerged during our work.

### **Reflection on prior research in affect**

Peter Liljedahl presented a comprehensive overview of the work that has been done during the past CERME conferences. Çiğdem Haser and Stanislaw Schukajlow picked up and elaborated on this

overview during the presentation of the report about the work of the TWG8. The starting point for systematic research on affect in mathematics education is usually a review paper by McLeod (1992). In his seminal work, the author introduced an influential taxonomy of affect. According to this taxonomy, affective constructs can be assigned to different points on the line that ranges between beliefs through attitudes to emotions. Beliefs were proposed to be most stable, less affective and most cognitive, whereas emotions were noted as less stable, most affective and less cognitive.

In the last decades, researchers underlined repeatedly that the complexity of affect requires elaborating the taxonomy proposed by McLeod. For example, Hannula (2012) analyzed research in mathematics education and suggested a need to distinguish between three dimensions as common foundations for a theoretical framework. These included: cognitive, motivational and affective dimensions; unstable states and stable traits; and social, psychological or physiological nature of affect.

Recently, object of the affect (affect about life, learning, problem solving or strategy use), subject (teacher or students) or valence (positive or negative) were suggested to be important for research on affect (Schukajlow, Rakoczy, & Pekrun, 2017). Further, the theoretical approach (acquisitionist or participationist) play an important role. Affective constructs that were explicitly anchored in the taxonomy by McLeod were investigated and new dimensions were proposed. For example, teacher beliefs about the nature of mathematics and their relation to learning can be assigned to beliefs about nature of mathematics, beliefs about mathematics teaching and beliefs about mathematics learning (Beswick, 2012). Teacher beliefs build a so-called belief system that start its development in the school years, changes in university years and is shaped based on the practical experience encountered by in-service teachers.

An important point raised in prior discussions related to the definitions used for characterization of affective constructs. As affective constructs are seen as complex phenomena the definitions of particular constructs often overlap with other affective constructs and are criticized as being circular. For example, emotions are defined as phenomena that included cognitive, affective, motivational, physiological and expressive parts. Affect and motivation are used in this definition thus for characterization and grounding of emotions.

Finally, reciprocal relationships between affective constructs and students' achievement is acknowledged and are crucial for understanding the role of the affect in teaching and learning. Most of the studies in the TWG8 targeted affect and implied problems with affective constructs as a reason for difficulties in teaching and learning. However, another perspective is also valuable, whereby students' or teachers' affective problems while learning or teaching might result from problematic achievements in the past.

## **Contributions in the TWG8**

In this section, we would like to present the papers that we included in these proceeding. Gómez-Chacón and Barbero investigated students' perception of backwards strategy in problem solving. Forbes et al. analyzed students' mindsets and its relation to self-confidence in programming. A low achiever's mathematical thinking was analyzed by Viitala in a case study.

Alcantara et al. explored students' failure experience and identified emotions hopeless, shame, frustration and fear. Relation between anxiety about generating drawings and students' gender, strategical and cognitive factors was analyzed by Schukajlow et al. Lake reported on the study that investigated how data about emotional state can be used during reflection on teachers practice.

An instrument for measurement of students' identity was developed and applied by O'Reilly et al. Narratives on student identity within a social-cultural environment were explored by Ben-Dor and Heyd-Metzuyanim. Howard et al. applied thematic topic analysis for research on students' identity and its relation to mathematics in higher education.

Figueiredo and Guimarães carried out a study on learning styles and their relation to performance. Van Hove et al. investigated students' mindset. An analysis of questionnaires for students' self-concept of mathematics in school and university was presented in the contribution by Rach et al. Westerhout et al. analyzed the effect of the project about game programming. The development and evaluation of the general and domain-specific scales for self-concept and interest were analyzed by Sproesser et al.

First-person vicarious experiences was found to be crucial for the change of beliefs by Rouleau et al. Pantziara et al. presented a study on validity of the scale about teachers' epistemic beliefs. Wiik and Vos reported on the study about reasons of choosing advanced mathematics courses in secondary school. Using metaphors for exploring pre-service teachers' beliefs was analyzed by Haser. Liljedahl presented an analysis of master and doctoral students' beliefs about research (Liljedahl, 2018).

Engagement in students' interactive storytelling and its impact on attitudes were explored in the contribution by Pierry et al. Novotna analyzed private supplementary tutoring and its relation to students' attitudes. Different levels of engagement (high and low) were distinguished in students with the same achievement level in the study by Skilling. Haataja et al. demonstrated that gazes at teachers' and at students' faces differed in small- and whole-group instructions. Kourty analyzed cognitive, behavioral and affective aspects of engagement in inquiry-based learning.

In posters, Hansen discussed collaborative processes while solving problems and Barton introduced a study on self-made tutorials.

## **Evolution of the TWG**

The overall quality of the submitted contributions increased and this resulted in acceptance of nearly all papers and posters for presentation at the conference. Contributions investigated affective measures of different subjects: primary and secondary school students, pre- and in-service teachers and doctoral students. Most of the researchers applied qualitative analysis and performed case studies, in order to answer their research questions. Thus, the distribution of submissions followed the general trend toward the dominating role of qualitative studies in research on affect (Schukajlow et al., 2017). One reason for this trend might be the efforts of researchers to capture the whole complexity of the affective phenomena and analyze it in relation to cognitive and strategical behavior. In our discussions about methodological issues, we pointed out that even researchers who applied qualitative methods should be aware that they can get only one "slice" of phenomena, even though it is usually more rich than in quantitative studies. On the other hand, researchers who applied quantitative analysis often

pretend to produce objective and valid results. In this type of analysis, limitations concerning operationalization and generalizing should be carefully addressed. The choice of research method should be derived not by general preferences of what is the “right” or “wrong” type of analysis, but by research questions that the researcher is interested in.

A new trend in the group was the appearance of several papers on identity. In their studies, researchers reported on how they assess identity and tried to understand this complex phenomenon. Assessment and theoretical background seem to be closely related to each other in research on identity. New theoretical approaches, such as theory of mindsets and theory of identity appeared in the papers this year. Further, we had again contributions that referred to psychological theories such as control-value theory of achievements emotions, theory of self-concept and other theories. Most of the studies investigated students affective state reflecting researchers’ interest in what is going on during learning. The new object of affective construct, emotions and perceptions regarding strategies used during problem solving, appeared for the first time in our group. Another trend is an investigation of the affect in learning environments that included programming as part of the treatment.

During our general discussion, Liljedahl summarized by using the scheme for assessment categories in research on affect (Table 1). Studies can address individuals or social variables (subject) within social or individual context. For example, if researchers investigated beliefs of individuals during group work, the subject is the individual and context is social.

		Subject	
		social	individual
Context	social		
	individual		

**Table 1: Assessment categories in research on affect**

*The article draws on preliminary results from a qualitative exploratory study on the emotions reported by students in relation to their experiences of school failure, particularly in mathematics. The research involves students at risk of failure in mathematics attending vocational secondary education in Brazil. As a theoretical approach, the attribution theory is interrelated with theory development in the study of emotions in mathematics education. When considering the hypothesis of distinguishing factors of failure between facilitators and inhibitors, we have identified in the students' verbal expressions several negative emotions that are tied to objects, agents and events of: the mathematics class, the mathematics as a discipline, and the mathematics assessment.*

*Keywords: Students' emotions, attributions, school failure, vocational education*

### Introduction

In Brazil, the Federal Institutes (FIs) offer young people a three-year training course that has the dual function of obtaining a professional qualification and simultaneously completing secondary education. The annual curriculum of vocational courses consists on average of seventeen subjects, twelve of them being part of the common national basis and five of a technical nature, totalling, on average, 36 classes per week. From the first year on, mathematics plays a central role, both because it is a subject of the secondary education common core and because it is strongly applied in the various technical disciplines. Although the FIs are generally viewed as schools that offer a quality education and contribute to better opportunities of access to an undergraduate course, the high failure rate in this subject results in a high dropout rate in this particular schooling system.

As part of a strategy for increasing the indices of permanence and success of the students in the IFs, the identification of students at risk became a priority. This entails knowing more about them, not only at the cognitive level, but also at the affective one, particularly with respect to mathematics.

Many studies have shown that school failure is not only due to cognitive aspects; the affective ones also play a very important role in the students' learning (Evans, Morgan, & Tsatsaroni, 2006). With this study we aim to understand how vocational secondary students experience situations of failure and poor achievement in mathematics that put them at risk of retention and/or evasion. Thus, the research has a focus on the student individual history with the discipline through capturing experiences failure in mathematics from an emotional point of view.

## **Theoretical background**

Research on the causes of school failure has a long history and has evolved through the contributions of various areas of knowledge given its complexity and multidimensionality. Broadly put, one may say that at least the cognitive (e.g. Rösken, Hannula, Pehkonen, Kaasila & Laine, 2007), the affective (e.g. Gomez-Chacón, 2003; Di Martino & Zan, 2013), and the socio-cultural perspectives (e.g. Lerman & Tsatsaroni, 1998; Heyd-Metzuyanim, 2013) have been called for the understanding of school failure.

There are two major ways of conceptualizing school failure, which imply different approaches to its study. Seen as a product, failure is the result of a judgment made by the agents of the educational system on the distance of the students in relation to the prevailing norms of school excellence. Those who meet the standards and advance in grades-based and retention-based courses will be successful. Failure, in turn, is determined by the poor academic performance of the students, who for various reasons are not been able to reach the competencies expected in a given period of time. Seen as a process, critical moments of developing failure involve low achievement, retention, school avoidance and dropout, and non-adaptation to the workplace (Dupéré et al. 2015).

School failure can be analyzed through deterministic variables and, in that case, it is described by disapproval, retention, and dropout in quantitative terms; it can also be approached through individual and social events that are more difficult to capture and in, that case, it is expressed in qualitative terms, such as individual frustrations, inadequate preparation, and alienation from democratic participation. Many symptoms of failure, which are usually veiled and not quantified, but constitutive of school failure (Nardi & Steward, 2003) are revealed in particular ways, such as: the student does not feel she/he belongs in school and does not like the school, refuses the pedagogical relationship, is aggressive and disengaged, and alienates from the school environment.

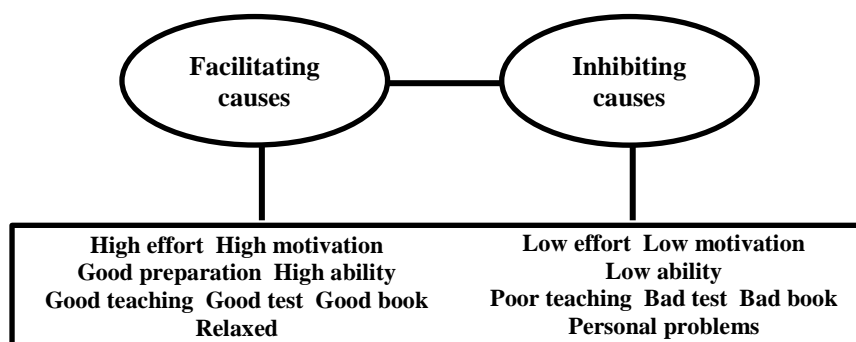

### **Attributional dimensions in students' failure**

Attribution theory is one of the well-known approaches to the study of the causes of school failure. It is based on getting individuals' perceptions about the factors that best explain the situations they live in and the states they go through. Studies aimed at determining the causal attributions of academic failure are abundant, both in the field of cognitive psychology and in the various domains of education (Almeida, Miranda, & Guisande, 2008).

Most of the studies carried out under this perspective assume that students are able to produce a conceptual framework that explains the causes of their results and, in particular, their failures in school. Moreover, this implicit theory can be seen as composed of unitary causes that are organized according to dimensions, which can be seen as the critical causes of academic performance.

Drawing on the work of Weiner (1985), causal attributions can fit into three commonly accepted global categories: internal and external causes (i.e. inside and outside the person); stable and unstable causes (i.e. remaining relatively constant or changing over time); and, finally, controllable and uncontrollable causes (i.e. under control or out of control of the will of the subject). More recently, Forsyth, Story, Kelley & McMillan (2009) have reexamined and reframed some of the findings of previous research studies by using a phenomenological approach. They asked college students right

after receiving their grades in a course exam about the factors that led them to get the grade they did. The researchers hypothesized that the causes would be structured in a hierarchical fashion but admitted that, as other studies have shown, some might not be mutually exclusive. The results show that the causes of failure emerged from a practical thinking that renders two broad categories: facilitators and inhibitors of success. This suggested placing the causes of failure in predominantly one-dimensional terms, where the bad-good, or high-low polarity seems to fit within the range between facilitating factors and inhibiting factors. The following diagram (Figure 1) illustrates the condensed causal attributions, which may not be exclusively in one side of the scale.

**Figure 1: Model of attributions (adapted from Forsyth, Story, Kelley & McMillan, 2009)**

According to the authors, several specific factors can be assigned to explaining failure; all those unitary causes are linked by a common attributional dimension: inhibitory factors.

Attributional thought can thus be considered to be a special case of a hierarchically organized schema, with a small number of global factors or dimensions subsuming a relatively greater number of more specific causal factors (Forsyth, Story, Kelley & McMillan (2009, p. 171).

Our research brings this theoretical view as a background and seeks to complement it with a theoretical view of emotion, according to which emotions or emotional states are expressible by individuals as ways of proposing their understanding of failure situations to others.

### **Emotions in students' interpretation of failure**

Several researchers have already embraced the construct of emotion as a dynamic system, where emotion cannot be seen as either the origin or the end point of a causal relationship between affect and performance. In her work, Gomez-Chacón (2003) has discussed the interplay between affect and learning as a cyclical process. On the one hand, the experience of learning mathematics provokes different reactions in the student and acts on his/her beliefs; on the other hand, sustained beliefs have a direct consequence on the student's behavior in learning situations and ability to learn. Similarly, in his review of the research literature linking emotions and mathematics, Xolocotzin (2017) has found some investment on the study of emotions as predictors and outcomes.

Di Martino and Zan (2011) have suggested a way of distinguishing emotions in terms of reactions to: i) Objects: a class of emotions that are linked to objects (attraction emotions) and refer to all variations of the affective reactions of liking and disliking (like love and hate); ii) Events: a class of affective reactions that relate to being pleased and displeased, consistent with the perceived consequences of an event as being desirable or undesirable (like joy, hope, fear) and, iii) Agents: a class of affective

reactions of approving and disapproving (like shame, admiration, reproach). These three kinds of emotions also differ with respect to the factors that influence them: attraction emotions are influenced by the subject's tastes; affective reactions of being pleased and displeased are influenced by the subject's goals; and affective reactions of approving and disapproving are influenced by the subject's beliefs and values.

Based on these theoretical assumptions, our research aim is to understand the emotions revealed by students in a situation of failure and how these emotions connect with the causes that they attribute to their failure.

### **Methodological considerations**

Given the subjectivity of emotions, in this preliminary study, we chose to give the students the opportunity to speak about what they consider decisive in their own experience of failure and poor achievement in mathematics, through a focus group interview. The qualitative study of emotions requires instruments consistent with an interpretative approach, capable of capturing students' emotions (Di Martino & Zan, 2013). Although revealing emotions when in a situation of failure may be difficult to individuals, we believe that a conversation among several students having failure in common may be a facilitator element, as also suggested by Martínez-Sierra (2015).

The conversation sought, in a first phase, to know the reasons that led the students to choose the courses they attended and their perspectives for the future. Next, we sought to hear the students about their relationship with mathematics throughout their schooling and, in particular, on their first year at the IFMT. Another leading question was: What emotions do you experience about mathematics and how are they affecting your relationship with other disciplines? This issue led students to talk about their emotions they experienced, namely during classes and assessment situations. Finally, the students were invited to comment on the remedial opportunities at the IFMT.

The group included 13 students (7 females and 6 males) who attended the first year of a vocational course at the Instituto Federal do Mato Grosso (IFMT) and are at risk of retention and/or evasion. The students accepted to participate in the focus group that took place after the academic activities and lasted approximately 1 hour. Their parents were previously informed of this interview, as part of the ongoing research, and consent forms were obtained, by guaranteeing anonymity and confidentiality of the data. The interview was conducted by the first author and audio-recorded.

Due to space limitations, we selected the voices of four students whose reports allow a sufficient reduction of the data in order to illustrate the emotions shared by the group during the initial conversation. From the data, we extracted some key elements that allow a brief presentation and characterization of those four subjects, as follows.

Ana is 15 years old; she is very talkative and effusive. She looks for all the help that is offered by the IFMT. Ana intends to take a higher degree. Carlos is 17 years old, is very shy and rarely interacts with the other classmates. He is repeating the 1st year and is still failing in most subjects. Amanda is 15 years old and reserved. She reveals some difficulties but not always attends the remedial classes. Bruna is 15, a very shy student but always with a smile. Her father supports her choice of electro-mechanics. She believes that her future will improve from studying at the IFMT.

The data analysis followed an interpretative process of content analysis based on two combined targets: i) Students' verbalised emotions in referring to failure; and ii) Verbalised indicators of causal attributions, linked to such emotions. Such indicators were later condensed and labelled as instances of inhibiting factors (emphasized in italics below).

## Results

### Emotions related to the mathematics class

The mathematics class was shown to be a source of events generating various emotions. For these students mathematics classes are monotonous and boring. The classroom environment is described as uninspiring and conducive to deprived concentration, inattention, and disinterest for the learning of mathematics. Boredom is one of the emotions portrayed in students' words. It is related to *poor teaching*, *bad atmosphere*, and *high confusion*. Boredom is linked to failing in following the class and in understanding the lesson and to feeling lost. As such, hopelessness is also an emotion that arises from their words.

- Ana: Boring! Always! Somehow monotonous, it's always: going to school, sitting down, listening to the teacher talking, working out some activities.
- Carlos: Everything distracts me. The mess in the classroom... Last year, for example... I did not understand anything.
- Carlos: When the teacher is explaining, my head is flying ... We feel that a lesson is boring when we cannot reason correctly.
- Ana: Then, you go to class... Like what he said, you can understand but at the same time, you cannot. It's like when you're reading a book, and your head for a millisecond flies... and then, you look at the book and think: What's this? Where did I stop? What was I reading?

Classes are also generating emotions related to agents. Schoolmates correspond to sources of shame and frustration for some students, who are in failure. Bruna reports that the classes generate displeasure, a fear of being censured, and shame for feeling inferior. The stare of her classmates is seen as reproachful by the student, who seems to value negatively her inability to understand what others apparently find easy. The student does not ask questions and gives up seeking support. Thus, she holds herself in silence and turns to the remedial classes for greater safety so as to be able to expose her difficulties, which she sees as a weakness of her. So, shame, frustration and fear are tied to *high censure* from classmates and to *low safety*.

- Bruna: I'm ashamed to ask. If I don't understand, I don't ask. Because at my side there are people who know, and if I say: 'Ah, Teacher, I didn't understand', they stare at me. So, I won't ask. The teacher is explaining and sometimes the teacher asks: 'Do you understand?' In my head, I think: 'No, I don't understand'. But, I say: 'Yes, I understood, Teacher'.
- Bruna: In the tutorial classes, I feel more at ease to ask the teacher what I can't understand.

Ana: Then you see your classmates talking, laughing... those little jokes: ah, you're smart, ah you're dumb... but you just couldn't understand... The teacher has explained a few times but people wouldn't be quiet! So, you couldn't pay attention.

Amanda: In my opinion, this is what happens: you have that hope, I mean, the teacher is explaining the content and then you think you'll understand it. Then he gives a task, he will present the resolution and... mine wasn't right. You get... like... discouraged.

The comments of schoolmates provoke reactions of shame and also of hurt because these students apparently feel that their schoolmates do not understand their difficulties. The comments made provoke humiliation that leads to a need of quieting them. Discouragement is another emotional reaction in these young people. After the hope of understanding a new content comes the disappointment for not being able to properly solve the task proposed. In brief, shame, frustration, fear and discouragement go hand in hand with *low sympathy* but also with *poor ability* in new tasks.

### **Emotions associated with mathematics**

Regarding mathematics, the reactions of these students are ruled by dislike. They react to that as a more difficult discipline than the others and recognize the weight it has in the other areas of the technical component of their courses. Thus, another associated reaction that can be identified in relation to mathematics is stress and irritation.

Amanda: I don't like mathematics, but I try to do it.

Carlos: My experience with maths is a negative one. I got here but I don't know anything... I only failed in the fifth year and then here, in the first... I got here but knowing nothing. That's why it's hard! I'm trying hard!

The dislike of mathematics is linked to a perception of its difficulty. This seems to be revealed in the student's sense of a poor ability to learn it. They keep trying to overcome this obstacle but end up giving in to the conviction that they do not know and they must continue to strive. There is also a maladaptive feeling that transpires from the words of the students, who blame their lack of preparation before secondary school for the difficulties they face. Therefore, dislike, stress, and irritation are emotions related to *bad preparation*, *low ability*, and a *hard subject*.

### **Emotions associated with mathematics assessment**

Finally, the evaluation tests in mathematics emerged as the triggers of various emotional reactions, notably nervousness in performing the tests and despair for not being able to think and recall.

Amanda: Every time I'm going to take any test, I get very nervous and I end up shuffling everything (...) it's very bad because it stops us to recall what we studied; we may have even learnt but at the time of the test it seems that there is a mind blank, so... And this year it seems to be getting worse because I get very nervous, it's because of the pressure of thinking that if you cannot recover you'll 'perish'...

Ana: And the day before a recovery test, I went to the teacher's tutoring and the teacher helped me and saw that I had learned the content. She said: 'your problem is that

you get nervous when you take the test'. When I take it, I forget all those easier things like plus and minus. In the test I'm really a child.

Bruna: I had always been a good student, but as soon as I entered the IFMT, I went down like a balloon. (...) now, here, if I take a test, I'm too nervous, I forget everything, even my name...

The tests seem to have to do with objects, with agents, and with events that arouse various emotions in these students. There are events that seem to reinforce the emotion of anxiety and nervousness, as the case of the teacher who confirms this same idea with Ana, the day before a test. On the other hand, the test itself is a disruptive factor because it is seen as a time when learning is compromised and becomes ineffective. The students describe themselves as apparently powerless and bewildered, and about to lose their identity and rationality. Moreover, the students refer to a particular object, the recovery test, as a threat because it means an ultimate opportunity that they feel they must not fail. So the fear of failing gets into action once again. To conclude, the fear, the nervousness and the hopelessness are involved in experiences of *personal disability*, *high pressure*, and *high threat*.

## Final remarks

The study of failure often falls on cognitive aspects, with relatively little attention paid to the affective and socio-cultural aspects. As reported in the literature, affective aspects are usually veiled and not quantifiable, which makes it difficult to study. According to the theoretical assumptions adopted in this study, emotions are seen as reactions to different situations that students experience in their school journey. As factors inhibiting the success of these students, we can point out: i) mathematics classroom (poor teaching, bad environment, high censure, low safety, and high confusion); ii) relationship with mathematics (bad preparation, low ability, and a hard subject), and iv) mathematics assessment (personal disability, high pressure, and high threat) and those are linked to a set of negative emotions, namely: boredom, hopelessness, shame, frustration, fear, dislike, stress, irritation, nervousness. Some of those causes are stable and others unstable, and some are controllable and others are uncontrollable. Like previous studies, we acknowledge the interplay between affect and learning as a cyclical process. Moreover, our preliminary results indicate that emotions and failure are mutually reinforcing. In this sense, changes in various aspects of the classroom practices and socio-cultural norms may represent facilitating factors of success and generate more positive emotions; it is also likely that more positive emotions about mathematics itself and assessment practices can arise from breaking the logic of test-based retention. The next steps of our research will examine the link between emotions and critical events of failure and also of accomplishment, throughout a school year, by means of emotionally triggered narratives.

# Learning geometry in self-made tutorials: the impact of producing mathematical videos on emotions, motivation and achievement in mathematical learning

Daniel Barton

Bielefeld University, Germany; daniel.barton@uni-bielefeld.de

*Keywords: project, media, emotions, motivation, achievement.*

## Emotions, motivation and achievement in learning environments

Learning is a complex process, which is influenced by many parameters. “Emotions and motivation are important prerequisites, mediators, and outcomes of learning and achievement” (Schukajlow, Rakoczy & Pekrun, 2017, p. 307). Emotions, which are related to achievement activities and to success and failure outcomes, are achievement emotions (Pekrun, 2006). Accordingly emotions in school are achievement emotions, which effect students’ interest in contents or subjects and motivation to learn (Pekrun, 2006). Interest in mathematics, motivation and as a sequel of these factors a positive effect on grades and test scores can be emerged by positive activating emotions, such as enjoyment, during mathematic lessons (Murayama, Pekrun, Lichtenfeld, vom Hofe, 2013; Schukajlow & Rakoczy, 2016). It is assumed that achievement emotions are influenced by certain appraisals. In the control-value theory of achievement emotions, perceived control over and perceived value of achievement activities and outcomes are in particular relevant for the evocation of achievement emotions (Pekrun, 2006). “From an educational perspective, appraisals are important as well, since they can be assumed to mediate the impact of situational factors, and can be targeted by educational interventions intended to foster positive emotional development” (Pekrun, 2006, p. 317). To influence control, values and emotions positively Pekrun (2006) mentions important factors, like creating learning environments, which support autonomy and cooperation, giving cognitive quality instructions and inducing values, finding a performance-enhancing choice of tasks and fostering students’ self-regulation of emotions. The project, which is presented subsequent, is geared to these factors. It is assumed, that this modelling-related and applied learningconcept is based in a social and learning environment, which fosters students’ emotions, increases interest in mathematic and generates a learning effect on geometric basic competences.

## The project

In the project students of a ninth grade (N=68) of a German high school produce in groups mathematical tutorials in the field of space geometry. After an introduction of the tasks and technical equipment, each group works self-contained. The project is conducted after the students already studied the topic of space geometry, so the students have experiences in this mathematical content. In the project it is being investigated whether and to which extent a learning effect and a positive impact on emotions and motivation can be achieved by the participation. First, the students analyze a geometric body. They describe the shape, name and explain the formulas of the surface and volume and put it into an example in the real world. The focus of this working phase is on the process-related competences of mathematical arguing, modeling, using mathematical representation and elements and the mathematical communication. Furthermore the groups develop a concept for the medial

implementation of the compiled mathematical content. Afterwards the groups present their findings and concepts. Thereafter each group starts filming and implementing their mathematical results into a medial setting. Finally the groups present their self-made tutorial. It is assumed that a high degree of individual value inheres in the project. The autonomous and cooperative working, like developing a creative concept, incorporating the mathematical content into this concept and presenting their tutorials and the integration of media reinforce this assumption (Ludwig, 2008). The project-setting constitutes a learning environment like Pekrun (2006) demands.

## Research design

To determine the projects influence on stable emotions, motivation and interest in mathematics, a survey of the Project for the Analysis of Learning and Mathematics longitudinal study (Pekrun, Goetz, Jullien, Zirnbibl, vom Hofe & Blum, 2002) is used in a pre-, post- and follow-up scheme. The intrinsic motivation inventory (Deci & Ryan, 2000) is used for researching on unstable situational emotions while the project is processing. For investigating a learning effect of the project a self-developed pre-, post and follow-up test is used. The test is applied to the competence-oriented course of instruction of Nordrhein-Westfalen and comprises tasks on geometrics bodies like describing, reproducing, explaining, representation of mathematical content and appliance, working and solving complex mathematical issues. The evaluation of the findings is in progress.

# Adolescents' Endorsement of Narratives Regarding the Importance of Mathematics: A Dialogic Perspective

Naama Ben-Dor<sup>1</sup> and Einat Heyd-Metzuyanim<sup>2</sup>

Technion, Israel Institute of Technology, Israel; [naamabd@gmail.com](mailto:naamabd@gmail.com)<sup>1</sup>; [einat.metz@gmail.com](mailto:einat.metz@gmail.com)<sup>2</sup>

*Sociocultural accounts of students' identity emphasize the endorsement of narratives about learning from "significant narrators". In contrast, psychological accounts highlight adolescences as a time of separation from parents and other authority figures. In this study, we attempt to reconcile these two views based on the Bakhtinian concepts of Authoritarian discourse and Internally Persuasive discourse. The study examined the mathematical identity narratives of five adolescents, 2<sup>nd</sup> generation to former Soviet Union immigrants in Israel, participating in a STEM afterschool activity. The findings focus on three students' endorsement of one narrative, "math is important", in both individual interviews and a focus group. The analysis showed that all participants endorsed the narrative and related it to their designated identities. However, participants differed in the level of endorsement of this narrative, ranging from 'full' endorsement to 'oppositional' endorsement.*

**Keywords:** Sociocultural narratives, mathematics identity, adolescents, immigrants.

## Rationale and Goal

In recent years, students' mathematical identities have attracted increasing attention (Darragh, 2016; Radovic, Black, Williams, & Salas, 2018). Many of these studies focus on adolescence as a critical time for the development of such mathematical identities (Black et al, 2010; Heyd-Metzuyanim, 2015). Yet historically, adolescence has been treated very differently by psychological and sociocultural (or sociological) accounts of human development. Sociocultural accounts, especially those leaning on structural sociological theories which theorize individuals as products of social structure, assume that the construction of identity narratives draws on narratives authored by "significant others" (e.g. Sfard & Prusak, 2005). In contrast, psychological theories highlight adolescence as a time where individuals construct their unique identity in separation from the adults around them (e.g. Blos, 1967). This disparity, between studies that point to adolescence as a time of separation vs. studies assuming the adoption of socioculturally based narratives into one's identity, invites a closer examination of the endorsement and separation processes of students' mathematical identity. Hence, this report aims to investigate this duality of endorsement and separation in the case of three adolescents who belong to a minority community of former Soviet Union immigrants in Israel.

## Theoretical framework

The concept of identity has been notoriously ambiguous and difficult to define (Radovic et al., 2018; Sfard & Prusak, 2005). To answer this ambiguity, Sfard and Prusak (2005) suggested an operational definition of identity as "narratives about individuals that are reifying, endorsable and significant" (p. 16). They differentiated between actual (or current) identities, namely stories about the current state of affairs, and *designated identities* – stories of what is expected to be the case in the future, stating that learning resides in the gap between current and designated identities. Black and colleagues (2010) pointed to the importance of vocational aspirations and their connection to

mathematics in relation to adolescents' designated identities. Sfard and Prusak also distinguished between 1<sup>st</sup> person (1<sup>st</sup> P) identity stories (narrative told by the author about him/herself), 2<sup>nd</sup> P and 3<sup>rd</sup> P stories (narratives told by others about the protagonist, to him/her or to others respectively). They, as well as Heyd-Metzuyanim (2015), showed how 3<sup>rd</sup> P identity stories of significant narrators turn over time into 1<sup>st</sup> P identity stories.

Despite the operational clarity of Sfard and Prusak's (2005) definition, this definition is unclear regarding the status of narratives about mathematics and learning mathematics, such as "math is hard", "math is about calculations" or "math is important". Such narratives, often related to in the literature as "beliefs about mathematics", play a crucial role in shaping students' relationship with mathematics (Törner, 2014). For this matter, we incorporate into our conceptual framework Holland and her colleagues' (1998) concept of the *space of authorship*. Bakhtin (1981) suggested that a human being is always in a state of addressing different sociocultural voices and *authoring herself* and others. Holland and colleagues (1998) define this space of authorship as a "broad venue, where social languages meet, generically and accentually, semantically and indexically, freighted with the valences of power, position, and privilege" (p. 191). Drawing on these ideas, we conceptualize the *space of authoring mathematics identity* as a dynamic arena containing narratives relating to mathematics, learning mathematics and the person as a mathematics learner.

In order to reconcile the "endorsement vs. separation" conflict between psychological and sociological views of adolescence as a time of identity development, we draw on another Bakhtinian concept: the process of ideological becoming. Bakhtin (1981) conceptualized, from a discursive point of view, the process whereby individuals selectively assimilate others' words. This process begins, according to Bakhtin, with a separation between *authoritarian discourse* and *internally persuasive discourse*. Authoritarian discourse mostly belongs to parents, teachers, adults and other authoritative social figures. Bakhtin described this discourse as demanding unconditional allegiance and permitting no play with its borders, no arguing or dialogue. However, the words of others, according to Bakhtin, do not have to remain isolated and static; they can be internally persuasive and become "half-ours and half-someone else's" (p. 345). In this process the other's narratives are questioned and challenged. Morson (2004) defined these dialogically tested narratives as *internally persuasive*. Our research question in this study was thus: to what extent are adolescent students' narratives in the Space of Authoring their Mathematical Identity, internally persuasive?

## Methodology

The study included five 8th grade students (13-14 years old) that participated in a weekly STEM-oriented afterschool activity at the Technion (hereafter "the Activity"). They all studied in the same school. The study was a pilot study aiming to build conceptual and methodological tools for a future larger study on students' identity in relation to dialogic instruction in mathematics. Hence, we chose this specific population because the students were participating in a STEM activity held in our university and could be easily accessed. The students' age corresponded with the age of our future study's population. Participation in the study was voluntary, and anonymity and confidentiality were guaranteed through an informed consent letter signed by the participants and their parents. Only four cases were analyzed. The four participants were born in Israel, 2nd generation of former Soviet

Union (hereafter: 'Russian') immigrants; the fifth participant was a recent immigrant from Russia. This difference between her and the other participants became known during the data collection stage. Due to her limited ability to communicate in Hebrew, as well as our wish to maintain a cohesive framework of participants who are 2<sup>nd</sup> generation to Russian immigrants, her data was not analyzed in the study.

The study included semi-structured individual interviews with four participants that preceded one focus group interview with all five participants, all recorded and transcribed. The interviews were conducted by the first author in a separate room. Each individual interview took approximately 45 minutes and included questions intended to elicit current 1<sup>st</sup> and 3<sup>rd</sup> current identity and designated identity narratives such as "what subjects are important for you?", "what kind of student are you?", "how would your parents answer that same question?", and "what would you like to be when you grow up?". Since our focus was the dialogic aspect of the endorsement of narratives, the interviewer questioned the participants on the sources of their narratives (e.g. "who says that math is important?") and asked for justifications (e.g. "why is it important?"). The focus group lasted 90 minutes. It began with a discussion of important subjects in school and ended with discussion of participants' wishes for the future. The rationale for holding a focus group in addition to interviews was double. First, there were participants who did not want to participate in the interview but agreed to participate in the focus group. Second, we wanted to observe processes of identity construction and endorsement of narratives from students' space of authorship in a more natural, "conversational" situation, where the voices of different students could meet and be negotiated.

Data analysis consisted of a two-stage analysis. The first stage included searching the whole interview dataset for common endorsed narratives belonging to the participants' Space of Authoring Mathematics Identity as well as current and designated identity narratives and their related narratives. Here, we encountered a difficulty with relation to narratives indicating "separations", since often, narratives authored as "truths" about the world have lost their sociocultural origin. For example, "I am a student" is a narrative that rarely contains evidence of its sociocultural source, although at a certain point in time, the author must have learned from others that this narrative identifies him. For this methodological reason, we chose in our analysis to focus only on those narratives that included indications of sociocultural sources. For example, "when I was young, my father told me that art is just a hobby" is a narrative ("art is a hobby") where the identified sociocultural source is the "father". A narrative was categorized as *endorsed* if the participant voiced the narrative, at least in part, in her own voiced or agreed with the narrative voiced by others (interviewer or peers).

The second stage analysis included a close-up examination of the dialogical aspect of the narrative's endorsement. Narratives which were voiced as solely coming from an authoritative voice (for example "my parents say that...") were categorized as *Authoritative*. Signs of separation of the participant's voice from the voice of the source were derived from positioning statements that included the opinion or thoughts of the "I" in relation to the narrative. For example, "my mother thinks art is a hobby, **but I** would like to pursue it". If signs of separation were identified, we further searched for signs of *internally persuasive endorsement*. These can appear in the form of providing justifications for the narrative, such as "art is a hobby because you cannot earn money

with it". We further examined those justifications as "sub-narratives" along the same line to determine if those sub-narratives were themselves internally persuasive. Endorsed narratives, along with their justifications and sub-narratives were compared and related to students' designated identities. For reliability, we employed a consensual coding process based on both authors' mutual agreement.

## Results

For the purpose of this report, out of the four cases, we chose the three cases of Benny, Sonia and Denis, which could best exemplify the different levels of endorsement in relation to the same narrative, "math is important". The fourth participant showed a level of endorsement similar to Benny. The overall results included the examination of other endorsed narratives related to the participants' designated identities such as "art is just a hobby" and "I need these studies". The narrative, "math is important" was stated by all students during the interviews as a response to the interviewer question "which (school) subjects are important?"

### Benny's case – full endorsement

Benny participated only in the focus group, since at the time of individual interviews, he did not yet volunteer to participate in the study. In the focus group, after several students talked about the importance of different subjects, the interviewer (1<sup>st</sup> author) turned to Benny and asked: "Benny, what do you think, because I think you also said math (is important)". To this, Benny answered:

It's very important, like if you want to get accepted for the good jobs that you have regular hours and all that ... you must understand mathematics well, otherwise you get stuck in hard jobs where you break your back to get a few shekels.

Notably, these claims were authored in his own voice, as facts about the world, even though some of them (such as those relating to jobs with "good hours" in contrast to jobs "where you break your back") most probably were authored by adults around him. We base this interpretation on our acquaintance with students of Benny's age and social position who rarely have direct access to different jobs' "hours", their "regularity" and the exact physical activities that are entailed by them. Although we interpret these narratives as sourcing from the sociocultural world, the way they are authored by Benny completely hides their sociocultural origin. By that, Benny shows full separation from the sociocultural origins of this narrative; it is not related by him in any way to what his parents or other authority figures say.

In relation to his designated identity, Benny talked about his wish to become a surgeon and said he would have liked to study the subject of surgery in school and in the Activity. When asked what in the Activity was relevant to his wish to become a surgeon, he asserted: "math is always relevant" and elaborated this claim with the following justifications:

In many ways (math is important) ... measurements... say you are doing a cardiac surgery, then it is important, say, how long you have between transferring the heart, between the body from which you are taking out the heart until he gets another heart and how long it... a lot to calculate...

We see here that Benny links his designated identity as a surgeon to the narrative "math is important" and describes specific future situations as a surgeon in which he could find himself using math. Although some of the relations Benny made between the job of a surgeon and mathematics do not actually fit the place of mathematics in the surgery world, it is clear that Benny uses his conceptions of mathematics (as mostly calculations) to link to what he imagines the world of surgery to be. Since there is no mention of anyone who told Benny about this relation of surgery and mathematics, and since the connections themselves are a bit constrained and indicative of Benny's own yet limited grasp of what mathematics (and surgery) is all about, we categorize the endorsement of this narrative as internally persuasive. In no place does Benny offer conflicting narratives to the narrative "math is important" (neither in his own voice nor in revoicing someone else's voice), thus strengthening our identification of his discourse about the importance of mathematics as full endorsement.

### **Sonia's case – conflictual endorsement**

In her interview, Sonia reported liking best the subject of art and sports. Despite that, and similarly to the other participants, she claimed both in her individual interview and in the focus group, that math and English are the most important subjects studied at school, thus providing evidence of endorsement of the narrative.

When the interviewer asked her why it is so, Sonia replied:

First, (they<sup>1</sup>) say it is most important, and also, like, it's needed...it's also a very very important part of the matriculation exams...(they) always say that most important are math and English... I also think English is important.

The interviewer then asked again why math is important, and the following exchange took place:

(implied words), [overlapping speech]

- 45 Sonia: (They) say, I still don't understand why... But (they) say math is important... okay... [fine...]
- 46 Interviewer: [Who says? Who says?]
- 47 Sonia: The parents say. Like, for my mother all subjects matter, no matter which one, but like almost all people say that... English and math, I still don't understand why math. I want someone to explain it to me, why?
- 48 Interviewer Because what? Because you don't find in it anything to do with...?
- 49 Sonia Like, it's important in engineering and all that... I don't know... maybe because I don't really like the subject

### **Excerpt 1**

---

<sup>1</sup> In literal translation the word "they" would be omitted. The omitting of "they" is often used to avoid the passive voice in Hebrew.

In line 47, Sonia specifies the identity of the source to be her parents and "almost all people". There are clear signs of separation between her own voice ("I still don't understand why math" [47]) and her parents' voice ("The parents say" [47]). We thus see Sonia's endorsement of the narrative "math is important" as conflictual. Although she claimed not to have internally persuasive reasons for the narrative and even challenged the interviewer to provide her with justifications, Sonia did initially author the narrative as her own (in answering the interviewer's question which subject was most important at school), as well as provided a reason: engineering (49). The mentioning of engineering as a reason for the importance of mathematics was related to Sonia's designated identity. She said: "I already have one idea for what I want to go study... software engineer". When asked why she wants to study software engineering, she said:

...I really like computer games and I want to do software for computer games, and also actually in my opinion I think that the fact that I like drawing and with all the thoughts and fantasy, it will help me in computer games to invent something interesting.

Although in her interview Sonia mentioned the plan to be a software engineer as her own idea, two weeks later, in the focus group interview, she said, "My mother wanted me to be a software engineer. For that I need five math units<sup>2</sup>..." Despite the identification of her mother as the source of her future plans, Sonia displayed in her justifications an internally persuasive endorsement of her reason for studying mathematics (studying engineering). Thus, like Benny, Sonia links her designated identity (as a software engineer) to the endorsement of the narrative. However, she also poses conflicting narratives doubting this narrative and confirming its authoritative nature. To summarize, Sonia's endorsement of the narrative "math is important" is double-voiced and conflictual, showing signs of internally persuasive discourse together with authoritarian discourse.

### **Denis's case –oppositional endorsement**

In his individual interview Denis reported he liked computer games and sports, and that he wants to have "two degrees" and study in the "biggest university". Both in the individual interview and in the focus group interview Denis listed exact sciences (including math) as most important. When the interviewer asked why, Denis cited his mother "because she always has this thing with numbers", thus identifying his mother as the source for the narrative. In the focus group, when the subject of why math is important was raised, Denis said:

a. Because the parents force you; b. Because they came from the Soviet Union and for them math is in the blood; c. Because we are in Israel and (you) don't earn much in Israel

This claim was consistent with Denis's claim in his individual interview that 'Russian' parents try harder to teach their children math at home:

because they want the children to come out smart in the country... and Israel for them is not an easy country, not a lot of money, problems, they want their children to come out lawyers and doctors... geniuses...

---

<sup>2</sup> The matriculation exams in Israel have different level of "units". The most advanced level is "5 units".

He then added that, as their (the 'Russians') child, you need to "make as much effort as possible to impress the parents at the end of the year to show them the report card". Examining the endorsement of the narrative "math is important", it is clear that Denis separates his own voice from the identified source by positioning himself as being coerced to study hard and earn high grades because of his immigrant community. Thus, implicit in Denis words, is a narrative that in fact opposes the narrative "math is important", a narrative that could be explicated as *there are no relevant reasons for me to study mathematics aside from pleasing my parents*. The justifications to the narrative provided by Denis are all related to the source (his mother and other 'Russians') and thus cannot be categorized as internally persuasive. The links Denis makes between designated identities and the endorsement of the narrative are all related to 3<sup>rd</sup> P designated identities, that is, what others expect him to become. We thus label Denis's endorsement as oppositional.

## Discussion

This study sheds light on the process by which narratives in the Space of Authoring Mathematics Identities, originating in sociocultural voices, are endorsed and incorporated into adolescent students' 1<sup>st</sup> P identities. In addition, it highlights the connection of narratives such as "math is important" to students' designated identities. We see this in the fact that Denis, whose endorsement of the narrative was oppositional, connected the "math is important" narrative to his future ability to earn money without specifying how this narrative would be relevant to his designated identity. In contrast, Sonia and Benny (whose wishes were to become a surgeon and a software engineer) related the importance of mathematics specifically to their future desired careers. This link between narratives in the Space of Authoring Mathematics Identity and designated identities reinforces Black and colleagues' (2010) suggestion that motives, derived from students' aspiration, may play a crucial role in shaping their relationship with mathematics. In other words, although narratives about the importance of mathematics circulate around students, the answer to whether these narratives would turn from authoritative discourse to internally persuasive discourse may lie in the connection of these narratives to students' plans and aspirations for the future.

Rather than assuming a relatively straightforward adoption of narratives authored in the sociocultural sphere as some structural sociological accounts do, the present study examined the dialogic process of endorsement, based on the Bakhtinian concepts of authoritative discourse and internally persuasive discourse. Although in all three cases reported herein there were indications of sociocultural sources to the narrative "math is important", these cases showed different degrees of *separation* of the adolescents' voice from the voices of significant narrators around them. This exemplifies the process by which narratives authored by significant others are not simply "facsimiled", in the words of Holland et al. (1998) onto their children's identity. Moreover, the endorsement of the narrative by the three adolescents was different in subtle yet noticeable ways. The analysis revealed three levels of endorsement of the narrative: full endorsement, conflictual endorsement, and oppositional endorsement. Full endorsement was established by signs of an internally persuasive discourse regarding the narrative; conflictual endorsement was established by evidence of both authoritative discourse as well as internally persuasive discourse; and oppositional endorsement was established by signs of an authoritative discourse. These findings suggest that students' endorsement of narratives in the space of authorship is a complex process. The fact that a

student states for example that "math is important", and even cites his parents or author authority figures as the source of this narrative, does not provide the whole picture regarding the endorsement of the narrative and the separation of the adolescent from the authoritative discourse.

Although we present a small-scale study and our report focuses on one narrative only, our findings foreground the need to use dialogical concepts and tools when examining students' mathematical identities. Furthermore, the theoretical approach we adopted in this study goes some way in mediating between psychological approaches emphasizing adolescence as a critical time of separation from authoritative figures, and sociocultural approaches signifying the importance of narratives surrounding the students. By this, the study contributes to bridging the gap between studies taking a psychological approach to identity and studies taking a sociological, discursive take on this concept.

# Learning styles in mathematics – the strength of the motivational factors at 10<sup>th</sup> grade Portuguese students

Miguel Figueiredo<sup>1</sup> and Henrique Manuel Guimarães<sup>2</sup>

<sup>1</sup>Universidade de Lisboa, Instituto de Educação, Lisboa, Portugal; [mafigueiredo@campus.ul.pt](mailto:mafigueiredo@campus.ul.pt)

*This paper reports on a research project aimed at describing the learning styles in mathematics of the Portuguese students at the 10<sup>th</sup> grade and at relating them to the students' performance. For this quantitative, descriptive and correlational research, we used an adaptation of the ILS (Inventory of Learning Styles) of Vermunt (1994) that was answered by a sample of 579 students. An important result was the detection of a learning style that is strongly correlated to the motivational learning orientations, being however still undefined it what concerns the cognitive processing strategies. This style, if hold in a favorable context, may turn into a "meaning oriented" learning style. We also detected the four styles usually reported at Vermunt's ILS' applications: "meaning oriented", "reproduction oriented", "application oriented" and "not oriented", as well as the positive contribution of a "meaning oriented" style to the scholar performance in mathematics, opposite to the effect of the "reproduction oriented" one.*

*Keywords: Learning style, secondary school mathematics, motivation.*

## Introduction

The aim of our research was to characterize the learning styles and each of its components in relation to the learning of mathematics by 10<sup>th</sup> grade Portuguese students and to find out whether either the learning styles or any of their components show any correlation to the learning results. Such components are those considered in the Vermunt's model of the regulation of the learning processes (Vermunt & Van Rijswijk, 1988; Vermunt, 1998, 2005): cognitive processing strategies, regulation strategies, conceptions of learning and learning orientations. We opted for this model, because it follows a socio-constructivist insight of learning (Goldin, 1989) that has got in account both personal and contextual factors that influence the evolution of the individual learning styles. The reason for choosing mathematics as the discipline-object of this research lies on the personal interest of the researchers in the field of the Didactics of Mathematics, having in mind that several empirical studies reveal that the students don't use the same learning style in all the disciplines. For example, Severiens & Dam (1997) report different patterns of learning styles in four disciplines using the same sample of six secondary schools in Holland.

Following the above mentioned aim of the research, we present the questions of the study that are relevant to this paper, concerning the Portuguese 10<sup>th</sup> grade students:

- Which learning styles are more present at mathematics learning?

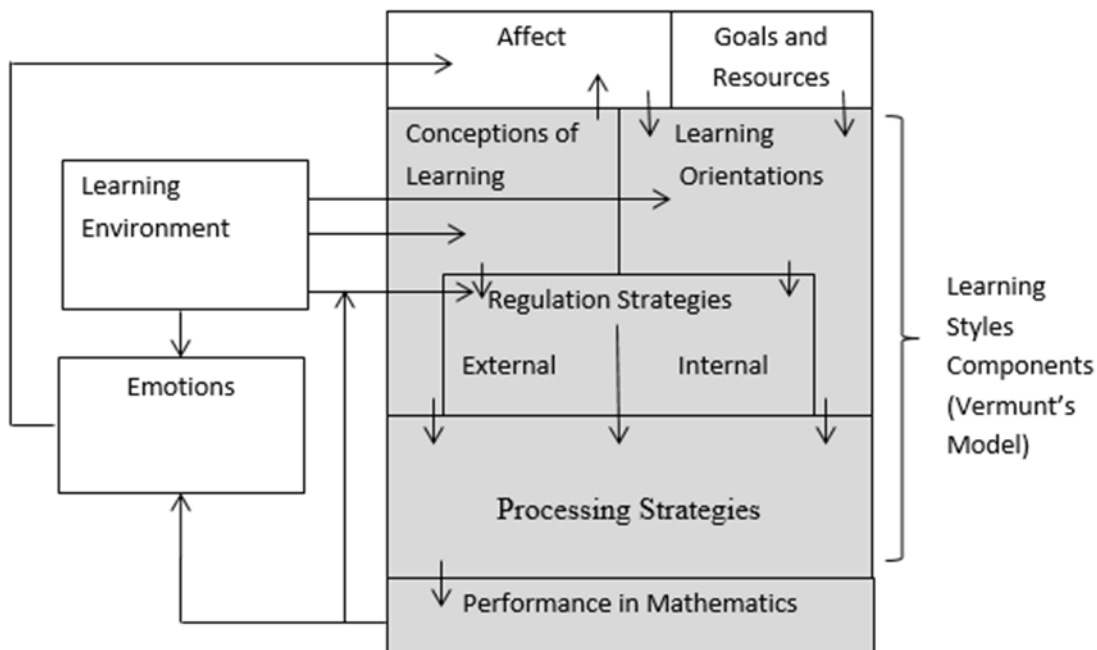

Which correlations can be found between the performance in mathematics and the learning styles?

## Theoretical Framework

One of the most used definitions of “learning style” was written by a *task-force* of NASSP (*National Association of Secondary School Principals*), created in 1979 to set the diagnostics of the learning styles of secondary school students in USA:

The learning style is the composite of characteristic cognitive, affective, and physiological factors that serve as relatively stable indicators of how a learner perceives, interacts with, and responds to the learning environment. (Keefe, 2001, p. 140)

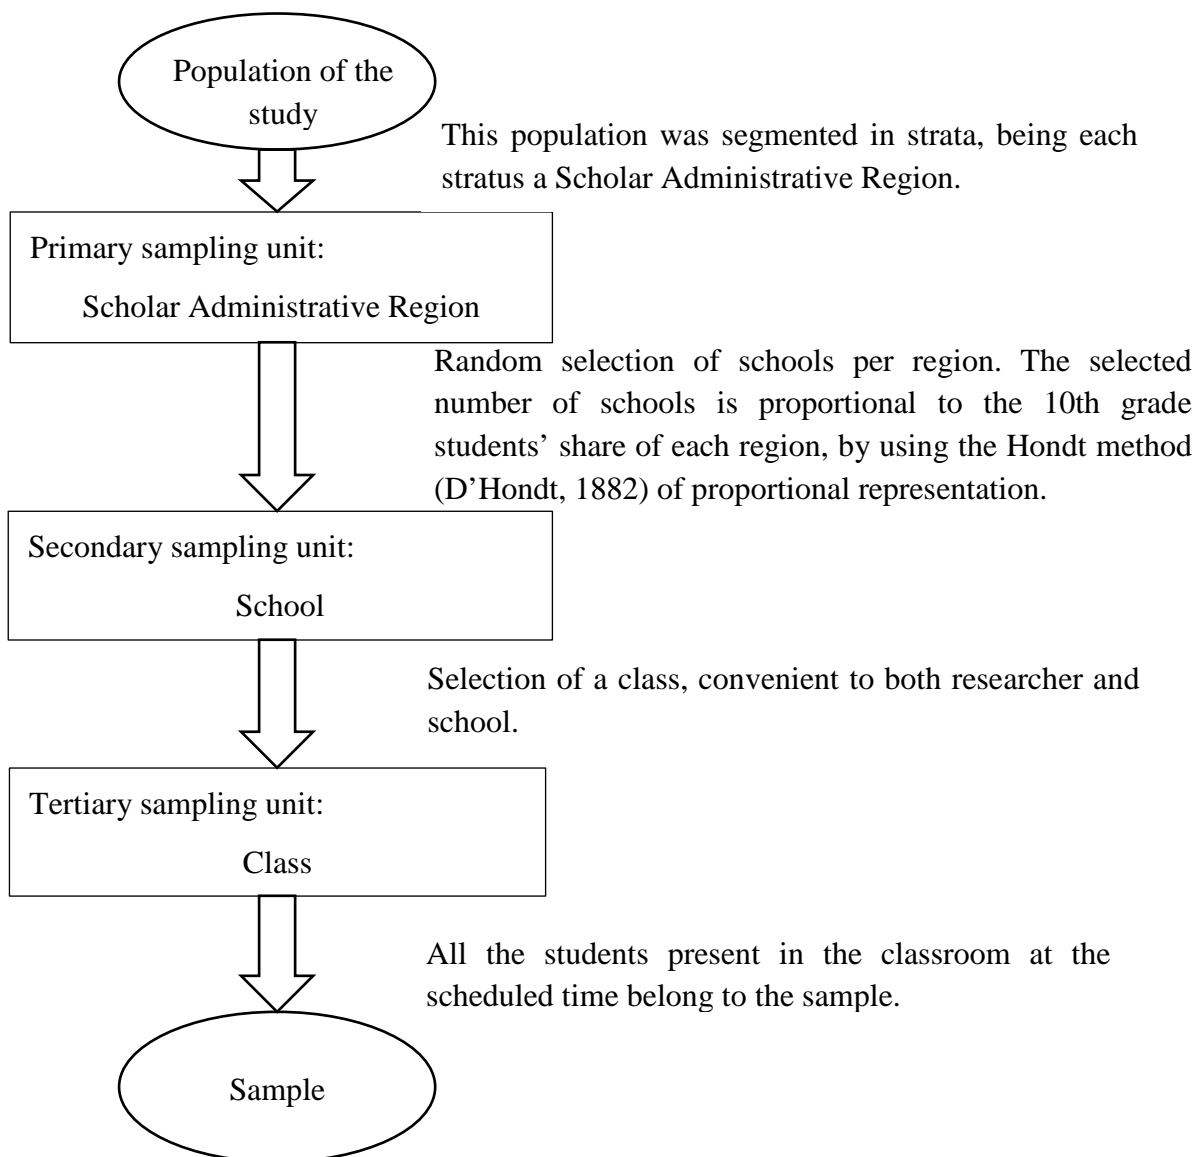

Though this study is not a longitudinal one, therefore limited by a synchronic data collecting, we conceived a conceptual framework (Figure 1) that has included some variables that, regardless the fact that they are not targeted to be measured in this research, we assume as being closely related to the four components of Vermunt’s model of the regulation of the learning processes. Therefore, the conceptual framework includes this model as a subset that interacts with other variables. For instance, the performance, as perceived by the student, feedbacks the components of the regulation model (Cassidy, 2011) and generates emotions that influence the affect for mathematics (McLeod, 1992). As a result, some changes in the motivation to learn may happen (Hannula, 2004). Besides that, the effect of the perceived performance on the self-confidence of the student may change the degree of the self-regulated learning (Malmivuori, 2006). The learning contexts, such as the school culture and the classroom dynamics, or even the social and familiar environments, are also considered at the framework. The goals of the student and the available resources also have an impact on the learning orientations (Hannula, 2006). The different mixes of attitudes and behaviors of a student within each of the learning styles components, shown in Figure 1, define the learning styles proposed by the model: reproduction oriented, meaning oriented, application oriented and not-oriented.

**Figure 1: Research conceptual framework (the measured variables are those of the grey area)**

## Research Method

For this study, we targeted the 10th grade students that were learning the discipline “Mathematics A”. The advantage of choosing the 10th grade classes was the opportunity to observe students that have just done the qualitative step of the transition from basic to secondary school and that are supposed to be able to interpret the questions written on the inventory. This quantitative, descriptive and correlational research was implemented in two steps: there was a small-scale study (n=108) that allowed us to tune up the survey tools, followed by the large-scale study (n=579). At both studies, we used a multi-stage sampling process, as shown in Figure 2.

**Figure 2: Research multi-stage sampling process scheme**

The tool that we used for the primary data collection was an adaptation of Vermunt's ILS – Inventory of Learning Styles (Vermunt, 1994). We adapted this questionnaire to a secondary school context and to the focus on the learning of mathematics. In this adaptation, we kept the structure of the Likert

scales used at the original inventory for measuring the attitudes and behaviours related to the four components of Vermunt's model (Table 1).

<b>Processing Strategies</b>	<b>Regulations Strategies</b>	<b>Learning Orientations</b>	<b>Beliefs about Learning</b>
<u>Scales:</u> Deep processing Stepwise processing Concrete processing	<u>Scales:</u> Internal regulation External regulation Lack of regulation	<u>Scales:</u> Personal Interest Certificate Self-Test Vocational Ambivalent	<u>Scales:</u> Intake of Knowledge Construction of Knowledge Use of Knowledge Stimulated Education Cooperation

**Table 1: Scales of the Inventory of Learning Styles**

The questionnaire also included three questions related to the results in Mathematics (self-assessment and school assessments in the former year and in the current year) and two questions about the demographic variables of gender and age. For the two first components, that concern the processing and the regulation strategies, the scales are behavioural. For example:

When a mathematical problem is presented at the classroom, I prefer to wait for an explanation about how to solve it, either from the teacher or from my colleagues.

Never ☐                      Sometimes ☐                      Often ☐                      Always ☐

For the other two components, concerning the learning orientations and the beliefs about learning, the scales are attitudinal. For example:

I like to learn Mathematics.

I totally disagree ☐                      I tend to disagree ☐                      I tend to agree ☐                      I totally agree ☐

The data used at the large-scale study were collected in 2016, from 15<sup>th</sup> January to 15<sup>th</sup> March, at 28 schools along the continental territory of Portugal. A researcher was always present at the classroom during the fulfilling of the questionnaire by the students, in order to assure the homogeneity of the procedures and to guarantee the anonymity of the students answers.

## Results

The results here reported are those of the large-scale study. However, it is remarkable that the findings were very similar to those of the pilot-study. This feature can be seen as a confirmation of the robustness of the adapted ILS used for the data collection. Concerning the internal validity of the scales, almost all the results of the calculations of *Cronbach's alpha* ranged from 0.6 to 0.9, showing an acceptable or even good internal validity. The single component with some scales with *Cronbach's alpha* lower than 0.6, but higher than 0.5, was the one concerning the beliefs about learning. This may have happened due to the fact that the concepts involved in the questions about those beliefs are probably not yet clear at the students mind.

The sample was quite balanced in what concerns the gender of the students: 52% female and 48% male. Most of them (78%) were 15 years old and there was a significant group (18%) aged 16 years. The minimum age was 14 and the maximum age was 18. Concerning their performances in

Mathematics, only 16% of the surveyed students assess their own performance as non-satisfactory. However, both school assessments of the 9<sup>th</sup> year and of the first trimester of the 10<sup>th</sup> year point out to 22% non-satisfactory performances.

Using factorial analysis, an adequate tool to reduce the amount of behavioural and attitudinal variables to identifiable learning styles, some common trends of attitudes and behaviours at mathematics learning could be found out. As expected, the Kaiser-Meyer-Olkin test value reached nearly 0.9 and the significance level obtained at the Bartlett test was less than 0.01, so both tests revealed that the sample was very good for this purpose. Proceeding to the factorial analysis and selecting the principal components with eigenvalues higher than 1, we could obtain five components that explain 70% of the variance within the sample. The factorial structure of these components in terms of the ILS' scales is shown by the matrix of Table 2, where we can find out the correlational saturations after the use of Varimax rotation at the analysis.

Scale	Component				
	1	2	3	4	5
Deep processing			.828		
Stepwise processing		.856			
Concrete processing				.637	
Internal regulation	.408		.775		
External regulation		.604	-.426		
Lack of regulation	-.396	.445	-.429	.355	
Personally interested	.870				
Certification oriented	-.544	.361			
Self-test oriented	.730				
Vocation oriented	.838				
Ambivalent	-.725		-.364		
Learning as intake of knowledge		.838			
Learning as construction of knowledge			.338	.625	
Learning as use of knowledge	.564			.440	
Learning as stimulated education				.738	
Learning through cooperation					.971

**Table 2: Factorial structure with 5 components**

The first component is strongly associated to the three learning orientations that result from the motivation to learn mathematics: personal interest, self-test and vocational orientations. So, it can represent a learning style that has got features that belong to the “meaning oriented” style, but it neither correlates to the deep processing strategies, nor to the belief that learning is knowledge construction. We named this style “personal fulfilment oriented” and we propose the conjecture that this style may evolve to the “meaning oriented” one, if the context of learning is favourable to this evolution. This conjecture must be submitted to longitudinal research. The second component shows features that correspond to the “reproduction oriented” style of Vermunt’s model, namely the stepwise processing, the external regulation, the certification orientated learning and the belief that

learning is an intake of knowledge. The third component sticks totally to the attitudes and behaviours associated to the “meaning oriented” learning style, such as the deep processing, the internal regulation and the belief of learning as a construction of knowledge. What is noticeable is that the motivational aspects are very strong at the “personal fulfilment oriented” style, but almost absent in the “meaning oriented” one. Our interpretation of this fact is that the first one, observable at the beginning of secondary school is more determined by the discipline-object than the latest, which is not so dependent on motivation, thus more stable. The fourth component that was extracted at the factorial analysis reveals a style similar to the “application oriented” one of Vermunt’s model, though not so clearly defined as the other styles. The main features of this style are the relevance of the concrete processing and the belief that learning is a result of educational stimulation. The fifth component is absolutely undefined in what concerns the processing and regulation strategies as well as the learning orientations, so it may be seen as a “not oriented” style. However, in this study, this style appears strongly and exclusively related to the belief in learning through cooperation. Having in mind that, as mentioned above, the correlation of this belief with the performance in mathematics tends to be negative, it is possible that the individual lack of learning strategies at this school level leads some students to look for support at group work. Observing the results that concern the linear correlation between the learning styles and the performance in mathematics assessed through three different ways (Table 3), we find that all but one are significant for  $p < 0.05$ , but not strong.

Learning Style		Self-assessment	School assessment (9th grade)	School assessment (10th grade, 1st trimester)
Personal fulfilment oriented	Pearson’s r	.453	.284	.328
	Sig. (bilateral)	.000	.000	.000
Reproduction oriented	Pearson’s r	-.233	-.256	-.346
	Sig. (bilateral)	.000	.000	.000
Meaning oriented	Pearson’s r	.281	.181	.248
	Sig. (bilateral)	.000	.000	.000
Application oriented	Pearson’s r	-.091	-.027	-.115
	Sig. (bilateral)	.029	.517	.006
Not oriented	Pearson’s r	-.152	-.144	-.148
	Sig. (bilateral)	.000	.000	.000

**Table 3: Correlation between the learning styles scores and the assessments**

It is however important to notice that the polarity of the correlations is coherent along the three different assessments. The correlations with the assessments are positive for the “personal fulfilment oriented style” and for the “meaning oriented style” and negative for all others. So, we conclude that there is a slight but observable trend of these two learning styles to generate a better performance in mathematics, whereas the other styles conduct to worse results. It’s also noticeable that the positive correlations of the styles with the assessments are more positive with the self-assessment than with the other assessments and the negative correlations are more negative with the school assessments than with the self-assessment. Our interpretation is that those students whose learning styles are predominantly “personal fulfilment oriented” or “meaning oriented” are more aware of the results of their learning processes.

## Conclusions

Starting to discuss the results by the constitutive components of the learning styles, we conclude that, in what concerns the beliefs about mathematics learning, the students at the 10<sup>th</sup> grade still didn't develop clear concepts and that the motivational dimensions are those that play the strongest differentiating role between their learning styles in mathematics. We believe that it is very important that all the contextual factors, such as the teaching methods and styles, keep this motivational predisposition in a high level, in order to give way to the evolution towards a meaning oriented style. For example, if too much stress is put on the assessment of mathematics performance, particularly when such assessment is required for any kind of certification, it may cause a drift to certification oriented learning and therefore to a learning style of a more reproductive kind, which tends to lower the performance of the student in mathematics. The four learning styles found out in many researches that used Vermunt's ILS at university or high-school students were also found in this investigation. However, another learning style, that we named "personal fulfilment oriented", is preponderant and contains features that may lead to a "meaning-oriented style", if the contextual variables help to induce the concept of constructive learning as long as the student will develop clearer concepts. These two styles of learning tend to be more suitable for better performances in Mathematics at the secondary school.

Having exposed the conclusions of our research, we must express some limitations that are inherent of our methodology. First of all, one may ask whether these results can be generalized to the population of the study. There are some factors in the sampling process that could cause interference in the randomness of the sample, namely: the convenience of the selection process of the classes, the risk of having selected classes instead of individual students, considering that some of these might be absent at the moment of the data collection, and the stratification of the population by regions in order to obtain a representative territorial distribution of the sample. If we define a random process in terms of the equiprobability of selection for each sampling unit, the assumed no correlation between the conveniences of the researcher and the schools makes this part of the sampling equivalent to a random process. Concerning the absent students, generally there were no more than one or two missing the class. Therefore, we consider that there is a high degree of generalization of the research results and that another sampling process would hardly obtain a so close approach to a random process. There are also limitations that result from the data collection process. The answers given by the students can be influenced by subjective norms, in the sense that they may consider answers in terms of the opinion of contextual agents and not of their own. Besides that, some answers may require cognitive constructs that need the use of the memory of the thoughts and emotions that have occurred at mathematics learning. The possible misinterpretation of some questions and terms might have been a limitation too. However, we believe that these limitations had little impact at the research, since the results of the pilot study and of the large scale study were very similar.

Some follow up of this research would contribute to further knowledge about the learning styles in mathematics of the secondary school students. Longitudinal studies along the secondary school cycle would help to describe the evolution of the learning styles and to test our conjecture that there is a learning-style that can turn into a meaning oriented style, if some contextual conditions are favourable

to this development. Those studies could also check to which extent the assessment methods at the end of the secondary school are influencing the learning styles adopted by the students.

# Undergraduate students' mindsets in a computer programming mathematical learning environment

Wendy Ann Forbes, Joyce Mgombelo, Sarah Gannon and Chantal Buteau

Brock University, Canada; wendyannforbes@gmail.com

*This paper focuses on how undergraduate students' mindsets are enacted and constructed in a programming and mathematics learning environment. This research draws from year one of a five-year study entitled "Educating for the 21st Century: Post-graduate Students Learning Progmatrics (Computer Programming for Mathematical Investigation, Simulation, and Real-world Modeling), which addresses the need to empower students within the STEM field. A narrative approach is employed to present findings from two students, Sydney and Jim (pseudonyms), followed by a discussion on their enacted mindsets during a first-year 'progmatics' course.*

*Keywords: Mindset. University mathematics education. Programming. Identity.*

## Introduction

Jobs in the STEM field are on the increase. A major percentage of those jobs require computer science-related knowledge (CBC News, 2015). However, students in undergraduate computer science programs often feel defeated, having little confidence in their ability because of obstacles they encounter that are inherent to programming (Cutts, Draper, O'Donnell & Saffrey, 2010; Murphy & Thomas; 2008). Moreover, many mathematics students avoid engaging in mathematical tasks that require reasoning, exhibiting phobias and anxiety in extreme cases, because they perceive these tasks as difficult (Boaler, 2016). The pressing need to educate students in STEM, combined with students' often negative responses to learning programming and mathematics, necessitate inquiry of how students perceive their intelligence and abilities as they learn these disciplines.

This paper draws from year one of a five-year study funded by the Canadian Social Sciences and Humanities Research Council (SSHRC) entitled "*Educating for the 21st Century: Post-graduate Students Learning Progmatrics (Computer Programming for Mathematical Investigation, Simulation, and Real-world Modeling)*". This study addresses the need to empower students within the STEM field and to better understand the complexities involved when students learn to appropriate tools such as 'progmatics'. The study focuses on the question of how mathematics students come to appropriate programming as a computational thinking instrument in the context of three 'progmatics'-focused undergraduate mathematics courses, called Mathematics Integrated with Computers and Applications (MICA). This course sequence teaches students the fundamentals of programming for conducting mathematical explorations and applications. Analysis of data gathered within this study provides a suitable opportunity to investigate students' mindsets as they grapple with the complexities of a 'progmatics' learning environment. Specifically, this paper will focus on how students' mindsets are enacted and constructed while learning 'progmatics' during the first MICA course. To achieve this aim, the narratives of two students, Sydney and Jim (pseudonyms), will be explored.

Mindset refers to the brain's potential to formulate perceptions, affecting attitude and achievement. Mindset was first introduced in educational research in the 1920s but in recent years, Carol Dweck's work on oppositional theories of growth and fixed mindsets has popularized mindset (Popan, 2016).

Dweck's notion of growth mindset has been applied in various contexts. Cutts et al. (2010) assert that the barrage of obstacles faced by students during their undergraduate programs promote fixed mindset beliefs. Furthermore, Murphy and Thomas (2008) contend that while self-theories are applicable in all disciplines, the way students perceive their abilities may be more significant in computer science education, particularly in computer programming, due to inherent challenges such as contending with elusive and puzzling syntax and runtime errors. Based on these arguments regarding the significance of self-theories to mathematics and programming, a growth mindset may be even more important for learning mathematics within a programming environment, given the added difficulties stemming from both disciplines. Our study adds to other mindset research focusing on mathematics or programming as it involves not only one aspect (programming or mathematics), but the combination of both disciplines.

## Conceptual Framework

Our view of learning relies on Lave and Wenger's (1991) work on communities of practice. Lave and Wenger (1991) contend that learning takes place relative to the context in which it is learned through legitimate peripheral participation, whereby *newcomers* become *oldtimers* by authentically taking part in a seamless process of gradually increasing responsibilities. The newcomer, starting at the periphery, may initially observe, but contributes within a community of practice almost immediately by doing small tasks which are progressively increased until he/she becomes an oldtimer. For Lave and Wenger (1991), the process of becoming a legitimate member of a community involves not just change in knowledgeable skill, but also a change in identity. Wenger (1998) defines this identity as "a layering of events of participation and reification by which our experience and its social interpretation inform each other" (p. 151). This definition implies that a change in mindset results from a change in identity because individuals' perceptions of their own abilities is shaped as they experience their sociocultural environment. In this sense, individual stories and narrative approach are relevant in inquiry on one's experienced mindsets. Storying or constructing narratives are common means utilized by humans to make sense of the myriad of complex experiences they encounter; contributing to the formation of their identity (McAdams, 2008), and by extension, their mindset. A narrative approach is a growing trend in research relating to identity and, in general, educational research (McAdams, 2008).

Dweck (2010) describes two mindsets, fixed or growth, that influence student performance in two distinct ways. Students with a fixed mindset perceive their abilities as stable traits, believing that they have a set capacity to be successful that cannot be changed. Students with a growth mindset, however, understand that with effort and perseverance, their abilities can be improved. Solomon (2007) asserts that a students' mathematical mindset plays a key role in developing their identity. Mindset is also a critical factor in determining a student's attitude towards learning and their level of achievement (Boaler, 2016; Dweck, 2015; Murphy & Thomas, 2008). Dweck (2010) claims that in general, individuals with a fixed mindset avoid challenges, give up easily, do not value effort, dismiss positive feedback, and are threatened by others' success. In contrast, individuals with growth mindset flourish on challenges, remain persistent despite setbacks, value effort as a path to mastery, use criticisms to improve learning, and use others' success as motivation and a source of valuable lessons. Furthermore, Murphy & Thomas (2008) note that as it relates to challenges, students with fixed

mindsets focus on performance goals by opting for easier tasks as their ultimate objective is to display their ability. In contrast, students with growth mindsets focused on learning goals and are not deterred by difficult tasks or by making mistakes, in fact, they will seek out opportunities for challenge (Dweck, 2010). Importantly, a growth mindset goes beyond effort, referring to the extent to which students use innovative strategies and seek help when they are stuck (Dweck, 2015).

## **Methodology**

Throughout the duration of the larger five-year study, a mixed-methodology approach will be utilized. An iterative design approach (Plomp & Nieveen, 2013) will be employed to refine and develop the research tools for yearly data collection and analysis. The study employs a naturalistic case study approach to examine how students' instrumental genesis of programming for mathematics develops in the MICA course sequence. This research takes place in the mathematics department of a university in Ontario, Canada. The present paper draws from data gathered in year one of the larger study, where six participants in the MICA I course were recruited voluntarily. Data gathered included each participant's four 'progmatics' projects, including both their program (called exploratory objects (EOs)) and assignment report, and semi-structured individual interviews that were conducted as a follow up to each assignment. Interview prompts were informed by a model of a student's developmental process in designing, programming and using a mathematics EO (Buteau & Muller, 2010). Data also included online post-laboratory session reflections, where after each of the ten weekly two-hour MICA lab sessions, participants recorded reflections on their learning during the lab as prompted by guiding questions. Finally, all participants completed an online questionnaire before beginning the MICA I course, followed by individual interviews where participants were asked to elaborate on their questionnaire responses. The purpose of the questionnaire and follow-up interview was to uncover baseline information about participants' background experiences in learning mathematics with technology, as well as their early sentiments towards the MICA I course.

Analysis of the study's qualitative data followed Creswell's (2008) general principles of qualitative data analysis: preparing and organizing data, exploring data, and describing and developing themes from the data. To begin the analysis, codes were developed according to categories informed by the theoretical framework (Buteau, Muller, Mgombelo & Sacristán, 2018) and related literature, with additional codes emerging during the analysis process. Each participant's qualitative data was coded individually by two researchers, who then jointly completed a thematic analysis of the data. Themes were consolidated among the six participants' analyses, leading to the development of sixteen overall themes. These themes were further regrouped into five meta-themes. In this paper, we focus on the meta-theme of identity and its subthemes of affect and students' perceptions of learning mathematics.

## **Findings and Discussion**

In this section, we present and discuss findings from two participants, Jim and Sydney (pseudonyms).. We present two narratives of the participants' individual enactment of mindsets upon entering and during the MICA I course, followed by a comparative discussion.

## Sydney's Story

With no prior programming experience, Sydney approached the MICA I course with feelings of nervousness and apprehension. In the first MICA I labs, her anxious sentiments were somewhat alleviated through interactions with her instructor, helping her to grasp basic programming concepts. She faced some challenges in the first assignment (EO1), where students were tasked with creating a program to explore a mathematical conjecture of their choosing. Sydney posed a conjecture that was a minor modification of one previously covered in the MICA I labs. She kept her program relatively simple, ensuring that she did not go “beyond [her] limits” during the coding process. The greatest obstacle she faced in completing this task was debugging her code, but with the help of a more experienced peer she created a functioning program. Sydney felt relieved that she was able to successfully complete the assignment, but was still hesitant about her programming ability and hoped that the next assignment would be easier.

Sydney experienced varying levels of success and confidence throughout the remainder of the MICA I course. The second assignment, involving the design of a program about RSA encryption, presented many challenges for Sydney. She was frustrated that she was unable to create a functioning program, compounded by the fact that she did not have enough time to seek help from a peer or an instructor before the submission deadline. Sydney felt discouraged by this assignment, claiming that she was unsure she could achieve success in the MICA program. By consulting her notes from lab and collaborating with a peer, she was able to complete the final assignments successfully and gained some confidence in her programming ability. However, Sydney ended the course hesitant about MICA II, feeling significant doubts toward her ability to learn the new programming material.

## Jim's Story

Jim began the MICA I course with a general disposition of curiosity and excitement. Though Jim had limited formal experience in programming, he had been raised by a mother employed in the computer science field and was often given the opportunity to experiment with technologies throughout his childhood. This informal understanding of programming helped Jim to feel excited at the opportunity to formally learn to code. Jim's openness towards learning programming was also reflected in his greater attitude towards learning mathematics. He believes that individuals must keep an open mind towards their mathematical abilities to avoid feeling prematurely defeated and be able to persevere through challenges.

For EO1, Jim first developed a conjecture by creatively representing prime numbers and exploring patterns amongst them. Unfortunately, Jim was unable to pursue this ambitious idea within the scope of the course and his basic programming knowledge, eventually settling for a doable yet challenging alternative conjecture, that of Pólya conjecture suggested by the course instructor. However, he expressed the desire to follow up on his conjecture, feeling confident that he could develop a program to explore it when he has greater knowledge of programming. Once his program was complete, he was pleased to see it running, but stated that he always had faith it would work. Jim encountered challenges while completing the remaining assignments and coursework but did not seem bothered by these setbacks. When Jim was limited by his beginner level knowledge of programming, he would conduct research or try to find an alternative method of solving his problems. He ended the course

understanding the advantages of working within a ‘progmatics’ learning environment, only feeling disappointed that he was not able to do more.

### **Comparison between two enactments of mindsets**

Dweck (2015) notes that mindset is a critical factor in determining students’ attitudes towards learning and their level of achievement. Analysis of both Sydney’s and Jim’s accounts of their experiences provide evidence of their mindset upon entering and throughout the course. The following quotes, taken from Sydney’s and Jim’s baseline questionnaires, provide insight into their initial sentiments and mindsets towards learning at the beginning of MICA I:

Question: This MATH 1P40 [MICA I] course has a significant component of (computer) programming. This makes me feel...

Sydney: Nervous

Jim: Very confident

Question: Because:

Sydney: I barely have any knowledge in programming

Jim: If I'm finally going to get a chance to learn this stuff, I'm all for it. I've never had problems in the past, and if anything, I was annoyed that I wasn't being taught enough.

Here, Jim describes his confidence and excitement about entering the course, explaining how he looked forward to learning the programming content. In contrast, however, Sydney highlights her nervousness resulting from her lack of programming knowledge, suggesting her initial confidence level in the MICA program was low. Notably, although Jim also had limited programming knowledge, it did not cause him to feel this same apprehension. This could indicate that he was open to challenges, possessing characteristics of a growth mindset as Dweck (2010) asserts.

There are several notable elements regarding both students’ enacted mindsets as they experienced “progmatics” over the semester, first in terms of how they approached challenges. Throughout the course, Sydney demonstrates a desire to avoid tasks that present significant challenge. For EO1, Sydney chose a conjecture that was quite similar to a conjecture covered in one of the lab sessions (see Sydney’s Story). In her EO1 follow-up interview, she explains that she did not investigate a more creative conjecture in order to avoid going “beyond [her] limits” with the coding. She also expressed that she was looking forward to EO2 due to its more specific nature, stating, “I hope it’s going to be easy”. Later in the course, Sydney noted that she enjoyed the graphing component of her EO3 because “it wasn’t that tough”.

Unlike Sydney, Jim was not afraid of taking on challenges during his time in MICA I. When asked how he selected his conjecture for his EO1, Jim explained how he tried to develop a complex conjecture by himself through creatively exploring a variety of mathematical concepts. Though his mathematical ideas could not be explored with his startup programing knowledge, and he ultimately explored a more feasible (yet challenging) conjecture as advised by his professor, he expressed interest in pursuing his ideas in the future. In his EO1 follow-up interview, Jim reflected on his initial idea, stating, “I don’t think it is as hard as everyone makes it out to be, it just requires a bit of a

different way of thinking”. Similarly, in Jim’s final assignment, he again expressed the desire to go beyond his level when developing his question and was disappointed that he did not yet have the required knowledge of programming to do more with his project.

Students’ approaches to challenges provide a strong indication of their mindset towards both learning and intelligence. The fixed mindset approach was consistently evident in Sydney’s data, as her actions and perspective routinely demonstrate how she chose to explore simpler problems and favoured assignments that were seemingly easier. In contrast, Jim routinely attempted to challenge himself when developing conjectures and mathematical questions, demonstrating a growth mindset approach.

A second notable point about Sydney’s and Jim’s enacted mindsets is how they overcame the challenges they encountered and the effects of these challenges on their attitudes towards their abilities. While Sydney was able to overcome difficulties in her first assignment with the help of a peer, her EO2 presented much more significant issues. Because of external time constraints, Sydney was unable to seek help from a peer or the course instructor, and was frustrated when trying to get her program to work. Due to her inability to create a functioning program, Sydney doubts her ability to continue in the MICA program, stating, “if [my EO2 program] goes poorly I don’t think I want to continue”. This doubt persisted until the end of the semester, despite greater success in her EO3 and EO4 tasks. When asked how she felt about taking the MICA II course next year, she responds, “I’m still hesitant... about the new things we will learn and if I can manage to understand them”.

Jim’s approach to setbacks was markedly different from Sydney’s. Throughout the course, it seemed that he used challenges to improve his strategies for future assignments instead of allowing them to diminish his confidence. Though he experienced setbacks in his EO2, Jim reflected on this process and how those challenges helped him improve. When he was asked in his EO3 follow-up interview if he would do anything differently, he expressed the following:

Jim: I feel like in assignment two... halfway through I had stopped planning and kind of regretted that afterwards, as you kind of get lost in the code but... for this [EO3] project I planned fairly well, I didn’t get lost... I’m pretty happy with the way I did it.

In EO3, Jim had to do a fair amount of debugging to get his program to work, but he did not seem frustrated and used clear strategies to get his program to work. When asked about the obstacles he faced in EO3, Jim stated, “with computer programming, you accept that you are going to run into some bugs, which is why you test it at different stages”. Jim maintained this attitude when completing his final assignment. When asked about debugging his program in the EO4 follow-up interview, he responded, “It didn’t work for a bit. I went back and looked at it and realized that I had forgotten something, but nothing really significant”. At the end of the course, Jim did not face the same doubts as Sydney towards his ability to be successful in MICA II. When asked about moving forward, he claimed, “I think it would be a reasonable course to take next year”.

This approach to assignments and challenges is linked to two broader themes of mindset noted by research in a variety of contexts (Boaler, 2016; Murphy & Thomas, 2008; Cutts et al., 2010), underscoring much of Dweck’s work. These contrasting mindset themes are labelled as the helpless pattern and the mastery-oriented pattern. Students that view intelligence as fixed are more likely to demonstrate a helpless response to significant challenges; whereas students with a growth mindset

display a mastery-oriented response to setbacks. Students who exhibit the helpless pattern are easily defeated when faced with challenges, measuring their capability against the obstacles and significantly doubting their ability to succeed when faced with a difficult task. Conversely, students who display mastery-oriented responses remain motivated through setbacks, persevering through the problem and overcoming it by applying innovative strategies (Diener & Dweck, 1978). Sydney's and Jim's responses to the challenges they face could give further insight into how these patterns are enacted within a 'progmatics' learning environment. Sydney's response to challenges shows aspects of the helpless orientation stemming from her fixed mindset, as she is quickly overcome with doubt and discouraged by setbacks. In contrast, Jim was not deterred by mistakes and setbacks, which he perceived as a natural part of programming. Jim's ability to persevere and flourish when faced with obstacles illustrates a mastery-oriented response in accordance with his growth mindset.

## Conclusion

This paper highlighted the enactment of two students' mindsets in the context of an introductory 'progmatics'-focused undergraduate course. Because of the inherent challenges in learning programming and necessity of resilience in the field of mathematics, having a growth mindset holds particular importance in a computer programming mathematical learning environment such as MICA I. The assignments and reflections of two MICA I students, Sydney and Jim, were compared to illustrate their differing mindsets towards their intelligence as they engage with 'progmatics' through legitimate peripheral participation (Lave & Wenger, 1991). As a result of their differing mindsets, Sydney finished the course feeling doubtful towards her ability to be successful in MICA II, while Jim maintained his confidence and expressed the desire to further develop his programs. Considering the important role played by programming and mathematics in STEM jobs, it is critical that students are encouraged to pursue and achieve success in these fields. Our work provides a beginning of how we can explore students' mindsets as they learn using programming for mathematics investigations and applications.

# Situation Specific-Skills Working Backward Reasoning: The Student's Perceptions and Affect Dimension

Inés M. Gómez-Chacón<sup>1</sup>, Marta Barbero<sup>1,2</sup>

<sup>1</sup>Universidad Complutense de Madrid, [igomezchacon@mat.ucm.es](mailto:igomezchacon@mat.ucm.es), <sup>2</sup>Università di Torino

*This study focuses on the perceptions of mathematical students on the use of backward reasoning. Since an integrative model of interactions between emotions and thinking is showed new understanding of cognitive phenomena of backward reasoning. Based on a questionnaire to assess the mathematical cognitive processes, difficulties of backward reasoning and emotions among mathematical undergraduate students, the rule structure obtained from the use of the CRT (Classification and Regression Tree) methodology analysis is reported.*

*Keywords: Backward reasoning, Heuristics, Cognition and affect, Mathematics, Perception, Regression trees*

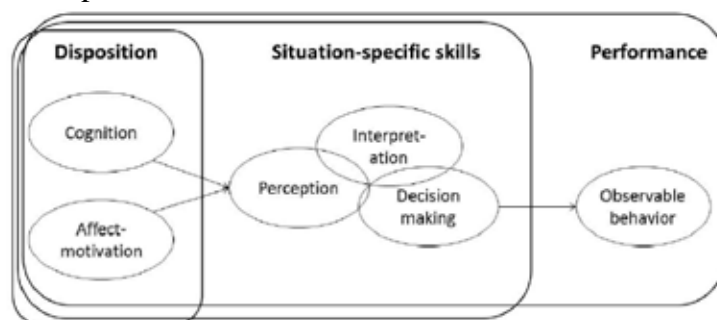

## Introduction

The purpose of this study was to determine the perceptions of mathematical students on the use of backward reasoning and how this perception may mediate between the disposition and performance of mathematical and cognitive processes involved in this type of reasoning. Backward reasoning has great potential in the study of mathematics - it can be used to improve student achievement and to help develop mathematical argumentation and proof processes. Among the challenges in university teaching we focus on mathematical thinking, where learning the method of analysis is a critical issue (Antonini, 2011, Peckhaus, 2002, Wickelgren, 1974, Xu, Xing & Van Der Schaar, 2016). Wickelgren (1974) analyses and systematizes the methods of problem solving, introducing contradiction and working backwards as two strategies that require operations to be performed on the expected result, as well as on the information given. Addressing mathematics and engineering students, he examines how the explicit teaching of theoretical and practical analyses of problems can overcome the difficulties experienced by the students. This author indicates it is more difficult to work backwards than to work forwards, so it is necessary to offer students a large class of problems to which the method of working backwards is appropriate, such as games of the Nim family of games presented here. In our previous research papers at university level (Gómez-Chacón, 2017; Barbero & Gómez-Chacón, 2018), it was identified that explicit teaching of theoretical aspects is not enough, that there might be factors in the cognitive and affect interplay, which would inevitably cause difficulties for students to construct and work backwards. These studies showed emotions continually exert numerous so-called operator effects, both linear and nonlinear, on attentional activity and on the ability to perceive relative to goal-path obstacles and overcoming them. Understanding is linked with the appraisal of their ability to influence (control dimension), with their ability to predict, and with mental flexibility.

Hence, a conscious integration of backward reasoning when learning mathematics at university, raises the need for an articulation between dispositional and cognitive aspects. In this study we try to contribute to a more comprehensive understanding of the origins of the difficulties and identify conceptual and methodological challenges involved in assessing competencies about backward reasoning in higher education, using strategy games as specific tasks.

When integrating a cognitive and a situated perspective, Blömeke et al. (2015) suggested considering competence as a continuum (cf. Fig. 1), they stated that “processes such as the perception and interpretation of a specific situation, together with decision-making may mediate between disposition and performance” (p. 7). This framework considers competence as a multidimensional construct, and resolves the dichotomy of “disposition versus performance” as

follows: “[...] our notion of competence includes ‘criterion behaviour’ as well as the knowledge, cognitive skills and affective-motivational dispositions that underlie that behaviour” (Blömeke et al. 2015, p. 3). Following this understanding, a key role is assigned to situation-specific skills, as in-between processes that explain how dispositions are translated into classroom performance. The aim of this article is to focus on perception, as the way in which something is regarded, understood, or interpreted, as a situation-specific skill that is linked to students knowledge about backward reasoning and its practice. A set of variables measuring difficulties and appraisal cognition helps us to identify these relationships.

**Fig. 1 Competence modelled as a continuum (Blömeke et al. 2015a, p. 5)**

A specific methodological challenge in the context of the affect-cognition interplay is to explain the gradualness of the processing of affective mechanisms. This paper explores the use of decision trees to analyse data from questionnaires, which focus on the use of backward reasoning. Thus, here we will report our results in the form of a tree structure, providing rules to assess the state on the use of backward reasoning (perception, difficulties and mathematical and cognitive processes) in mathematical undergraduate students.

## Characteristics of backward reasoning

The typical mathematical thinking process that is used in the discovery phases, is the backward reasoning. Pappus was the mathematician who has contributed substantially to the clarification and exemplification of the method. In the seventh book of his *Collectio* (~340 AD) he deals with the topic of Heuristics (methods to solve the problems). He exemplifies the method of analysis and the method of synthesis, therefore making the development of this reasoning clearer. Pappus defines the method of analysis as follows: “In analysis, we start from what is required, we take it for granted; and we draw correspondences (ακολουθον) from it, and correspondences from the correspondences, until we reach a point that we can use as a starting point in synthesis. That is to say, in analysis we assume what is sought as already found (what we have to prove as true).” (elaboration by Polya, 1965 by Hintikka and Remes, 1974).

The concept of Backward Reasoning involves some characteristics that allow us to identify its development throughout the resolution of a task. Different philosophers and mathematicians from the ancient Greeks, through the authors of the 17th and 18th centuries to the year 2000 have studied its characteristics. The main features are the following:

- *Direction vs cause-effect.* In Pappus’ definition, the backward direction of reasoning is highlighted. This entails going from the end of the problem to its beginning. By applying the method, the premises of a certain idea are sought. In the 17th and 18th centuries, authors such as Arnauld and Nicole interpreted the method as a search for cause-effect relationships between ideas. By these, the connection between the notions in background and the problem are identified. The knowledge of the development of the resolution of the task and the effects and causes of each notion involved in the process arise (Beaney, 2018; Peckhaus, 2002).

- *Decomposition*. According to Plato and Pappus, this kind of reasoning allows for the reduction of the problem to its simplest components. The properties that define the relationships between the most complex and the simplest objects involved in it are identified by extracting and investigating the principles that are at the base of the task. Aristotles, for example, underlines the fact that "sometimes, to solve a geometrical problem, you can only analyse a figure", breaking it down into its basic components and understanding the different parts of it (Beaney, 2018).

- *Auxiliary elements*. Kant, Polya and Hintikka, focus their attention on a fundamental part of the process: the introduction of new elements. In the progressive and deductive processes all the bases are given and from these, consequences are elaborated. Unlike the backward reasoning, new notions appear and develop throughout the resolution at specific moments, according to the needs of the solver (Beaney, 2018; Hintikka & Remes, 1974).

- *Strategies*. Backward reasoning involves different problem-solving techniques: backtracking heuristic, method of Diaeresis, Reduction ad Absurdum (Beaney, 2018).

We will focus on the *backtracking heuristic*. This is the strategy of working backwards, it consists rather of doing some steps backwards in the process. These steps can be done starting from, the end of the problem, or during the process of resolution in combination with progressive steps.

## Research questions and methodology

### Research Questions

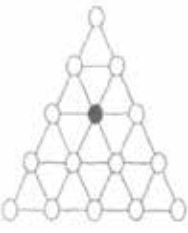

We particularly pursued the following research questions: RQ 1: What are students' perception of the use of the *backtracking heuristic*? RQ 2: What difficulties are more prevalent in the development of the *backtracking heuristic*? RQ 3: What are the affective, mathematical and cognitive processes that have impact on the development of the *backtracking heuristic*?

### Participants and instrument

Data was collected from 32 (19 women and 13 men, aged between 21 and 23) Caucasian undergraduates working toward a BSc. in mathematics. All of the participants were in their last year of academic study. They were following advanced courses in several areas of geometry, algebra, probability and analysis. With regard to solving problems, the students had been introduced to the problem solving heuristics and they received training as students in one subject related to advanced professional knowledge, practice and relationship skills relevant to teaching. They had not received any special training about backtracking heuristics.

The work dynamic started with individuals being given paper and pencil, with which they needed to resolve two games, each lasting one and a half hours. Fig. 2 shows the problem which we will analyse in the results section. Strategy games allow for the natural development of regressive reasoning. These games are disconnected from the mathematical content which forces the student to use their mathematical knowledge acquired in their university degree.

*The Triangular Solitaire* is a game for a single person that requires a board with 15 boxes, as the figure 2 shows.

	<p><i>These are the rules:</i></p> <ol style="list-style-type: none"> <li><i>1. Place the pawns in all boxes, except in the one marked in black.</i></li> <li><i>2. The player can move as many pawns as are the chances of jumping a pawn, adjacent to an empty box (along the line); at the same time, he "eats" and retreats from the table the pawn that was jumped. All pawns will move in this way. Pawns can move around the table.</i></li> </ol> <p><i>Target: The player wins when there is only one pawn on the table.</i></p>
-----------------------------------------------------------------------------------	-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

**Fig. 2. The Triangular Solitaire**

Students were given the game and asked to describe their approaches to solving the problem on protocols including: thought processes in the resolution, explanations of the difficulties they might face, and strategies they would use in order to solve with paper and pencil. Afterwards, each game was followed by a questionnaire focused on heuristics related to backward thinking and the difficulties that are generated during the process of solving problems, emotions and cognitive processes (Gómez-Chacón, 2017). The cognitive dimension refers to the characterization of the personal meanings of the subjects on the cognitive dimension of backtracking heuristic, or backward reasoning, and the cognitive appraisal processes of the interaction feeling puzzled.

1. Indicates how often you use the working backwards strategy when you are solving the problem

Now focus on the solving process of *Triangular Solitaire*

- 2- Have you used backward reasoning or backward strategy to solve the problem? Yes/No. Why?

3- If you did not use the strategy, what type of processes did you consider to have failed to take account of in the *backtracking heuristic* in your solutions. You have to choose between the following items (You can justify your statements with "extracts of the problem".):

1. Actions involved basically in the determining of the mathematical model
2. Attainment of sufficient conditions
3. Actions of discovery
4. Recognition and explanation of the meaning of representational equivalence
5. Creation of the object solution
6. Formulation of axioms
7. Characterisation and establishment of relations
8. Attainment of justifications of adequate conditions in propositional equivalences.

7. When you tried backward strategy, how well could you predict what was going to happen in this situation? (Ability to predict).

8. When you wanted to use backward strategy, how much did you feel there were problems that had to be solved before you could get what you wanted? (Goal-path obstacle).

9. When you were feeling puzzled, how much of an ability did you feel you had to switch between modes of thought and to simultaneously think about multiple concepts? (Mental flexibility).

10. Indicate the degree to which the following emotions were felt whilst solving the problem: confidence, pleasure, confusion, surprise.

**Fig. 3 Examples of some items from the questionnaire**

In Fig. 3 shows examples of some items from the questionnaire. Items 1, 2, 3 are focused on the perception of difficulties, (the difficulty in the creation of the solution, the actions of discovery, the characterisation and establishing of relationships, and the basic actions involved in determining the mathematical model can generate) while items 7, 8, 9 are referred to the processes of evaluation (cognitive appraisal) and item 10 about emotions. The cognitive dimensions of assessment were as follows: pleasantness, attention activity, control, certainty, goal-path obstacle, anticipated effort, and mental flexibility. Furthermore, emotions such as confidence, pleasure, confusion, surprise were assessed (Gómez-Chacón, 2017).

## Data analysis

Both qualitative and quantitative methods were used to address the subject of this study. This paper presents the quantitative analysis performed on the undergraduate students' written responses to the questionnaire. The CRT (*Classification and Regression Tree*) methodology is a data mining approach widely employed to develop 'IF-THEN' rule models in order to explain the behaviour of a variable of interest (the dependent variable) in terms of logical conditions over a set of explanatory or independent variables (see Breiman et al., 1984). Particularly, the CRT methodology allows for the determination of a subset of the available independent variables as well as a set of conditions over these variable's values that separate the data into groups as homogeneous as possible in terms of the values of the response or dependent variable. Regarding this aim, the CRT method performs successive dichotomous splits of the data by identifying both the independent variable and its cut-point that provide the greatest variability (i.e. variance) reduction at the split data groups verifying either condition (i.e. being greater or lower than such cut-point).

In this work we apply this regression tree methodology to develop a rule model capturing the relationships between a numerical dependent variable, measuring either the intensity of perception of using backward reasoning experienced by students while solving a mathematical problem, or a set of independent variables measuring the difficulties and mathematical and appraisal cognition. Different regression trees analysis were performed with SPSS to uncover the prescriptive nature of the variables. Two regression trees, together with their associated rule models, are reported next.

## Results

### Students' perception of the use of backtracking heuristics

In the comparison between the analysis of the protocols and the questionnaires, a discrepancy emerged between the real use of the backward strategy and the perception of its use by the students. 14 students (43.75%) were aware of using the strategy, 9 students (28.13%) were aware of not using the strategy, 4 students (12.5%) planned to use it, but it does not appear in the protocols and 5 students (15.63%) were not aware of having used it. This led us to track the students' perceptions in depth.

### Difficulties of mathematical cognition in backtracking heuristics

Table 1 shows the percentages of students (in the questionnaire) who, according to the cognitive aspects of reasoning have failed to consider the *backtracking heuristic* use in their solutions.

To analyse the relationships between the difficulties expressed by the students and their perception of the use of backtracking heuristics (BH), we will use the classification tree of Figure 4 (Classification and Regression Tree (CRT) analysis). For the interpretation of the classification tree, we should go looking at the nodes and branching them until the final leaves. First, we look at the root node 0 that describes the dependent variable: Perception of the use BH to solve the problem (Q1). It indicates that 56, 2% has this perception. Then, note that the data is split into nodes 1 and 2 depending on the variable "*I consider that my process lacked the characterisation and*

*establishment of relations*” (Q3\_7), indicating that this is the main predictor variable. The node 1 indicates that 75% of the students do not consider that the process *lacked the characterisation and establishment of relations*”. The 70,8% of these students have perception of the use of backtracking heuristics (BH)

Actions involved basically in the determining of the mathematical model	31%
Formulation of axioms	25%
Actions of discovery	22%
Characterisation and establishment of relations	22%
Attainment of sufficient conditions	19%
Creation of the object solution	16%
Attainment of justifications of adequate conditions in propositional equivalences.	16%
Recognition and explanation of the meaning of representational	13%

**Table 1. Mathematical cognition processes in backtracking heuristics**

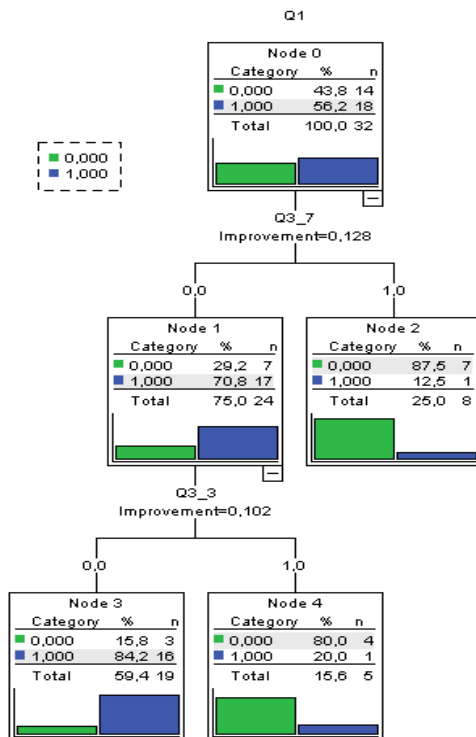

This node 1 is again split up into nodes 3 and 4 depending on variable Q3\_3 (*I consider that in my process there lacked the actions of discovery*”). We note in node 4 formed by the students that have difficulties in *the actions of discovery* (15,6% of the group) only have the perception of the use BH to solve the problem the 20%, , while students at node 3 that do not have this difficulty (59,4% of the group) have the perception of the use BH to solve the problem a 84,2%. These two nodes 3 and 4 are leaves that allow us to infer rules 2 and 3 below. Particularly, each path from the root of a decision tree to one of its leaves can be transformed into a rule simply by conjoining the conditions along the path to form the antecedent part, and taking the leaf’s mean as the rule prediction or consequent. Similarly, in order to define the rest of the rules, node 2 and the following ones are studied. The inferred rules are the following:

Rule 1 (node 2): IF *there are difficulties in the characterisation and establishment of relations* (Q3\_7) THEN the prediction of the use of BH is supported by 12,5% of students.

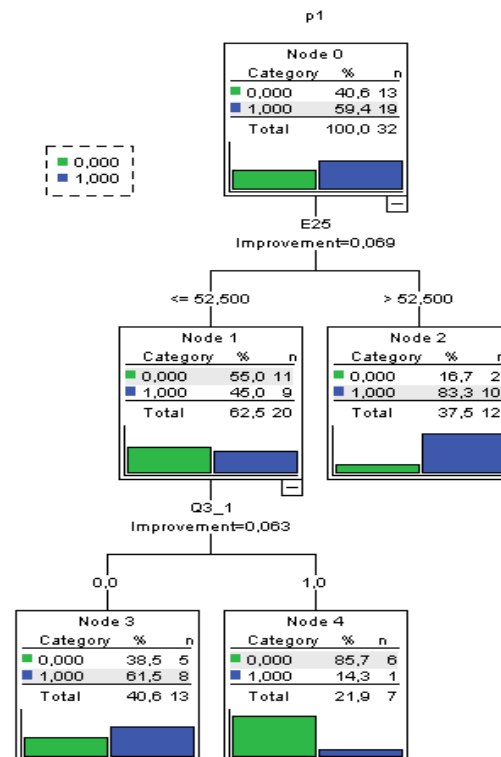

Rule 2 (node 3): IF *there are not difficulties in the characterisation and establishment of relations* (Q3\_7) AND *there are not difficulties in the actions of discovery* (Q3\_3) THEN the prediction of the use of BH is the 84,2% of students.

Rule 3 (node 4): IF *there are not difficulties in the characterisation and establishment of relations* (Q3\_7) AND *there are difficulties in the actions of discovery* (Q3\_3) THEN the prediction of the use of BH is the 20% of students.

As we described in section 2, *characterizations of backward reasoning*, there are some fundamental elements that characterise the development of this type of reasoning on which relationships are identified with the affective and cognitive aspects. These processes necessarily involve different cognitive processes and specific skills in the subject such as, mental flexibility, control or ability to identify the problems that need to be solved beforehand as well as feelings of confidence and pleasure.

**Fig. 4: Difficulties on mathematical cognition in backtracking heuristics according to the student's perception**

**Fig. 5: Cognitive appraisal dimensions affecting the real use of backtracking heuristics**

### Affective and cognitive appraisal dimensions influencing the real use of backtracking heuristics

In the process of solving the problem, results indicate that only a 47 % of students show confidence working backtracking heuristics, and a degree of pleasure of mean: 36.86, indicating that *actions involved basically in the determining of the mathematical model* is the main predictor variable. The pleasure is greater (mean: 47.81) for those who use models.

From the classification tree ((CRT) analysis), the exploration of the real use of backtracking heuristics and some of the cognitive appraisal dimensions (Fig.5), we can infer the following rules:

Rule 1 (node 2): IF (*Mental flexibility* (E25)(>52.50) the prediction of the use of BH is the 83,3%.

Rule 2 (node 3): IF ((*Mental flexibility* (E25)≤ 52.50)) AND (“*There are not difficulties in the actions involved basically in the determining of the mathematical model*” (Q3\_1)) THEN the prediction of the use of BH is the 61.5% of students.

Rule 2 (node 4): IF ((*Mental flexibility* (E25)≤ 52.50)) AND (“*There are difficulties in the actions involved basically in the determining of the mathematical model*” (Q3\_1)) THEN the prediction of the use of BH is the 14,3% of students.

### Conclusions and discussion

The data shows that knowledge and use of backward reasoning are linked to situation-specific skills, namely, perception and planning of action through cognitive process. From the regression

trees analysis of the data, the following hierarchy of themes emerged as components of students' perceptions of the use of BH: associations between difficulties in the characterisation and establishment of mathematical relations and difficulties in the actions of discovery; and in the real use of BH: the person's ability of mental flexibility and the actions involved basically in the determining of the mathematical model. The perception of the use of BH is related to the difficulties while the real use of it is related to personal cognitive skills and specific concrete actions that entail the BH. The emotions, such as confidence and pleasure, arose out of information-oriented appraisals and the use of models or *actions involved basically in the determining of the mathematical model*.

These variables can significantly predict students' performance in backward reasoning in terms of: (a) identifying that backtracking heuristics are important in a problem solving situation; (b) using some characteristics of backward reasoning (mathematical processes, skills and the person's ability); and (c) making connections between broader features of backward reasoning to overcome specific difficulties.

# Teacher-student eye contacts during whole-class instructions and small-group scaffolding:

## A case study with multiple mobile gaze trackers

Eeva Haataja, Visajaani Salonen, Anu Laine, Miika Toivanen and Markku S. Hannula

University of Helsinki, Finland, [eeva.haataja@helsinki.fi](mailto:eeva.haataja@helsinki.fi), [visajaani.salonen@helsinki.fi](mailto:visajaani.salonen@helsinki.fi),  
[anu.laine@helsinki.fi](mailto:anu.laine@helsinki.fi), [miika.toivanen@helsinki.fi](mailto:miika.toivanen@helsinki.fi), [markku.hannula@helsinki.fi](mailto:markku.hannula@helsinki.fi)

*Recent gaze tracking research have illustrated patterns of teachers' visual attention in the classroom. However, the reciprocity of teacher-student interaction needs to be explored using multiple mobile gaze tracking. This descriptive case study is our first step to chart the role of dyadic eye contacts in the teacher-student interaction during collaborative mathematical problem solving. Our results indicate that, during mathematical problem solving, teacher gaze at student faces and student gaze at teacher face vary between whole-class instruction and small-group scaffolding moments. As a conclusion, we suggest that forming dyadic eye contact requires optimal interactional, personal, and environmental states, and this method can offer us fruitful information on the micro-level processes of teacher-student interaction.*

*Keywords: classroom orchestration, multiple gaze tracking, mathematical problem solving, teacher-student interaction*

### Introduction

The teachers' complex task of orchestrating the classes and lessons consists of interaction on various social levels (Prieto, Sharma, Kidzinski, & Dillenbourg, 2017). In the classroom, a great deal of teacher's visual attention focuses on her students (McIntyre, Mainhard, & Klassen, 2017). The teacher's visual attention is affected by the social interaction in the classroom (Prieto, Sharma, Kidzinski & Dillenbourg, 2017).

Recent research have illustrated the patterns and characteristics of teachers' visual attention during instructing the students (cf. Haataja et al., 2018a; McIntyre, Jarodzka, & Klasse, 2017; Prieto et al., 2017). This study brings new dimensions to this discussion by using multiple gaze tracking between the teacher and the students in the context of collaborative problem solving. We claim that connecting teacher's gaze at student face and student's gaze at teacher face in authentic classroom contexts reveals us unexplored micro-level information on teacher-student interaction.

### Classroom interaction as whole-class instruction and small-group scaffolding

Teacher actions of classroom orchestration vary from whole-class instructing to guiding an individual student (Prieto et al., 2017). In whole-class interaction, the teacher's visual attention distributes unevenly between the students (Dessus, Cosnefroy & Luengo, 2016). Gaze tracking research has shown that instructing the class as a whole and paying attention at students' faces increase the cognitive load of a teacher. Cognitive load decreases when the teacher focuses on single student's solutions or his own notes (Prieto et al., 2017). Cognitive load increases person's perseverance and experiences of positive emotions during the task (Maranges, Schmeichel, & Baumeister, 2017).

In this study, we investigate two forms of teacher-student interaction during collaborative problem solving: whole-class instructing and small-group scaffolding. Scaffolding refers to the teacher's actions in a student group during a problem-solving learning process (Wood, Bruner, & Gail, 1976). The content and the direction of scaffolding influence the learning and the social interaction of the group. The teachers offer scaffolding on both mathematical contents and procedures and on peer interaction (Akkus & Hand, 2011; Ding, Li, Piccolo & Kulm, 2007). Our previous analysis on the data of this study showed that the teacher's intention in scaffolding interaction directs her visual attention mostly between mathematical solutions, student faces and hands (Haataja et al., 2018a; Haataja, Garcia Moreno-Esteva, Toivanen, & Hannula, 2018b). The teacher's role in supporting beneficial collaboration and successful discourse within the class is crucial (Cross, 2009).

### **Eye contact in teacher-student interaction**

In social interaction, eye contact conveys warmth and communion on one hand, and agency and status on the other (Mehrabian, 1972). The occurrence of eye contact is found to be dependent of various variables. Other person's friendly response to eye contact initiative increases the experienced liking of her (Frischen et al., 2007). Teacher's eye contact, together with her open body position, use of personal examples, and humor form warmth that encourages students into participation and interaction (Roberts & Friedman, 2013). Teacher's gaze towards students, while asking questions and listening to them, increases their experience of close interpersonal relationship with the teacher (McIntyre et al., 2017).

The teacher can also address her authority in the classroom with direct gaze at student face (Mehrabian, 1972). With eye contact, the teacher can communicate that the students are in the locus of her attention and instructions (Adams, Nelson, & Purring, 2013; McIntyre et al., 2017). Additionally, an eye contact can convey the teacher's emotional state to students (Zeki, 2009).

The shorter the distance between the teacher and student is, the higher is the quality and amount of visual interaction between them. Beyond five metres, the visual interaction decreases significantly, as the distance to the source of information distracts the attention (Cardellino, Araneda & García Alvarado, 2017).

### **Research questions**

The aim of this case study was to explore the general tendencies of teacher-student eye contacts during mathematical problem solving. Thus, our research question were:

1. How do one-way face-targeted gazes and dyadic eye contacts between teachers and students distribute during collaborative problem-solving phase of a mathematics lesson?
2. Does this distribution differ between whole-class instruction and scaffolding interactions?

### **Methods**

The participants of this study were two Finnish mathematics teachers and their 9<sup>th</sup> grade classes. Both classes included 19 students. The first teacher, called by pseudonym Joanne, was 39 years old and had 14 years of teaching experience at the time of the data collection. In Joanne's class, the target group students were four girls. The second teacher, Fred, was 30 years old with three years of teaching

experience. In his class, the target group consisted of four boys. Both teachers and their students had volunteered for participating in this research. Written consent for data collection was inquired from the school principals, all the students in the classes, and the teachers.

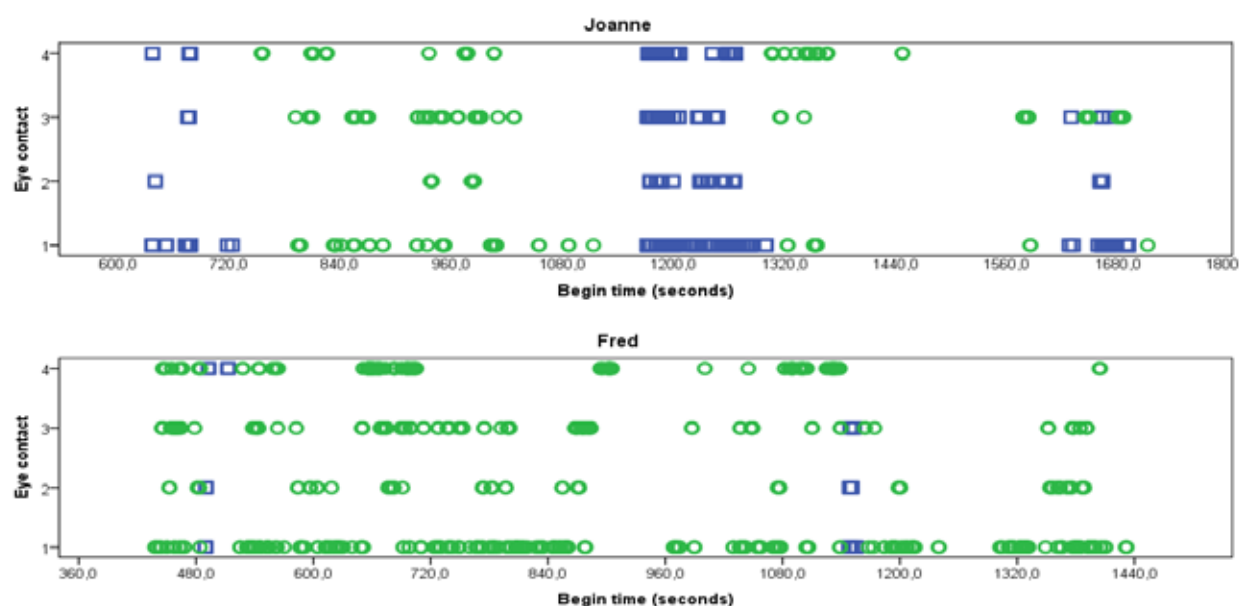

We collected the data in both schools in May 2017. To record the interaction in the classrooms, we used three video cameras and several microphones. The teachers' and target students' visual attention was recorded using self-made mobile gaze tracking devices consisting of eye cameras, a scene camera and goggles (for further information, see Toivanen, Lukander, & Puolamäki, 2017). The laptops, that recorded the gaze-tracking data, were located in backpacks to enable moving around the classroom for the participants. After the lessons, we conducted stimulated recall interviews with the teachers and target students. Unfortunately, one student gaze data and Joanne's interview were missing due to technical problems.

During the data collection lessons, the students worked on a geometrical problem task. The goal of the problem solving process was to find the shortest way to connect vertices of a square. For this report, we have analyzed the collaborative phases of the lessons. During these phases (16 minutes in Joanne's and 18 minutes in Fred's class), the students worked on the problem task collaboratively. They were encouraged to discuss their ideas and solutions in small groups. In both classes, the four target students worked together as a collaboration group. Both teachers walked around the classrooms scaffolding student groups one-by-one. Additionally, they gave whole class instructions to orchestrate the course of the lesson.

To analyze the gaze data, we used ELAN software. Using gaze targets and dwell times as coding units, we annotated the gaze data during the collaborative phases of lessons. Dwell time means the duration of one gaze at a certain target, (Holmqvist et al., 2011) such as a student face, and offers us information on the distribution of a person's visual attention. Further analysis was conducted on IBM SPSS and Microsoft Excel. The face-targeted gazes from the same lessons were synchronized and categorized into four categories. The categories were 1) *Teacher gaze at student face*, 2) *Teacher-started dyadic eye contact*, 3) *Student-started dyadic eye contact*, and 4) *Student gaze at teacher face*. We chose this analysis to explore the amount of reciprocal nonverbal interaction between teachers and students and these categories to chart the initiative roles of this interaction. We also compared the gaze data with the transcribed stationary video data from the lessons to form qualitative and quantitative descriptions. From the classroom videos, we separated the moments of teacher instructions to the whole class from moments of scaffolding with collaboration groups of two to four students. In this report, we analyze these variables of face-targeted gazes and teacher interaction descriptively.

## Results

The teacher-student interaction differed between Joanne's and Fred's lessons despite the similar problem task and lesson structure. Joanne's students seemed more motivated and the atmosphere in class was warm and supportive throughout the lesson. Fred's students expressed more negative emotions, but also enthusiasm and joy of learning. The Figure 1 shows all the individual face-targeted gazes across the collaborative phase in Joanne and Fred's lessons.

**Figure 1** Face-targeted gazes during the collaborative problem solving sessions. The moments of whole-class instructions marked with blue squares and the phases of small-group scaffolding with green circles. The horizontal axis shows the beginning time of the gazes (seconds from the beginning of the lesson) with the frequency of 0.5 seconds and the vertical axis (1-4) the division into four categories: 1) teacher gaze at student face, 2) teacher-started dyadic eye contact, 3) student-started dyadic eye contact, and 4) student gaze at teacher face.

During collaborative problem solving phase, Joanne instructed the whole class more than Fred. In these moments, Joanne gave the students information and instructions on the progress of the lesson. During Joanne's problem solving phase, 63% ( $n = 149$ ) of gazes occurred during whole-class instructions, while in Fred's class the proportion was only 4% ( $n = 13$ ). While instructing, Joanne looked at her student's faces 88 times, even though the instruction moments covered only four minutes of the 16-minute-long collaboration phase.

During whole-class instructions, the target students looked at Joanne's face 20 times, and dyadic eye contacts between students and Joanne occurred 41 times, thrice with the target group. Fred gazed at his students' faces only five times and they looked at him twice without eye contact. Dyadic eye contacts occurred six times between a student and Fred during whole-class instructions but none of these was with a target student.

In Fred's class, the proportion of dyadic eye contacts was higher during the short moments of whole class instructions (46%,  $n = 6$ ) than in Joanne's class (27%,  $n = 41$ ). When giving whole-class instructions, Joanne spoke with loud voice and stood in front of the class. In these moments, the students' tendency to create or respond to dyadic eye contacts with the teacher decreased. In Fred's class, the interaction during collaborative problem solving phase happened almost completely in scaffolding interaction with student groups and he did not seek for capturing the attention of the whole class while the students were working on the task.

Figure 2 presents the distribution of four types of face-targeted gazes between the teacher and target students. Again, the gazes are categorized according to the direction between the teachers and students, and compared between interactional categories of whole-class instructions and scaffolding.

**Figure 2 The distribution of teacher and student face-targeted gazes during two collaborative problem solving session with teachers called Joanne and Fred.**

During scaffolding the target group, the eye contacts distributed similarly with both teachers. The observed four girls in Joanne's class and three boys in Fred's class gazed at their teachers more than other way around. While the teachers focused on one student's solutions or face at the time, the other three or two students often gazed at the teacher. Student gazes at teacher faces covered 44% ( $n = 22$ ) of face-targeted gazes during scaffolding interaction in Joanne's class and 48% ( $n = 60$ ) in Fred's class. The teachers seemed to have different intentions for the scaffolding interaction than the students. While the teachers' intention in the group varied between the problem-solving process and the motivational and emotional states of the students, students were willing to focus on the teachers as they arrived to the groups. The teachers' arriving to the group seemed to capture students' attention and pause their problem solving process. During verbal communication, the students often looked the teacher in the face even if the teacher was looking at and talking about the solutions.

While scaffolding other small-groups than the target group, Fred (74%,  $n = 131$ ) scanned the students with one-way teacher gaze more often than Joanne (41%,  $n = 15$ ) and Joanne had more dyadic eye contacts with students in other groups (54%,  $n = 20$ ) than Fred did (23%,  $n = 41$ ). In general, Joanne's students were more motivated and less frustrated than Fred's students and he had to be more critical in the interaction with them. In Joanne's classroom, the interaction throughout the problem solving process was warm and immediate, while Fred's lesson included also negatively loaded communication. However, Fred's class also included students who were concentrated in solving the challenging task, and hence not in need of the teacher's scaffolding.

In Fred's class, also the teacher's emotional state seemed to affect his gaze behavior. In the beginning of the collaborative phase, the target students joked at Fred, and they were not enthusiastic to solve the problem throughout the lesson. The uncertainty and pauses in Fred's speech in this moment

indicated that this event annoyed or embarrassed him and he avoided eye contacts with these students. After the confusion, Fred told the students to concentrate and continued scaffolding successfully. During scaffolding, three moments occurred, during which the target students tried to create an eye contact with Fred unsuccessfully. They directed several gazes ( $n = 14, 8$ , and  $8$ ) at Fred's face without receiving any response. During these moments, Fred guided them with verbal interaction but directed his gaze at student papers. Interview with him indicates that this aversion was more of pedagogical than purely emotional origin, as Fred wanted to calm the students and behave as an authority.

## Discussion

Orchestrating collaborative instruction and classroom interaction is a complex and challenging task that is affected by various different factors (Prieto et al., 2017). The educational research field has rapidly adopted mobile gaze tracking as a method of data collection in real learning contexts. The use of multiple gaze tracking opens unexplored aspects of micro-level teacher-student interaction. In this paper, we have moved towards capturing the social nature of teaching and learning by using multiple gaze trackers simultaneously.

To summarize the results, the teachers' gaze behavior seemed to vary more depending the interactional state than the students' did. The students looked their teacher in the face both during whole-class instruction, and when the teachers were scaffolding the small-groups. This seems to be a result of teachers' social status and high agency in the classroom (Mehrabian, 1972). Even though collaborative problem solving is a student-centered learning method, the teacher's contribution in orchestrating the learning process is essential (Cross, 2009). The students need teacher's guidance, advice, and confirmation, which she can offer through eye contact and verbal instruction.

However, the teachers, especially Joanne, focused on her students' faces during whole-class instruction moments. In these moments, she looked at her students with numeral, short gazes. This finding is in line with the literature on teacher orchestration load (Prieto et al., 2017) and expertise (McIntyre et al., 2018). When speaking in front of the class, regardless of the content of the instructions, Joanne concentrated in addressing her message through direct gazes at student faces.

In Joanne's class, the target group was located closer to the front of the classroom, while in Fred's class the target students were seated in the back. As Cardellino et al. (2017) suggest, this may affect to the count of eye contacts between the students and the teachers. In Fred's class, no dyadic eye contacts were formed between him and the target students when Fred was standing in the front. Additionally, Fred's target students were not as motivated in solving the task as Joanne's were, and he may have unconsciously directed his instructions to those students he knew were waiting for them.

When changing the interactional state from whole class to a collaboration group, we found general characteristics in the gaze behaviors of teachers and students. The teachers were in the locus of students' attention in all interactional moments. While in whole class interaction the teacher's attention distributes unevenly (Dessus et al., 2016), we interpret that in small-group scaffolding moments all kinds of students had an opportunity to be seen and heard. Despite their misbehavior, the target students in Fred's class pursued his attention. Fred seemed to avoid dyadic eye contact with them after the confusions to act as an authority and direct their attention to the learning task.

Naturally, this exploratory study has certain limitations. First, the missing data (one student gaze recording and one teacher interview) and the differences in the counts of gazes between the lessons hinder the comparative interpretations. However, this is a case study, and all the comparisons are qualitative by nature. Their purpose is to chart the phenomena for more statistical analysis in the future. For instance, in this report the student groups happened to be of same gender as their teachers. In this analysis, the attentional patterns were quite similar between the two lessons. In future, the effect of altering the gender structure of the participants might be relevant to investigate. The quality of the gaze and video data was very high, which helped us in making analysis and interpretations. Each recording was annotated by only one researcher. Nevertheless, the research group negotiated on controversial issues during the annotation and interpreted the data collaboratively.

This study shows that adding student gaze data to teacher gaze data reveals aspects that would not be possible to be explored with only one gaze tracker. For instance, students' unsuccessful attempts to create eye contacts with the teacher and vice versa are indicators of the complexity of teacher-student verbal and nonverbal interaction. In future, we wish to examine more how teacher-student eye contacts are affected by aspects emerging in this analysis: the teacher and student personalities, methods of teacher-student interaction, and the physical learning environment.

### Acknowledgments

We would like to thank Jessica Salminen-Saari and Tran Phuoc for their contribution in collecting, organizing and annotating the data. This research is a part of MathTrack project that is funded by the Academy of Finland (grant 297856).

## Collaborative processes when reasoning creatively about functions

Ellen Kristine Solbrekke Hansen

Norwegian University of Life Sciences, Faculty of Science and Technology, Norway;  
[ellen.hansen@nmbu.no](mailto:ellen.hansen@nmbu.no)

*Keywords: Collaborative processes, creative reasoning, function problems.*

As observed for the last 50 years, students in upper secondary school struggle with the function concept (Dubinsky & Wilson, 2013). The function concept can be represented in different ways, for example as a graph, a table, or an algebraic expression. Translating from one representation to another, transforming a situation into a function, and discovering the function notation are important for students' ability to "describe relationships of change between variables, explain parameter changes, and interpret and analyze graphs" (Clement, 2001, p. 745). Students' exploration and engagement in making connections, for instance among different function representations, is important for understanding mathematical concepts and for learning to apply it as a tool in problem solving (Francisco & Maher, 2005; NCTM, 2014). In a student-centered environment with focus on collaboration, students have the opportunity to investigate, share and evaluate each other ideas. Research on mathematical communication, supporting students' collaborative activity and reasoning, is crucial for students' mathematical understanding (Maher, Sigley, Sullivan, & Wilkinson, 2018; Mueller, Yankelewitz, & Maher, 2012).

Lithner (2017) defines reasoning as "the line of thought adopted to produce assertions and reach conclusion in task solving" (p. 3), and proposes two main types of reasoning while solving a mathematical problem: imitative and creative. Students' reasoning do not have to be formal, a mathematical proof or a high-quality argument, it simply has to make sense to the student himself (Lithner, 2015). Creative mathematical reasoning (CMR) sequences are created (or re-created) by the student, plausible to him, and anchored in intrinsic mathematical properties (Lithner, 2015). Imitative reasoning, on the other hand, refers to imitating a solution procedure or memorizing facts (Lithner, 2015). Imitative reasoning is closely linked to rote learning, whereas creative reasoning to a larger extent will promote conceptual understanding (Lithner, 2017). Roschelle and Teasley (1994) define collaboration as a "coordinated, synchronous activity that is the result of a continued attempt to construct and maintain a shared conception of a problem" (p. 70). If mutually engaging in problem solving "students share ideas and ways of solving problems; thus individual understanding becomes shared" (Mueller et al., 2012, p. 372). Creating a shared understanding between collaborating students, is what Roschelle and Teasley (1994) call a Joint Problem Space (JPS). Constructing JPS is processes of building (suggesting and agreeing upon ideas), monitoring (questioning and explaining ideas) and repairing (negotiations and corrections of conflicting ideas), through the use of language and the situation (Roschelle & Teasley, 1994).

There are many theoretical frameworks for analyzing students' difficulties with the function concept, but not corresponding literature providing pedagogical strategies helping students overcome these difficulties (Dubinsky & Wilson, 2013). The current ongoing research project focuses on both student-student interaction, as well as the interaction between the student and the teacher. In line with Design-Based Research (DBR) methodology, three teachers and their mathematics students (age 16)

from a Norwegian upper secondary school participated in an iterative cycle for testing and developing an intervening design (Juuti & Lavonen, 2006). In the student-student interaction, the aim is to provide insight in the collaborative processes when reasoning about a function problem. Combining such insight with perspective on teacher-student(s) interaction, could give further insight to pedagogical strategies for promoting students' reasoning in collaboration, for deeper understanding of mathematical concepts.

This paper poster will illustrate a student-student interaction in a pair creating their JPS through processes of building, monitoring and repairing, when engaging in creative mathematical reasoning. Particularly, different aspects in their argumentation connected to the process of repairing their shared understanding. Some periods in their conversation were identified as CMR-sequences, characterized by turn-taking and creative mathematical reasoning solving a part of the function problem. However, not every uttering in the turn-taking was identified as creative. In situations where students had conflicting ideas, they often argued for their thoughts. Students used superficial arguments to support ideas, as well as arguments built on mathematical properties. If a counter-suggestion was made, without any support, and conflicting the other students' idea, the following process was significant. If only accepting the counter-suggestion, they were not likely to explore different representations and deeper meaning of the function concept together. Thus, experiencing ownership in the problem solving process, or over the mathematical content, was not likely to happen. If not agreeing on the counter-suggestion, the peer could ask questions about the idea, or make a counter-suggestion. Anchoring the counter-suggestion, question or suggestion in properties regarding the function concept, were important for the process of creating the JPS. Hence, repairing of the shared conception of the problem, or sub-problem, indicated to a greater extent mutual ownership.

# What can metaphor tasks offer for exploring preservice mathematics teachers' beliefs?

Çiğdem Haser

University of Turku, Faculty of Education, Finland; cigdem.haser@utu.fi

*The purpose of this study was to investigate preservice middle school mathematics teachers' (PMT) beliefs about the nature of mathematics in metaphor tasks when they are designed and analyzed in different ways and their beliefs about mathematics teacher. Nine PMTs attending the practice teaching course completed four metaphor tasks (two open-ended, two structured) about mathematics, mathematics teacher, mathematics teaching and learning through the semester. The metaphors they produced were analyzed both by the revised version (Löfström et al., 2010) of the identity framework by Beijard et al. (2000) and with an inductive analysis. Findings suggested that employing open-ended task structure and inductive analysis might provide more information about PMTs' beliefs about the nature of mathematics even in metaphors that are not constructed for mathematics.*

*Keywords: Metaphors, beliefs about mathematics, preservice middle school mathematics teachers.*

## Metaphors and beliefs

Metaphors are the constructs that are used to explore one concept/happening/issue by the help of another (Lakoff & Johnson, 1980) and are used to interpret the complexity of teaching and learning interaction components (Saban, 2006). Metaphors are among the tools that enable teacher educators have access to and explore the preservice teachers' beliefs (Reeder, Utley & Cassel, 2009). Researchers have often asked preservice teachers about their metaphors especially about teaching and learning to make sense of their beliefs and their implicit theories about education (Leavy, McSorley, & Bote, 2007). Metaphors are also used in teacher education programs to make preservice teachers reflect on their beliefs (Noyes, 2006) and to increase their awareness of their beliefs and teacher selves, to build connections between these selves and teaching, and further to change their beliefs (Saban, 2006).

Several studies have explored preservice (Haser, Arslan, & Çelikdemir, 2015) and inservice (Oksanen & Hannula, 2013; Pantziara, Karamanou, & Petridou, 2017) mathematics teachers' beliefs about mathematics teacher through metaphors by using the framework developed by Löfström et al. (2010) based on the identity framework of Beijard, Verloop and Vermunt. (2000). Beijard et al. (2000) suggested three teacher identity categories as *subject matter expert*, *pedagogical expert* and *didactical expert*. They explained that teacher as a subject matter expert knows mathematics well and transmits this knowledge to the students. Teacher with a pedagogical expertise cares about students' well-being and their growth as a person. When teachers are didactical experts, they organize teaching and learning environments to guide students in their learning efforts. Löfström et al. (2010) further suggested that teachers have characteristics that do not fit the three identity categories defined earlier as in *self-referential* metaphors, and the *contextual* references to the teacher identity could also be seen in metaphors. The mentioned studies showed that the identity framework could be used to explore preservice and inservice teachers' beliefs about mathematics teacher and what they prioritize

for the work mathematics teachers do. These studies have found that Cypriot teachers of grades 10-12 (Pantziara et al., 2017) and Finnish teachers of grades 7-9 (Oksanen & Hannula, 2013) prioritized didactical expertise for mathematics teachers. Mathematics teachers in these studies addressed self-referential metaphors after didactical expert metaphors. Although these metaphors are likely to address teachers' other mathematics-related beliefs (Haser et al., 2015), such an analysis has not been reported in these studies.

Similarly, when we asked Turkish preservice middle school mathematics teachers (PMTs) to write a metaphor for the mathematics teacher and explain it, they prioritized didactical expertise (Haser et al., 2015). In our unpublished analysis, we found that PMTs referred to the nature of mathematical knowledge, how it is related to other fields of science and that mathematics teachers needed to know about these characteristics of mathematical knowledge, while explaining their metaphors for mathematics teacher. Such reference to the nature of mathematics suggested adopting an inductive approach to the analysis of metaphors' explanations in order to trace PMTs' beliefs about the nature of mathematics, even when these metaphors were not constructed for mathematics.

Considering the findings of previous studies, which explored preservice and inservice teachers' mathematics related beliefs through metaphors, the purpose of this study was to investigate what metaphors can offer for understanding PMTs' mathematics related beliefs, and specifically beliefs about the nature of mathematics, even when they were not constructed for mathematics. The study also explored the change in PMT's beliefs about mathematics teacher. PMTs' explanations for metaphors, which were used in a practice teaching course as a reflection tool, were analyzed by the above-mentioned revised identity framework and by inductive analysis to explore PMTs' beliefs.

## Method

The study was conducted in a middle grades (5 to 8) mathematics teacher education program in Turkey. All nine (female) PMTs attending the practice teaching course section that I taught were the participants of the study. PMTs have completed mathematics teaching methods courses and school experience course, and they were in the last semester of the program except for one student who had two more courses to take. They attended the same practice school for six hours each week, observed several mathematics teachers during the semester, completed emerging tasks in the school, and taught mathematics for at least one class hour. They also attended two hours of University course that I taught every week and discussed the emerging themes and issues of the week from the mathematics lessons they observed, and completed in-class tasks such as constructing metaphors and their explanations for mathematics related themes. The data of the study were PMTs' responses to the four metaphor tasks they completed during the class hours (50+50 minutes) and the detailed course notes that I kept during the course. Table 1 presents the content of the metaphor tasks used in the study through the semester (15 weeks).

Task 1 and Task 2 were considered as *open-ended tasks* because PMTs were only asked to construct a metaphor and explain it, and they were not asked to consider this in a certain way. Task 3 and Task 4, however, were considered as *structured tasks* because PMTs were asked to select one theme, construct a metaphor for it, then think about relationships of this theme to the others, and construct metaphors for these themes.

Tasks and weeks	Content of the metaphor tasks
Task 1 (1 <sup>st</sup> week)	Math teacher is like ..... Because..... Math teaching is like .....Because .....
Task 2 (2 <sup>nd</sup> week)	Math is like ..... Because .....
Task 3 and Task 4 (3 <sup>rd</sup> week and 15 <sup>th</sup> week)	Choose a starting theme (math, math teacher/teaching/learning) and construct a metaphor for this theme. Then, connect it to the remaining themes by constructing related metaphors for them. Please explain the relationships.

**Table 1: Metaphor tasks**

Initial data analysis focused on the explanations for mathematics teacher metaphors to reveal PMTs' beliefs about mathematics teaching by employing the revised framework. Then, I conducted an inductive analysis (Miles, Huberman, & Saldana, 2014) for all metaphor explanations in order to explore PMTs' beliefs about mathematics. First, I read all the explanations for metaphors in detail and took notes on possible codes such as, mathematics in daily life and connectedness of mathematical knowledge. Next, I went through data once more and coded the data with the code list I developed with room for possible new codes such as, mathematics-related skills. The analysis was completed after no new codes were generated and all data were analyzed with all the codes. The metaphors themselves were not the focus of the analysis because there were several cases that PMTs explained the same metaphor in different ways throughout the tasks. Or, they used different metaphors in each of the tasks for mathematics teacher and still referred to the same teacher expertise in their explanations for these metaphors. Therefore, the focus of the analysis was on PMTs' explanations for their metaphors.

## Findings

First, findings related to the mathematics teacher expertise that PMTs prioritized are presented. Then, findings about beliefs about the nature of mathematics extracted from PMTs' explanations for all the metaphors were presented for each metaphor task. Metaphors PMTs used are reported briefly.

### Beliefs about mathematics teacher through the semester

PMTs wrote a metaphor for mathematics teacher and the explanations for their metaphors in Task 1, Task 3 and Task 4. The analysis of the explanations for their mathematics teacher metaphors through the revised framework is given in Table 2. The types of expertise identified in the metaphor explanations are indicated by "D" for didactical expert, "SM" for subject matter expert, "P" for pedagogical expert, and "SR" for self-referential as indicated in the revised framework.

PMTs prioritized didactical expertise (cook, driver, pine tree) for mathematics teachers. Almost all participants in all tasks explained how a mathematics teacher is a didactical expert. PMT6 and PMT9 addressed only didactical expert in their explanations in all three tasks and PMT1, PMT5 and PMT8 prioritized other expertise (mostly subject matter) in their explanations in addition to the didactical expertise. PMT2, PMT3 and PMT4 addressed didactical expertise in two of the three tasks and PMT1,

PMT5 and PMT7 addressed subject matter expertise (calculator manual, tour guide) in their explanations for two of the three tasks.

Participants	Task 1	Task 3	Task 4
PMT1	D, SM	D	D, SM
PMT2	D, P	D	SR
PMT3	D, SR	SR	D
PMT4	P	D, SM	D
PMT5	D, SM	D, P	D, SM
PMT6	D	D	D
PMT7	SM, SR	SR	D, SM
PMT8	D, SM	D	D
PMT9	D	D	D

**Table 2: Participants' identities as determined in the metaphors about mathematics teacher**

These findings showed that in the beginning of the semester PMTs tended to believe that mathematics teachers were mostly didactical experts. This focus on teachers' didactical expertise increased as the semester progressed. They also addressed subject matter expert, self-referential and pedagogical expert identities. Hybrid metaphors mostly included didactical and subject matter expertise, and did not include more than two expertise. Context did not appear in PMTs' metaphors.

#### **Mathematics in mathematics teacher and mathematics teaching metaphors (Task 1)**

Five PMTs mentioned about the nature of mathematics in their explanations of the mathematics teacher metaphor. Mathematics is discovered by the help of the teacher (PMT1, PMT6) who also guides for other skills such as "*problem solving, critical thinking*" (PMT9) and building connections between mathematics, daily life and other sciences (PMT5).

Seven PMTs mentioned about the nature of mathematics while explaining the mathematics teaching metaphor (using magnifying glasses, making the light available for everyone). There were references to mathematics in real life (PMT3, PMT5, PMT6) and mathematics related skills such as "*interpreting the world differently*" (PMT3). Teaching mathematics was also framed in terms of characteristics PMTs associated with the nature of mathematics such that it can be discovered (PMT1, PMT3), it includes connections (PMT8), and it is expanding (PMT3, PMT9).

Most of these PMTs stated in their explanations that since mathematics has certain characteristics, mathematics teacher or mathematics teaching must be in a certain way. Some even constructed a metaphor for mathematics for the explanation first, and then framed mathematics teacher or teaching based on this metaphor. Even though mathematics was a beginning point for most PMTs, the teacher and teaching metaphors they constructed seemed disconnected in Task 1, such as P9's metaphor for mathematics teacher (bitter syrup for students) and teaching (filming an advertisement).

### Mathematics in mathematics metaphors (Task 2)

PMTs' explanations for their metaphors about mathematics (the code for existence, atmosphere, infinite chain of paper-clips) emphasized the necessity of mathematics in daily life (PMT6, PMT7, PMT9). Besides, mathematics is fundamental to understanding the life, the nature, and the other sciences (PMT2, PMT3, PMT6). Therefore, mathematics is important and needed (PMT2, PMT6, PMT9). PMT5 mentioned about the infinite nature of the mathematical knowledge. Only PMT9 emphasized that we use skills such as “*understanding situations, problem solving, foreseeing causes [and related] consequences, or evaluating*” while doing mathematics. PMT8 used “*being an explorer*” as a metaphor for mathematics and emphasized that mathematical knowledge is discovered or newer ways of reaching mathematical knowledge are discovered.

### Mathematics in mathematics related metaphors – 1 (Task 3)

Task 3 and Task 4 asked PMTs to select one theme, construct a metaphor for that theme, and then continue to construct metaphors for the other themes. Eight of the PMTs started with a metaphor for mathematics in Task 3. Then, seven of them continued with either mathematics teacher or mathematics teaching themes. PMT4 started with mathematics teacher, continued with mathematics and then, with mathematics teaching.

The explanations for mathematics metaphors (flower, second mother tongue, fruit tree) emphasized that mathematics is fundamental to life and other sciences and humanity needs mathematics (PMT6, PMT9). Mathematics concepts are related to each other:

Mathematics is like chess. Because mathematics has rules, theorems and formulas [...] related to each other and all of those compose mathematics. Chess also has certain rules, strategies; and since there are relationships between strategies and more explicitly, since [strategies] change based on each move, mathematics is like chess. (PMT1)

There is always something to discover in mathematics (PMT9), it promotes analytical thinking (PMT2), and we always come across mathematics in our daily lives (PMT2, PMT6, PMT7, PMT9).

Metaphors about mathematics teaching and mathematics teacher did not reveal beliefs about mathematics in Task 3. Only PMT1 referred to the new ways to reach mathematical knowledge in her metaphor for mathematics teacher and PMT8 emphasized that mathematics helps us develop real life relationships in her explanation for her metaphor for mathematics teaching.

### Mathematics in mathematics related metaphors – 2 (Task 4)

Similar to Task 3, all participants except PMT4 started Task 4 by constructing a metaphor for mathematics, and they continued with a metaphor for the mathematics teacher or mathematics teaching. This time, PMT4 started with a metaphor for the mathematics teaching, and then continued with mathematics and mathematics teacher.

Metaphors for mathematics (second mother tongue, water, endless travel) addressed that mathematics is an expanding field and it is infinite (PMT2, PMT3, PMT7). It is fundamental to life like “*the atmosphere. Atmosphere covers the earth and it is important for life*” (PMT6) and human beings need

it. Similarly, they need mathematics. It improves and changes our ways of thinking (PMT9) and it is in our everyday life (PMT5, PMT6, PMT9).

Only PMT9 wrote about discovering mathematical concepts in her metaphor for mathematics teacher and PMT5 stated that mathematics is in our daily life. PMT9, in her metaphor for mathematics teaching, referred to the skills that (knowing) mathematics provides, the coherence among the mathematical concepts and that human beings need mathematics.

PMTs realized that they could not connect their metaphors about mathematics, mathematics teacher and mathematics teaching all the time and claimed that this was challenging in both Task 3 and Task 4. They did not prefer to state metaphors for mathematics learning in Task 3 and Task 4. The metaphor explanations did not refer to students most of the time.

## **Conclusions and discussion**

The analysis of explanations for the mathematics teacher metaphors showed that most of the PMTs seemed to prioritize teachers' didactical expertise, most probably due to spending considerable time in the practice school and program's emphasis on improving didactical skills (Haser et al., 2017) especially in the last semester. This didactical expertise emphasis and explanations for mathematics teaching metaphors included several references to the nature of mathematical knowledge.

PMTs expressed very similar beliefs about mathematics across the tasks and these beliefs did not change much as the semester progressed. Mathematics was at the center of real life and other sciences. Therefore, humanity needed mathematics. Knowing or being able to do mathematics provided several skills such as problem solving and analyzing complex situations better. Mathematical knowledge was expanding and it could be discovered. These beliefs were not only in their metaphors for mathematics, but also in their metaphors for mathematics teacher and teaching in Task 1, and they did not change from the beginning to the end of the semester, suggesting that these beliefs might be held by the PMTs more strongly.

Inductive analysis of open-ended metaphor tasks about mathematics teachers and teaching provided more clues about PMTs' beliefs about the nature of mathematical knowledge when the metaphors were not constructed for mathematics in Task 1. However, the metaphors for mathematics teacher and teaching in Task 1 were very disconnected even though these metaphors were asked in the same task. This disconnectedness might have led them towards describing the nature of mathematical knowledge in all the metaphor explanations to provide a base for framing their metaphors for teachers and teaching. This, in turn, provided more clues about PMTs' beliefs about the nature of mathematics and suggested that these beliefs could be the base for their beliefs about mathematics teaching and teacher. It might also be the case that PMTs' beliefs about the nature of mathematics are persistent but their beliefs about mathematics teachers, teaching and learning are still under construction. Therefore, they might prefer to build their metaphors for teacher and teaching around mathematics metaphors and explanations.

PMTs preferred to start the structured tasks in Task 3 and Task 4 by first constructing a metaphor for mathematics, and then the others. These findings might address that even when PMTs prioritize didactical expertise for mathematics teachers, their beliefs about the nature of mathematics might be

at the center of their beliefs about a mathematics teacher and teaching. They might be building an understanding of the work of mathematics teacher and the duties of mathematics teaching around how they believed about the nature of mathematical knowledge.

PMTs' explanations for mathematics teacher and mathematics teaching metaphors in structured tasks in Task 3 and Task 4, on the other hand, rarely referred to the nature of mathematical knowledge. Starting the structured tasks by first constructing a metaphor for mathematics, and then connecting this metaphor with the metaphors for other themes without referring to the nature of mathematics might indicate that they already have constructed the metaphor for mathematics and this provided them with the necessary base for their metaphors for mathematics teacher and teaching.

There were very few mathematics learning metaphors even though PMTs were encouraged to construct in Task 3 and Task 4. The explanations for other metaphors rarely referred to the students, most probably due to focusing more on the teachers in the practice school.

In both types of metaphor tasks, the theme-metaphor-explanation flow did not seem coherent in many cases. Mathematics, for example, was addressed with verb metaphors, such as "*playing chess*", and mathematics teaching was addressed by noun metaphors, such as "*gossip*." PMTs seemed to describe one theme while actually explaining another. Such incoherence might show that PMTs were confused about the properties of the metaphors while they were trying to construct them. Indeed, field notes indicated that PMTs struggled and spent considerable effort and time to construct metaphors and explanations, although all tasks included information about metaphors and their functions. We discussed through the semester about how metaphors would help them to think deeply and increase their awareness about the issues of teaching mathematics. Yet, they had difficulties in finding metaphors in at least one task. They wrote detailed explanations that did not always fit the metaphor.

Why not asking directly about PMTs' beliefs but asking metaphors instead? Constructing a metaphor for a concept requires thinking about the characteristics of the concept in order to find a metaphor object, which shares similar characteristics with the construct (Saban, 2006). This process might direct PMTs to think about details, connections, and relationships more deeply than responding to a direct question. In this study, the inconsistencies between metaphors and explanations might indicate that PMTs are still struggling with building these concepts or have realized the complexity of these concepts and have difficulties in finding a metaphor for such complexity. Therefore, metaphors might be a powerful tool to reveal PMTs' such incomplete processes for teacher educators and to increase PMTs' awareness of their thinking process.

Although the actual metaphors were not the major focus of the present report, it appeared that PMTs' metaphors resembled similarities to the ones reported in the literature such as mathematics as a language, journey, structure and toolkit (Noyes, 2006) and mathematics teaching as a journey and growth (Reeder et al., 2009). A further analysis is needed to explore these metaphors.

Findings of the study showed that different uses and analyses of metaphor tasks might provide different ways of exploring PMTs' mathematics related beliefs. However, the findings are limited to the nine PMTs who participated in this study, the metaphors and explanations they constructed, the ways metaphors were asked and written data. They expressed difficulty in constructing a metaphor and the need to know the properties of the metaphor object to construct it better. Therefore, the key

issues in employing metaphors as tools of reflection in teacher education might be helping PMTs focus on connectedness and coherences of their ideas, reflect more on their beliefs, and their willingness to adopt and use metaphors in this process.

*This paper presents a thematic analysis methodology which uses a hybrid coding process to understand how science and engineering students in higher level education relate to mathematics. This process utilises and builds on previous research on mathematical identity amongst student teachers by using deductive coding while continuing to be grounded in the new data through inductive coding. Many authors have written on both or either of these methods. Most treat it as a simple choice between one or the other. Few have addressed best practice in integrating these approaches.*

*Keywords: Mathematical identity, transition, higher level education, thematic analysis.*

## **Introduction**

To create an effective learning environment for science and engineering undergraduates, an awareness of how they relate to mathematics is vital. Investigating mathematical identity can help educators better understand this relationship and help determine potential issues with pedagogy and the learning experience of students. Such issues may contribute to marginalisation and thus impact students' relationship with mathematics and their decision to continue, or not, their mathematical studies (Grootenboer & Zevenbergen, 2008; Solomon, 2007). Reflecting on their mathematical identity can help students engage more effectively as mathematics learners while they transition to higher level education (Kaasila, 2007). In the same vein, Sfard and Prusak (2005, p. 16) suggest that “identity talk makes us able to cope with new situations in terms of our past experience and gives us tools to plan for the future.”

Mathematical identity has been investigated in the context of Initial Teacher Education in Ireland since 2008. A series of previous studies developed an instrument for exploring mathematical identity of pre-service teachers which has been adapted for this new context. The ‘Mathematical Identity of Student Teachers’ (MIST) study used grounded theory among 9 students to develop two open-ended questions: a broad opening question to allow participants make responses that are “indicative of their personal mathematical identity” and a follow-up question which included some prompts “to balance the need for some direction” (Eaton & O'Reilly, 2009, p. 2). ‘Mathematical Identity using Narrative as a Tool’ (MINT) involved 99 students and not only converted the questionnaire to an online tool but also added a third question about self-reflection which had become evident as a key element of mathematical identity in MIST (Eaton, Horn, Liston, Oldham, & O'Reilly, 2013).

Although mathematical identity has enjoyed increased attention in recent years within education (Darragh, 2016), a lack of cohesion and agreement on ontological, epistemological, and methodological issues has produced a fractured body of research (Kaspersen, Pepin, & Sikko, 2017b). Despite this new attention, Hannula and Garcia Moreno-Esteva (2017) found that identity had featured in just four of 100 papers in this working group (TWG8) between CERME4 and CERME9.

At CERME10 Kaspersen, Pepin, and Sikko (2017a) in TWG20 focused on the link between mathematical identity and grades much like Cobb, Gresalfi, and Hodge (2009) did. A study by Craig (2013) took a narrower view of identity, thinking only of procedural versus conceptual learning, ignoring the many other facets of identity that interact with this specific strand. In Ireland, MIST/MINT (Eaton & O'Reilly, 2009; Eaton et al., 2013) focused on developing an instrument to collect narrative data, but the process of analysing this data requires some clarification in order to be reliably used in other contexts or amongst larger groups of students. Although some studies have investigated engineering identity, and incidentally addressed mathematics, studies dealing with the mathematical identity of engineering students are rare.

This paper will outline how we adapted and integrated inductive and deductive techniques to facilitate a thematic analysis. This addresses the need to incorporate the knowledge gained from previous work on mathematical identity in Ireland while also continuing to be grounded in the new data. We refined the MIST/MINT coding process by deconstructing the themes they developed amongst student teachers (which may not accurately represent the mathematical identity of this new cohort) into codes and constructed new themes based on the current data. We will demonstrate how the coding process aided the thematic analysis, already established in MIST/MINT, for cohorts of students not previously considered there. We expect this to advance the drive toward an effective process for accessing students' mathematical identities.

## **Background and Theoretical perspective**

Sfard and Prusak (2005) and Kaspersen et al. (2017a) both noted that researchers in mathematics education had yet to agree upon a working definition of identity while Cobb et al. (2009, p. 41) conceded that it is “vague and ill-defined.” Authors often operate from different viewpoints: the sociological viewpoint where identity is an action, constructed and reconstructed over time, which has long characterised identity at CERME (Hannula & Garcia Moreno-Esteva, 2017), and the psychological viewpoint where identity is a core stable phenomenon (Cobb et al., 2009). Sfard and Prusak (2005) detailed the similarities between identity and other concepts such as attitudes, conceptions and beliefs but pinpointed the constantly changing and evolving nature of identity as the key power behind the concept. The sociological viewpoint of identity acknowledges that it is ever-changing and communicated best through narratives authored by the participants. They can communicate mathematical experiences they consider to be influential and reflect on them as they write often leading to realisations or re-interpretations of the experiences.

This study is conducted under a social constructivist paradigm and mathematical identity is defined as the “multi-faceted relationship that an individual has with mathematics, including knowledge, experiences and perceptions of oneself and others.” (Eaton & O'Reilly, 2009, p. 228; See also Grootenboer & Zevenbergen, 2008) We propose that empirical information about experiences is not enough to reveal mathematical identity and we aim to establish the meaning of these experiences from the views of participants (Creswell, 2009, p. 16). We follow the narrative approach detailed by Creswell (2009, p. 13) whereby the narrative produced by the research represents a repackaging of the experiences and stories communicated by the participants. The resulting narrative represents a

combination of these experiences with those of the researcher, positioning the participants as co-researchers who shape the research process (Cohen, Manion, & Morrison, 2007, p. 37).

## Methodology

We identified 16 cohorts of science and engineering students in DCU who study mathematics in their first year. They represent a significant portion of the undergraduate population and of students taking mathematics modules, but they have not previously been included in research on mathematical identity. Participants were recruited in lectures where the lead author explained the study, distributed plain language statements and returned one week later to voluntarily sign up students who were interested in taking part. An online questionnaire (adapted from MIST/MINT) consisting of three open-ended questions was employed with each question appearing on a separate page. A pilot study conducted in Winter 2017 involved 18 respondents (10 science and 8 engineering students). There were 32 respondents to the main study (22 science and 10 engineering students), contributing a total of 8000 words. The first two questions are the focus of this paper and are presented in Figure 1. Note that third level is an Irish term for higher level education.

Q1. Think about your total experience of mathematics. **Tell me about the dominant features that come to mind.**

Q2. Now think carefully about all stages of your mathematical journey from primary school to university mathematics. Consider:

- Your feelings or attitudes to mathematics
- Influential people
- Critical incidents or events
- Specific mathematical content or topics
- How mathematics compares to other subjects
- Why you chose to study a course which includes mathematics at third level

**With these and other thoughts in mind, describe some further features of your relationship with mathematics over time.**

**Figure 1: First two questions of the online questionnaire which were presented on separate pages**

To analyse the open-ended responses to the online questionnaire we used a hybrid process of inductive (data-driven) and deductive (theoretical) coding adapted predominantly from Fereday and Muir-Cochrane (2006) with influence from Braun and Clarke (2006), Boyatzis (1998) and Crabtree and Miller (1999). The latter authors noted that codes “can be constructed a priori, based on prior research or theoretical perspectives or created on preliminary scanning of the text” and that “...some initial codes are refined and modified during the analysis process.” (p. 167) Their claim that constructivists tend to lean towards co-created codes fits well with Braun and Clarke's categorisation of thematic analysis as “grounded theory ‘lite’” (Braun & Clarke, 2006, p. 81) since this research builds on the grounded theory research of MIST/MINT.

Our approach consisted of seven stages (of which, the first four will be described further on):

**Stage 1** Development of codebook from literature review of MIST/MINT and pilot study.

**Stage 2** Code stratified sample of main data.

**Stage 3** Broad reading and summarising of entire data set.

**Stage 4** Code data using inductive and deductive codes. Elaborated in detail below.

**Stage 5** Group codes to develop thematic map.

**Stage 6** Review themes and use the data to check for internal and external homogeneity.

**Stage 7** Define and name themes.

Stages 3-7 broadly align with the five steps suggested by Braun and Clarke (2006) who treated inductive and deductive coding as separate techniques. Stages 1-5 correspond to steps from Fereday and Muir-Cochrane (2006) but with a significantly expanded fourth stage as well as stronger interplay between the data analysis stages. Crabtree and Miller (1999) have a simple four step model (with stages 2-4 combined) which omits the testing stage although they do go on to discuss such a step (p. 168). All authors participated in stage 2 coding but stage 3 and 4 were conducted by the lead author.

Although most authors recommend an iterative line-by-line coding process where codes are developed, applied and immediately examined for groupings without reference to the data (Braun & Clarke, 2006), we realised that the density of these responses (on average every 9 words resulted in a code) meant that it was considerably more difficult to extract meaningful codes from the data in a single round of coding without including multiple perspectives (Strauss & Corbin, 1998). We thus developed stage 4 significantly beyond what is described by other authors. The remainder of this section will describe stages 1-4, which have been completed, with particular emphasis on stage 4. It is intended that Stages 5-7 will follow the recommendations given by Braun and Clarke (2006).

## **Stage 1**

MINT/MIST participants' responses were used to develop seven main categories: self-reflection, influential people, ways of working in mathematics, comparing other subjects, nature of mathematics, right and wrong and mathematics as a rewarding subject (Eaton, Oldham, & O'Reilly, 2011, p. 32). These categories were expanded into codes using the examples and discussion from five MINT papers, three MIST papers (one unpublished) and two papers from an interim 'bridging' study. Codes that did not clearly fit in any of these categories were simply left uncategorised.

The pilot study helped to further demarcate the codes under each category. We followed Fereday and Muir-Cochrane (2006, p. 85) and Boyatzis (1998) by naming the codes, providing a description, some keywords (if possible) and giving at least one example from the pilot study of an instance of the code. From the start we adopted the use of an extra miscellaneous code for items which do not fit any existing category. This step is used to check the comprehensiveness of the codebook and to ensure nothing relevant is overlooked the coding process because it is difficult to categorise. For example:

ID86            I think its good that I'll be practicing something I'm bad at.It means I'll be eventually not so bad at it.

## Stage 2

A codebook consisting of 37 codes was applied to a stratified sample of 8 from the 32 respondents, based on grouping, cohort, gender, word count and age. All three authors coded this data separately. We discussed the results with reference to the codebook and adapted the codebook by splitting, combining or creating codes as appropriate changing the number of codes to 47. The definitions were also updated, keywords added and examples from the sample included in line with the relevant codes. Our initial main coding principles were derived from the sample coding at this stage. They are given here with examples to show their effectiveness:

1. Code in-line by including a number at or near each instance. Codes can run across sentences, overlap and a single statement may require multiple codes.

Pay attention to context between sentences or along entire paragraphs.

ID 118            Physics is about explaining everything essentially, and making sense of everything. That's why maths is interesting to me...

This student talks about making sense of everything but the second sentence makes clear that mathematics also plays a role either intrinsically or in tandem with physics.

2. Codes should be broad enough to allow a range of responses to be grouped. Especially where a continuum exists, e.g., mathematics is exciting/boring or hard/easy.

3. Often participants will express a combination of both positive and negative, e.g., elements they like and elements they don't like or parts they find hard or easy:

ID124            I enjoy certain parts of it.

ID78            Certain aspects came easier to me than others...

ID98            Leaving a hard topic and starting to learn a harder one makes the first hard topic seem very easy.

They may give a 'middle-ground' response:

ID96            Generally ok experience...

ID120           I found mathematics okay.

Students sometimes mitigate their opinions:

ID40            I don't like Maths as a subject but I like doing it.

## Stage 3

The entire dataset was read through for "close contact and familiarity" (Boyatzis, 1998, p. 45) and to make the important first step towards understanding the narratives therein. To accomplish this the data was read through repeatedly, "taking notes or marking ideas for coding" (Braun & Clarke, 2006,

p. 87) as well as noting the key points made by participants (Fereday & Muir-Cochrane, 2006, p. 86). These notes were used later for comparison with coding.

#### Stage 4

To enact the principles stated at the beginning of this section, the coding process consisted of several steps (ways of looking at the data):

- (a) Apply codes using a fine-grained, line-by-line approach.
- (b) Write a summary of each participant's response and compare with the codes allocated.
- (c) Compare with original notes from broad reading of the data.
- (d) Code each 'piece of interest' by removing chunks of text and re-reading them in isolation.
- (e) In tandem:
  - i. Pick each code and read through data for possible extra occurrences of the code.
  - ii. Use keywords to identify possible extra occurrences of each code.
- (f) Interrogate data coded as miscellaneous to determine if re-categorisation is possible.

This resulted in the creation of 20 inductive codes to be reviewed at the next stage. Each step shown above added to the exhaustiveness of the coding by illuminating more opportunities for codes to be applied but was also useful for adding new ideas as notes under each participants' response. Step (a) arose because we found that students' responses contain a lot of information even in short pieces of text:

ID 55            I generally did well in maths exams [*good at maths*] compared with other subjects [*comparing subjects*], which made me enjoy the subject more [*I enjoy maths*], and gave me confidence and a belief that I could do well [*origin of interest in maths*] in the field [*confidence in maths*].

In step (c) almost every initial note had been encapsulated in the coding. Of the remainder, most notes were now either obviously unfounded or involved too high a level of interpretation to be included:

ID 118            ...explaining the reasoning behind what we were learning. We just learned for the sake of learning...

This was initially considered as "I like to understand the content rather than learn it off" which requires a leap of interpretation. It fit much better in the inductive code "Learning/doing maths without knowing why."

In step (e) we discovered that searching for keywords often resulted in hits from the summaries in part (b). This was useful for identifying via a paraphrasing whether the correct codes had been applied. Searching for 'pace' brings up my comment "Pace. Quicker (because I was good?)" Original statement was "I would be finished far ahead of everyone in my class" (ID69).

In (f) the miscellaneous code proved useful for collecting statements that were hard to categorise or would require a new code to be classified. Of the 36 statements coded, 28 were reclassified leaving only 8 statements remaining as miscellaneous.

## Discussion

This paper outlined a hybrid inductive and deductive methodology to facilitate a thematic analysis which incorporated the knowledge gained from previous work on mathematical identity in Ireland while also continuing to be grounded in the new data from this study. We built on the previous grounded theory research by MIST/MINT while acknowledging that we do not yet have a fully validated and reliable process for accessing mathematical identity. The categories developed by MIST/MINT were particularly helpful to determine whether a code might be present in a statement. Adopting a finer, detailed coding approach at stage 4 with many steps acknowledges that students' narratives are a link or window to their identities rather than being their putative 'actual' identities. The ever-changing nature of identity necessitated a semantic approach where one does not look "beyond what a participant has written" when coding. The interpretative stages happen during analysis after coding has taken place. This is in line with the advice of Braun and Clarke (2006, p. 98) but contrary to that of Boyatzis (1998). All steps of coding proved useful for combating discounting of evidence in uncoded text (Crabtree & Miller, 1999, p. 171) particularly coding 'pieces of interest' and using keywords. Using a miscellaneous code represented 53 of the 116 (or 46% of) code changes made and thus was the most effective way to ensure that meaningful responses did not go undetected. The small sample size of 32 facilitated this multi-step coding.

We expect this methodology to advance the drive toward an effective process for accessing students' mathematical identities. We see this approach as providing insights for students to improve their learning experiences and for educators to ease the transition to higher education for such students.

# Students' Engagement in Inquiry-based Learning: Cognition, Behavior and Affect

Styliani K. Kourti

University of Athens, Department of Mathematics, Athens, Greece; [stellakour@gmail.com](mailto:stellakour@gmail.com)

*The present study focuses on the constructs of students' engagement in Inquiry-based learning (IBL). We analyzed two mathematics classrooms, using videos and interviews with the two teachers. After recognizing the IBL phases, a synthesis of Kong, Wong and Lam (2003) and Liem and Martin (2012) models was made in order to determine each student's engagement, in the framework of the IBL. Then the constructs of three students' engagement were also studied in relation to the phases of IBL, trying to identify the type of engagement that prevails at each phase of IBL. According to the results 35 out of 47 students studied were highly engaged. All high achieving students were highly engaged, having all three constructs of engagement increased. Low achieving students with high engagement presented intense behavioral and affective engagement. There were also low achieving students that presented low engagement during IBL.*

*Keywords: Inquiry-based learning, engagement, affect, workplace.*

## Introduction

Over the last few decades, serious concerns have been expressed about the quality of teaching and learning in mathematics and science and the need for improvements in order to meet the increasing needs of society (Artigue & Blomhøj, 2013). Inquiry based learning (IBL) approaches are promoted in research and developmental programs in mathematics and science (Pedaste et al., 2015). Several research projects, such as, the European, Mascil project (<https://mascil-project.ph-freiburg.de/>), seek to diffuse IBL in science and mathematics teaching in primary and secondary education. Much of current IBL's research focuses on cognitive issues, communication, mathematical competence, tools and resources for planning or implementing inquiry, professional development and collaboration-based learning (Dreyøe, Larsen, Hjelmberg, Michelsen, & Misfeldt, 2018), and less on affect during IBL.

In the educational context, students' motivation and engagement play an important role in their achievement and their interest in school (Liem & Martin, 2012). Students' disengagement is a contemporary issue of mathematics education, as it may affect long-term development of our communities (Attard, 2012). Although many IBL projects showed some positive benefits for students' learning, engagement's complex and multifaceted construct may be the reason why little research has been done to study engagement in IBL context.

Therefore, we consider it necessary to study IBL in relation to students' cognition and affect, arguing that the use of IBL approaches can contribute to the increase of their engagement. This study focuses on the constructs of students' engagement while IBL approaches are adopted in mathematics teaching. The research questions are: Can the implementation of IBL affect students' engagement? Which constructs of students' engagement (cognitive, behavioral, and affective) appear and intensify in the IBL phases?

## Theoretical Framework

Inquiry-based learning, according to Pedaste et al.'s (2013), is a process in which learners construct knowledge by discovering new causal relations, formulating hypotheses and testing them through experiments, and making observations. An important characterization of IBL is the development of an inquiry cycle (the phases of IBL with their sub-phases, and their interactions), a concept that has various definitions in the research literature. Pedaste et al.'s (2013), bibliographic review and synthesis of 60 articles identified the exploratory cycle that includes the phases of orientation, conceptualization (questioning and hypothesis generation sub-phases), investigation (exploration, experimentation and data interpretation sub-phases), conclusion and discussion (communication and reflection sub-phases), while almost all phases are related to each other.

Motivation is a central concept of affect research, and it can manifest itself in knowledge, emotion and/or behavior (Hannula, Evans, Philippou & Zan, 2004). The structures of engagement and motivation are often used together and are very closely linked. Motivation is defined as people's energy and boost for learning, effective work and achievement of their full potential, while engagement is defined as behaviors that align with this energy and lead (Liem & Martin, 2012), but engagement is more complex than observed behaviors. Kong, Wong and Lam (2003) developed an instrument for detecting students' engagement in the mathematics classroom, which operates in three levels: cognitive, behavioral and affective engagement. Cognitive engagement involves the idea of recognition of the value of learning and the willingness to go beyond the minimum requirements, while behavioral engagement encompasses the idea of active participation and involvement in academic and social activities (Attard, 2012). Affective engagement implies a sense of belonging and acceptance of the goals of schooling, and is related to the notions of self-efficacy, expectation, interest, perceived control, and autonomy (Kong et al., 2003). Several studies have found that the three constructs of students' engagement do not work individually but support and complement each other in a cooperative way. Also, Liem and Martin (2012) developed the Motivation and Engagement Wheel, which is a multidimensional framework representing salient cognition and behavior pertinent to motivation and engagement, and offers a discrimination tool for cognitive and behavioral elements of engagement (see Liem & Martin, 2012, pp. 4-7).

## Methodology

### The context of the study and the process of data collection

The present study is a case study of two mathematics classrooms, conducted in Athens, Greece. The data used were videotaped lessons and semi-structured interviews with both teachers. The lessons were designed within the context of a European research project, Mascil ([www.mascil-project.eu](http://www.mascil-project.eu)), that aims to support teachers in using IBL approaches into their teachings, and making connections to workplace (activities that involve authentic problems, and can be more or less similar to activities actually carried out by workers in the workplace with more or less use of authentic tools/artefacts).

A grade 10 class, (27 students, boys and girls, mixed cognitive dynamics, 15-16 years old), and a grade 11 class (21 students, boys and girls of mixed cognitive dynamics, 16-17 years old) were studied. Two videotaped lessons were analyzed in which the teachers used the "Drug concertation" task, from Mascil's platform, where students partly adopt the role of pharmacologist in finding out

how drugs work in the body, using mathematical models instead of experimenting in a laboratory (<http://www.fisme.science.uu.nl/toepassing/22038/>). The grade 10 classroom was divided into seven groups of students, while the grade 11 classroom into five groups. Each group's students were chosen by the teachers, so that groups of mixed dynamics were created.

Both interviews with the teachers lasted about one hour. Teachers responded to questions about each student's performance and participation before and during IBL. Episodes related to students' engagement from the videotaped lessons were selected by the researcher and discussed with the teachers, and questions related to the IBL process were asked in relation to the selected episodes.

### Data analysis

The groups formed in the classroom were the groups of our analysis. In order to facilitate this process, based on individualized students' data drawn from the interviews with the teachers, students were grouped into two groups. The group of high achievers includes students with a great interest in mathematics, a high cognitive mathematical level, active participation in the mathematics discourse in the classroom. The group of low achievers includes students with moderate, low or no interest in mathematics, medium or low cognitive level, low or no participation in the mathematics discourse in the classroom. One student out of 48 couldn't be studied because of inadequate data.

In order to distinguish IBL phases in each lesson, each teaching was studied at classroom level, using the videos and teachers' interviews, trying to identify the points of change of the phases, and their localization, based mainly on the cognitive processes of the students. Then, after determining the relationships between the phases and the sub-phases of IBL, the IBL framework for each of the teachings was formed, according to the pedagogical learning framework of Pedaste, et al. (2015).

A synthesis of Kong et al.'s (2003) and Liem and Martin's (2012) models was made, in order to determine students' engagement, in IBL's framework. Kong et al.'s (2003) model was used for the engagement constructs (cognitive, behavioral, and affective) enriching it with the sub-constructs of the Liem and Martin's (2012) model. The videos were observed and transcribed. Based on this scheme, the data of each classroom's video was coded student by student. Through this process, the coding scheme used for the analysis of each student's engagement is presented below in Table 1.

	Engagement	Indicators
Cognitive	Connecting with previous knowledge, Dependence on the teacher, Trying Examples, Comprehend question, Justification of arguments, Explanation to the other members of the group, Independent work, Dependent work, Memorization, Abstraction (limit notion intuitively), Superficial strategies, Passive	Questions, Completing peers' phrases, Exchange of ideas, Give directions explanations and information, Justification of an argument, Answer teacher's questions, Give information, Explain processes and justify, Question the teacher, Gestures
Behavioral	Attention, Persistence, Thoroughness, Participation, All over the task, Partial Participation, Surface participation	Body movements, Face expressions, Verbal expressions, Interaction with peers (verbal, body), Gestures

Affective	Anxiety, Uncertainty, Interest, Enthusiasm, Joy, Disruption, Boredom, Curiosity, Uncertain control, Failure avoidance, Anger, Goal achievement	Face expressions, Verbal expressions, Body Stance, Gestures
-----------	------------------------------------------------------------------------------------------------------------------------------------------------	-------------------------------------------------------------

**Table 1: The constructs of student engagement and their indicators**

Recognizing the constructs of students' engagement was a complex methodological process, as the engagement is a multidimensional concept also related to the internal affective structures of each individual. An example of our analysis is illustrated below, concerning the engagement of a high achiever, in mathematics, student:

Listening to the explanations of the other members of the group (behavioral- attention), he is crouched over his notebook (behavioral- all over the task), hitting his pencil on the desk and overcrowding his eyebrows (affective- anxiety and uncertainty). Using footnotes in a tooltip over the paper to help organize the presentation of the solution (behavioral- thoroughness). At the same time he says: "no, we do not have to do that because our teacher will not like it ... though it seems to me right (cognitive- dependence on the teacher and dependent work) ... I do not know what to do [puff and blow] (affective-uncertain control and anxiety) ... let's ask him to be sure he (referring to the teacher) knows better (cognitive- dependence on teacher, affective- failure avoidance)".

Then each student's engagement was evaluated as high or low based on the three constructs of engagement he had presented. Each of the three constructs was equally accounted for, for the above evaluation. High is recognized as the engagement of a student who has an intensified engagement in at least two of its constructs (cognitive, behavioral and affective engagement).

The constructs of student engagement were also studied in relation to the IBL phases, in three cases of students, trying to identify the type of engagement that prevails at each IBL phase. The first student (boy, grade 11) was a high achiever and presented high engagement, the second student (girl, grade 10) was a low achiever and presented high engagement while the third (girl, grade 10) was also a low achiever but presented low engagement. The students 1, 2 and 3 were typical representatives of their achievement groups and an overall picture of students' engagement in the IBL phases could be formed.

## Results

The results of this research showed that both classrooms during IBL presented all IBL phases and sub-phases, except experimentation (investigation phase- no experiment was required to test the hypotheses), as well as reflection (discussion phase- limited time spent on this phase).

In grade 10, one of the twenty-seven students could not be analyzed because of inadequate data. Seven of twenty-six students presented low engagement, while the remaining nineteen presented high engagement. Seven of the highly engaged students were low achievers, while the other twelve were high achievers. Regarding the highly engaged, low achievers group, all of them had intense affective and behavioral engagement, but six of them had low cognitive engagement, as they were only using

superficial strategies. For the twelve highly engaged, high achievers, all three constructs, particularly cognitive, were intensified.

	<b>Total</b>	<b>Highly Engaged</b>	<b>Cognitive engagement</b>	<b>Behavioral engagement</b>	<b>Affective engagement</b>
<b>Low Achievers</b>	24	12	Limited	Intensified	Intensified
<b>High Achievers</b>	23	23	Highly Intensified	Intensified	Intensified

**Table 2: Overall results of students' engagement**

In grade 11, fifteen out of the twenty-one students presented high engagement while the remaining six students presented low engagement. Five of the highly engaged students were low achievers, while the other ten were high achievers. The highly engaged, low achievers had intensified affective and behavioral engagement while the cognitive engagement of three of them was low, since they were only using superficial strategies. All high achievers were highly engaged, having all three engagement constructs intensified, especially their cognitive one. Table 2 presents aggregated results of students' engagement.

### **The constructs of engagement in the phases of IBL: Three cases of students**

Then, an attempt was made to identify the intensified constructs of students' engagement in each IBL phase, of three representative cases of students. The findings are summarized in Table 3 (where CE, BE and AE are cognitive, behavioral and affective engagement respectively, and with bold are the intensified engagement constructs of each phase).

Student 1 was a highly engaged, high achiever. He was highly affective engaged in orientation phase, demonstrating interest and enthusiasm for the activity. In conceptualization phase, his behavioral engagement was intense, as he was constantly all over the activity, paying attention and showing persistence. Affectively, in the same phase, he was very enthusiastic about both the context and the solution process of the task. In investigation phase, all three constructs of his engagement were intensified. Of particular interest was the development of his cognitive engagement as he addressed questions of understanding both to the teacher and to the other members of his group, he used trying examples, connected the old knowledge with the new one, and almost at the beginning of the investigation phase he realized, through the diagram, that the function tended to be limited in a number, and later he explained his thought to both the professor and the rest of the group, being very joyful about it. In conclusion phase, his cognitive engagement was intense as he tried to explain his thoughts to the rest of the group using arguments. Finally, in discussion phase, all constructs of his engagement were intensified, as he revived the entire previous inquiry process. While he was communicating his group's results to the rest of the class, he was very enthusiastic about their solution.

Student 2 was a highly engaged, low achiever. She, in the orientation phase, did not seem to have any interest in the activity, and she also presented signs of boredom. In conceptualization phase, her curiosity was triggered, so she began to ask questions of understanding the activity, while at the same time she was paying attention. In investigation phase and in conclusion phase, all three constructs of

her engagement were much intensified, and were kept unabated throughout these phases. Affectively, she was very interested and curious in getting involved with the task. Feeling uncertain control, she tried to explain to the other members of her group her understanding of the solution given. Finally, in the discussion phase, during which the group presented its results to the rest of the class, the student's 2 engagement was limited, while only her behavioral engagement was intensified, leaving some other members of her group to present the cognitive part.

	<b>Student 1</b> <b>High Engagement</b>	<b>Student 2</b> <b>High Engagement</b>	<b>Student 3</b> <b>Low Engagement</b>
<b>Orientation</b>	CE: Comprehend questions BE: All over the task AE: Enthusiasm, Interest	CE: None BE: Attention AE: Boredom	CE: None BE: Partial Participation AE: Boredom
<b>Conceptualization</b>	CE: Comprehend questions, Trying examples BE: All over the task, attention, Persistence AE: enthusiasm, interest	CE: Comprehend questions BE: Attention AE: Curiosity, Interest	CE: Passive BE: Partial participation, Attention AE: Curiosity
<b>Investigation</b>	CE: Connecting with previous knowledge, Trying Examples, Comprehend question, Justification of arguments, Explanation to the other members of the group, Abstraction (limit notion intuitively) BE: All over the task, attention, Persistence, Participation AE: Interest, joy, uncertain control	CE: Comprehend questions, Trying examples, Connecting with previous knowledge BE: Attention, Thoroughness, Participation AE: interest, curiosity, uncertain control	CE: Passive BE: Partial participation, Attention AE: Curiosity
<b>Conclusion</b>	CE: Connecting with previous knowledge, Explanation to the other members of the group, Abstraction BE: Attention, Participation AE: Interest, joy	CE: Trying Examples, Explanation to the other members of the group BE: Attention, Participation, Thoroughness AE: Interest, Curiosity	CE: Passive BE: Partial participation AE: Interest, Boredom

<b>Discussion</b>	<b>CE:</b> Connecting with previous knowledge, Explanation to the classroom, Abstraction	<b>CE:</b> Connecting with previous knowledge	<b>CE:</b> Passive
	<b>BE:</b> Attention, Persistence, Participation	<b>BE:</b> Attention, Thoroughness	<b>BE:</b> Attention
	<b>AE:</b> Interest, enthusiasm, joy	<b>AE:</b> Interest	<b>AE:</b> Disruption, Boredom

**Table 3: The constructs of student engagement in the stages of IBL**

Student 3 was a low achiever who presented overall low engagement, especially in the phases of orientation, conclusion and discussion. In conceptualization phase she showed interest and thus her affective engagement was intensified, while in investigation phase her behavioral engagement was intensified as she showed some attention and partial participation. In all phases she was cognitively passive, like the other students of this case. Affectively, the students of this case seemed to be bored during the whole activity, except from conceptualization phase, during which some of them showed a bit of interest, or curiosity, mainly for the context of the activity.

## Discussion

According to the results 35 out of 47 students were highly engaged. This may be due to the possibilities offered by Inquiry-based learning and teaching, as according to Artigue and Blomhøj (2013), it becomes a potent tool in personal and collective response efforts of an important question, making these experiences not only unpublished but inspired and structural for the whole educational project.

The students of case 1 were cognitively highly engaged in the investigation, conclusion and discussion phases. This is probably due to the fact that IBL, on average, increases conceptual understanding in science, mathematics, engineering and technology courses (Freeman et al., 2014, as cited in Capaldi, 2015), while traditional teaching can lead to low levels of conceptual comprehension (Epstein, 2013, as cited in Capaldi, 2015). The students of case 2 were all highly engaged, especially in the investigation and the discussion phase. This may be due to the fact that these two IBL phases are relying on group-work and collaboration provides support for tackling difficult problems or concepts (Capaldi, 2015), which encourages students to be active participants in the construction of their knowledge. Yet several students in this group showed low cognitive engagement in the entire IBL process. This might be due their previous cognitive deficiencies, or to their dependence on their group's highly achieving students, in a cognitive and affective way.

Highly engaged students, of both cases 1 and 2, showed intense behavioral engagement and positive affective engagement. This may be due to the authenticity of the workplace activity, allowing them to realize the usefulness of their school mathematics education and redefining their motives. Students' positive affective engagement may be due to the dissociation of the IBL activity from their grade retention. Grade retention often leads to maladaptive behavior, impeding cognition (Liem & Martin, 2012), causing negative emotions (for example anxiety) about mathematics education. All three

constructs of engagement are interrelated (Kong et al., 2003), thus negative affective engagement relates to negative behavioral and cognitive outcomes, and vice versa.

But the results from students of case 3 showed that despite the opportunities offered by IBL to increase students' engagement, there are students who are not motivated by them, without this, however, rendering them ineffective, since the number of these students is small compared to our rest sample. These students, according to their teachers, have no interest for the lesson, do not participate and most of them are mathematically weak. This is probably due to affective variables, which can be seen as indicative of learning outcomes or as predictive of future success (Hannula et al., 2004) or failure. At this point, further research into the subject's discipline is necessary.

One of the limitations of this study is that its inferences were mostly drawn from (replicated) observations, and in a subsequent phase, it would be good to combine with personalized interviews with the students to deepen more the analysis. Finally, some critical questions for future research arise: Can the more frequent use of IBL approaches alter the engagement of weak learners? If so, which constructs of engagement could be affected and in what way the IBL cycle may change?

# Investigating emotional intensity in mathematics classrooms: an enhanced methodology or affective gimmickry?

Elizabeth Lake

UCL Institute of Education, UK; [elizabeth.lake@ucl.ac.uk](mailto:elizabeth.lake@ucl.ac.uk)

*One known issue when working with emotions in context is the challenge of observing what are often transitory, fluid, and unconscious emotions, that vary in intensity and valency, and can change depending on when or who is asking. This paper reports on how one physiological measure, a simple galvanic skin response (GSR) sensor, which has become possible to use in class due to technological advances, can be used in conjunction with other methods such as observation and stimulated recall interview and can give insight into variations of a mathematics teacher's emotional intensity as they interact with students. The addition of physiological data to a common form of methodology provided useful prompts for teacher reflection and hence has potential for supporting development and is potentially a powerful addition to more common methodologies.*

*Keywords: Emotions, Intensity, Teachers, Physiological data, Mathematics.*

## Introduction

This paper discusses a method for examining emotional intensity in mathematics lessons, addressing this challenge through the incorporation of physiological data in addition to more common methods. Pekrun (2018) lists five ways to assess emotions; self-report, implicit assessment, neuro-imaging, behavioural observation (e.g. facial or postural expression) of emotionality (De Simone, 2015), and peripheral physiological analysis. In this paper, the focus is on incorporating the use of Galvanic Skin Response (GSR) to the study, a physiological measure applicable to studying intensity of emotions. There are studies of undertaking Mathematical tasks whilst being measured for heart rate and temperature, however measuring GSR is less intrusive than, for example, heart rate.

The wider study originated from a desire to explore how experienced teachers (past the emotional transition of training) use emotions, particularly positive emotions, within the social interactive context of teaching. There is evidence that exposure to positive emotions supports recall (Titsworth, McKenna, Mazer & Quinlan, 2013). Whilst, from a student perspective, Mottet & Beebe (2000) suggest that affect directly determines time spent on a task. Additionally, experiencing a social environment that includes emotions such as enthusiasm (Kunter et al., 2008), is likely to encourage perseverance and engagement. Early in the investigation of affective practices, I realised that little is known about the use, or the degree of intensity of emotional expression, but that emotional intensity and engagement are closely associated.

The data comes from experienced secondary mathematics classroom teachers in the UK. The method is illustrated by two teachers from the same school, Carol and Debbie, both deemed 'good' teachers by the school, in that they both have a strong rapport with students. The full research design incorporated that emotions are transitory, that they depend on context and evocation, and explored what teachers bring to the classroom (through pre-observation interviews), interaction (through videoed and audio-recorded lessons), and how teachers perceived the interaction (through stimulated recall interviews). The method was designed to explore the use of positive emotions when teaching

mathematics and to examine whether teacher affective interpretations match the observer perceptions. Embedding the element of GSR measurement offers an additional means of gauging intensity of emotions. This paper aims to show how a measurement of intensity can be incorporated into contextual emotion research, and to identify advantages of such incorporation.

### **Definitions and the wider context**

Emotion can be conceptualised as energy that boosts cognitive functioning; energy that moves back and forth between individuals and the social. Emphasising the intensity of emotions, Lakoff and Johnson (1999) consider emotion is "...better understood as the tension of excitement level produced by the interaction of brain processes of perception, expectation, memory and so forth" (p. 176). The physical temporality emphasised by this definition is appealing as incorporative of the complexity of emotions. I retain the term emotion for use 'in-the-moment', as identifying the fluid and transitory nature of emotions. The energy definition seems applicable to the study of intensity within the dynamic and complex context of classroom teaching. Especially, as Graham and Taylor (2014) note, "[e]motions, then, can be a filter through which the perceiver may make rapid judgements in situations where there is much ambiguity" (p. 115). It seems reasonable that emotions as a filter would elicit internal intensity and the study was designed to capture such intensity. An experienced teacher often intervenes by instinct, as part of apparently effortless 'expert' teaching, and that the intensity of such an instinctive reaction may be internalised. Yet Kahneman (2011) suggests that changing a task, especially rapidly, is effortful. At such points, a teacher might increase their internal engagement, and hence an internal indicator such as skin conductance would show change, as emotional intensity increases. Barsade (2002) confirms that stronger emotions are more effective in communicating emotion, perhaps even with negative valence, as higher energy draws more attention.

### **The surge of physiological data in social sciences and education**

Technologies that support the use of physiological data are becoming more accessible and portable, yet the use of GSR in active contexts remains sparse, usually taking place as study of individuals under static laboratory conditions. For example, within biological psychology, the use of skin conductance is common, with studies ranging from ADHD in boys to antisocial and violent behaviour, whilst many studies involve children where self-reporting is potentially less reliable. However, the application is now wider than sciences. For example, Oxley et al. (2008) suggest that political views have a biological basis. The physiological measures used include measuring change in skin conductance whilst participants were exposed to threatening or non-threatening images. Intriguingly, they found that, for participants with strong political views, lower physical sensitivities correlated with being more likely to support foreign aid, liberal immigration policies, pacifism, and gun control. Skin conductance is also used within risk analysis research. For example, when given a gambling card game task, it appears that, for successful performers, skin conductance levels (SCL) increase before selection of bad decks i.e. a risky choice (Crone, Somsen, Van Beek & Van Der Molen, 2004) which may suggest an internality associated with expertise. Such internality may also apply to experienced teachers who are likely to be skilled at concealing their emotions in class.

Outside the laboratory, Doberenz, Roth, Wollburg, Maslowski & Kim (2011) recorded the GSR of people over a 24-hour period and suggest the technology has become feasible for use outside the lab

with some concerns, such as time delay and interpreting rapid response changes. The context of a mathematics classroom bears little similarity to experiments conducted in a lab, a point that has led to studies on the real-world applications of physiological data, including in education. For example, Koren (2016) developed a device to use with young children in school “to take measurements in children's most natural environment and where authentic behaviors are exhibited” (p. 14). Teachers are significant in forming emotional climates and deciding pedagogical approaches. In a university study about learning geography, student engagement during various pedagogical approaches, was measured using skin sensors on a subset of student participants (McNeal, Spry, Ritayan & Tipton, 2014). Unsurprisingly, they found movies and class dialogues to be more engaging than lectures.

### **The GSR version used**

GSR measures small changes in skin humidity as one indicator of either stress or excitement in the body; an approximation to emotional intensity. The eSense ESensor® (Mindfield Biosystems Ltd, 2013), a simple affordable portable device which attaches to a mobile phone and according to the website, has been previously been used in studies on excitement, anxiety & stress. The sensor records bodily response, either positive or negative, and quickly produces data which is easily converted into an intensity graph. For practical purposes, despite differences in skin response activity being greatest on the palms or soles of the feet, and fingertip measurement (distal phalanges) not possible (a teacher needs to use their hands to write or gesture), researchers recommended using the intermediate phalanges on the first and second fingers of the non-dominant (usually left) hand (e.g. Crone et al., 2004), so the recording is less prone to interruption by loosening of the sensor fastenings or similar.

Whilst observing, I noted intensity points from the teacher, thus using the device to corroborate what I, as observer, experienced and felt. Researchers suggest there is delay between experiencing intensity and recording by the sensor of up to 10 seconds (Oxley et al., 2008) although other researchers suggest a shorter time. Using video recordings surrounding an episode of interest (the 2/3 minutes around the peak value) is crucial to provide corroborative data and raises the importance of subsequent teacher interpretation of the data, as only the teacher can suggest why or what stimulated any GSR change. I incorporated stimulated recall into my method as the final dimension of a holistic and temporal (before, during and after) design; forming a methodology based around case studies using interviews, observation and stimulated recall discussion. The post-observation discussions were designed to enable each teacher to talk about their thoughts and emotions during the videoed lesson, using the clips of their teaching as a prompt with discussion centred on an extract(s) of video. Only at the end of the interview sharing the resulting GSR graph and discussing interpretation of the graphical results.

### **The study's use of GSR sensor data: Carol and Debbie**

By the time I was observing classes in school, much of the crucial (and intense) norm setting that takes place at the start of a new academic year was in place, so I observed normal daily practice rather than norm establishment. Participants were all teachers qualified (QTS) to teach mathematics at secondary school level with a least 3 years' experience, thus limiting the influence of extremes of emotions associated with novice change processes.

The teachers wore the device in earlier sessions, without recording, until they felt comfortable, as wearing an ESensor device whilst teaching may unintentionally affect classroom interaction. I

informally practiced with the device with lecturers in university seminars, and within a few minutes, wearers behave as normal and all the participants reported forgetting about the recording and, although aware of the device, there is no apparent change in their observable behaviour. Software for video editing (Microsoft moviemaker) was used to extract clips to share with teachers. The two episodes presented here were based on highest intensity readings. Observation notes enabled me to use the device to corroborate what I, as an observer, experienced. Occasionally, the ESensor device failed to work. Although I provided a belt pouch for phone and voice recorder, there were still trailing wires, which were occasionally pulled out. In order to conduct the post-observation discussions as soon after lessons as possible, preparing for discussion required rapid examination of the video, and the ESensor graphs proved particularly useful in the process of episode selection. The excitement and interest engendered by the use of the device was notable in all cases; it has novelty, even if it is occasionally unreliable. Participants were aware of, and were happy with, the risk that GSR measuring may reveal more than a teacher wishes to share, as what triggers emotional reactions can be deeply personal and is often hidden, even from self. Combined, the data of interview, video and ESensor recordings and post observation discussion tell one possible story of each teacher and their affective professional life. The physiological measure, through the use of the ESensor, results in numerical data, that, when graphed, provides a visual insight into a lesson to share with each teacher. I next present illustrations of the use of the ESensor with two participants, Carol and Debbie, showing one of the videoed lessons in each case.

## CAROL

**Figure 1: Graph of lesson (Carol)**

**Figure 2: Teacher C (Carol) ESensor distribution**

In the episode selected by the maximum reading in microSiemens ( $\mu\text{S}$ ) over time (indicated by the box in Figure 1), Carol exhibits characteristics of mild frustration or puzzlement in a predominantly calm yet positive lesson. I do not think I would have noted this episode based on observation alone. In the episode Carol is modelling a careful assessment of the situation before acting, as well as patience and thoughtfulness when doing mathematics. She encouraged explanation from students with her head on one side, with expectant body posture and interested face (Figure 3). Finally, we have emotional uncertainty or doubt. This is visually expressed as biting her lip and putting her head on one side and then the other, and articulated later as apprehension, "... because I knew they should be able to do it [Draw the graph], but they weren't giving me anything back". In post observation discussion, she assigns this doubt to either lack of understanding or to the group dynamic. Her behavioural response, both observed and subsequently explained, is to shift from instructional mode

to conversational level. Accordingly, she sits down with the group. She explains this action as, “...trying to get down on their level and having more of a conversation”.

**Figure 3: Episode images (Carol)**

One student in the group (shown to her left) is unknown to her, and she later expresses concern that she does not have a strong relationship with him. She thought that this unknown factor could potentially shift her out of her comfort zone and may account for the higher ESensor measurement. There were multiple possible reasons discussed in post-observation interview.

## DEBBIE

The box in Figure 4 indicates the video clip used with Debbie. The higher values at the end occurred after the end of the lesson. Given the active nature of Debbie whilst teaching, with rapid movements and many emotional expressions, I would have predicted more variation in the graph (e.g. Figure 4), which are relatively consistent, although with a higher median value than for Carol (Figure 2, Figure 5) The base values for each teacher differ. This perhaps draws attention to the internal and external nature of emotions. For example, a teacher who is overtly emotional whilst teaching may have reduced internal affect or vice versa. Without the use of a physiological measure this potentially important difference is invisible.

**Figure 4: Graph of lesson (Debbie)**

**Figure 5: Teacher D (Debbie) ESensor distribution**

In the selected episode, identified by uniting observation and ESensor, we see Debbie multitasking, moving rapidly from one group of students to another, answering and asking questions, a repeated pattern within the observed lessons. Even her discourse changes attention rapidly.

Student: Miss, we've done it!

Debbie: Wooo! [Excited voice] Can you please put it in your um...Right, you are going to take that and you're going to do that now...Put it in your paperclip and come and see me... so that's Kim and Lee, ok Lee. Right, take one of those, you are going to work on that between you...and stick it in... [To another student] Ooh...swearing? [Louder] No!

My impression from this is that modelling enjoying doing mathematics is important to her. For example, in the selected episode she uses playful language and body movements. She waves her arms

to show an aeroplane flight path to two students who were engaged in an extension task on angles of elevation and depression. One of the considerations for ESensor use was movement, but comparing readings across the lesson, similar value appears without being associated with movement, a point verified by other studies (e.g. Koren, 2016).

Both teachers commented on their graphs in general at the end of the stimulated recall interview. Carol, whose graph is more variable, yet presents as mainly unemotional in the observed lessons, says of the video before seeing her graph, “I was shocked how calm I looked, I don’t feel like I’m that calm... perhaps I am not conveying it [excitement], because a lot of it is the day to day of it, I’ve done it 20 times, 50 times, 100 times...” whereas Debbie, who is constantly active in her teaching, comments afterwards, “that’s intriguing, maybe I look like I’m a bit mental but I’m actually pretty calm.”

## Discussion

The teachers were intrigued by emotional intensity research and I suggest the resulting discussions were focused and relevant. The exemplar teachers, despite no intention to compare, offer contrast in terms of visible emotions in the classroom. Debbie is overtly emotional as she teaches and Carol the opposite, yet their ESensor graphs appear to indicate otherwise, suggesting there is more to be learnt from the use of this tool. The use with Carol and Debbie, has challenged a common view that, in order to engage students in learning, there must be some notable teacher expression of positive emotions; that they have to be overtly expressed to be useful. However, this somewhat validates the use of the ESensor, as Carol is still experiencing emotions, albeit hidden, and her comments in interview confirm this. Both Carol and Debbie take pleasure in their classroom teaching, in having strong relationships and effectively communicating the mathematics that students need, as well as care for the student emotional needs (Lake, 2015). In this endeavour, emotions play a subtle, yet central, part within their different classroom practices. I would suggest that the use of the ESensor to hone in on their emotions in-the-moment, has strengthened attending to this aspect of the study.

A valuable contribution of the ESensor use is as director for the selection of episodes. The tool enabled a quick turnaround with creating a video extract to share with teachers (in all cases the next working day). Usually selection of stimulated video recall relies on repeated watching of lengthy video to select a suitable episode, and when selected inherently has bias through observer selection and interpretation. Some (although not all) bias is reduced by using the ESensor graph to select episodes. There are limitations to acknowledge; GSR offers a rough approximation of intensity, whilst the rapidity of change in emotions means interpreting the graphs can be challenging. This is one reason for attending to the teacher interpretation, but even then, there are many reasons for intensity at any point, some of which may not be shared with an interviewer. The most significant limitation is the multiple possible interpretations and hence the unreliability, unless intense emotions are involved. However, overall, a strength is in facilitating a more focussed discussion in many cases, so more perhaps than affective gimmickry. A further limitation to acknowledge is that some lessons do not have notable indications of intense emotions. In these cases, the choice made was to use the maximum value, and to share the episode around this value with teachers. In some cases, the choice was little above the median for the lesson.

Three main implications arise from the use of the ESensor. Firstly, that awareness of use of emotions as a precursor to self-development has potential for developing self-regulation. Secondly, the data produced some potentially intriguing patterns for further investigation, albeit based on a small sample. Thirdly, as in both examples used here, the peaks frequently occurred in conjunction with supporting students to understand a specific point. This has implications for where a teacher should use intensity, something the experienced teachers may do instinctively and merits further investigation.

Consciousness of emotions, or even awareness of the activity of teaching is an issue especially pertinent to studying experienced teachers. New teachers are cognitively conscious, although not so effective at noticing wider than singular activity, such as when working one-to-one (Mason, 2002). Whilst experienced teachers often find it hard to articulate what happens when teaching, as only discrepancies are memorable. The use of the ESensor may support examination of engagement in contexts such as training. The second implication is that early indications imply that teachers who might be identified (by their students) as more engaging teachers are repositioning more frequently, which is associated with being responsive to students, but which is potentially more effortful. The ESensor may have a future role in identifying such patterns. One might speculate that it is this characteristic of engagement that the ESensor is helpful in identifying for early career teachers.

In the two examples, peaks occurred in conjunction with supporting students to understand a specific point. In Carol's case, how to create an appropriate graph, and for Debbie, what it means to visualise an elevation whilst managing other tasks simultaneously. One might suppose that both episodes require intensity to communicate the ideas, and as such is effortful, as highlighted by the ESensor. Teachers direct their communicative effort and intensity towards points of most impact on learning, meaning to change pace, to interrupt as in performance, or to restore emotional balance. Yet teachers cannot continually sustain high intensity, so there is much to be learnt about deliberate and instinctive placing of intensity. The idea of managing emotions of others through meta-awareness of intensity is not new. Mason (1989) talks of meta-awareness in terms of 'Knowing-to', which is, "...the kind of knowledge which enables people to act freshly and creatively" (p245). Amongst the participants, I observed apparently unconscious and almost instinctively managed tailoring of intensity. The use of the ESensor was aimed at partially addressing this methodological challenge, as assessing the degree of emotional regulation is important to interpreting emotions of classroom teachers.

To conclude, there are indications that the incorporation of physiological data is a powerful addition to common methodology for examining emotions in-the-moment. The use and sharing of each resultant graph, by acting as a focus for discussion, has facilitated discussion between myself and the participant teacher, and enabled each teacher to explore their emotions during the selected episode, and to articulate these through the medium of the ESensor. The use of the ESensor seems to have focused attention on what may be critical moments in a lesson. The potential is rich, the study is encouraging of the potential for GSR use in future research, both to validate the use of a sensor as having value within affect research and as a means to address the concern of affect researchers around the unavailability of emotions and hence one known limitation in any study of emotions. The ESensor usefully guided the selection of extracts from a lesson, focussing attention on indications of intensity, in addition to observation notes and my own response to the teacher.

# **Pupils' perception of their understanding in mathematics and its connection to private supplementary tutoring**

Gabriela Novotná

Faculty of Education, Charles University, Czech Republic; gabriela.novotna@jeida.cz

*Very little research has been done in the area of pupils' perception of their understanding and in tutoring in the Czech Republic, so this paper describes one of prime attempts to find any connections between them. In a sample of 142 lower secondary pupils, distinctive attitudes were sought towards their desired understanding in mathematics and towards their attendance on tutoring lessons in mathematics. The results show there might not be much connection between these two areas, therefore, reasons are discussed and questions for further research are stated.*

*Keywords: Mathematics, understanding, knowledge, private supplementary tutoring.*

## **Introduction**

It may seem self-evident that pupils would like to understand mathematics. This claim is supported by various research (e.g. Ali, Reid, 2012), nevertheless, researchers agree on the fact that when understanding is too difficult, pupils tend to memorize concepts by rote (Ali, Reid, 2012; Skemp, 1978).

The quality of pupils' understanding is often investigated, however, not much attention is paid to pupils' notion of their own understanding and its quality. Attitudes towards one's own understanding could also influence whether someone attends private supplementary tutoring (PST) lessons, therefore, a connection between pupil's attitudes towards their understanding and towards tutoring is analyzed in this paper.

The incentive for writing this article was a small-scale study conducted by the author, where 19 pupils of private supplementary tutoring were given a short questionnaire concentrating on their attitudes towards their own understanding and quality of their knowledge in mathematics (Novotná, 2018a). The study showed that pupils have differing comprehensions of what it means to "understand mathematics". Thus, a follow-up study was realized where a similar selection of pupils was asked a question: "Try to put into words what it means for you that you understand something in mathematics" (Novotná, 2018b). Analogously, two kinds of understanding were exposed, the deep and the surface one (see section Theoretical background).

As a consequence, a larger and more detailed study has been done, which is presented in this paper. Do pupils mind when they do not understand something in mathematics properly? Do they seek tutoring lessons to help their understanding? Or is there any connection between understanding in mathematics and attending private supplementary tutoring lessons?

## Theoretical background

### Understanding in mathematics

Understanding is based on images or imagined feelings, situations, etc., or conceptual representations (Sierpiska, 1994). The level of understanding also influences the way we perceive and process new information.

Skemp distinguishes two kinds of understanding. *Relational understanding* is seen as “knowing both what to do and why”, while the *instrumental understanding* is characterised as “rules without reason”, because a pupil is able to formulate a rule, uses it in a standard situation, but does not understand why it works (Skemp, 1978, p. 9). None of the types of understanding should be refused, according to the author, nevertheless the relational understanding seems to be more suitable for mathematics due to its complexity, because it tends to be easier to remember, more permanent, adapts easily to new tasks, etc. (Skemp, 1978).

Types of understanding are also captured by Hiebert and Lefevre’s notions of *procedural* and *conceptual knowledge*. Conceptual knowledge is defined as “knowledge that is rich in relationships” and can be imagined as a web of knowledge where “the linking relationships are as prominent as the discrete pieces of information” (Hiebert & Lefevre, 2009, p. 3–6). Procedural knowledge consists of two distinct parts – a formal language or a symbolic representation system, and algorithms and rules for completing a mathematical task. Star supplements the theory saying that both types of knowledge can be unequally deep, complex, or shallow or restricted, so we should distinguish different levels of procedural and conceptual knowledge, too (Star, 2005). For purposes of this paper,<sup>1</sup> the types of understanding like relational and conceptual are referred to as a *deep understanding*, types of understanding as instrumental and procedural are labelled as a *surface understanding*<sup>2</sup>.

### Private supplementary tutoring

PST is defined in this paper as tutoring in a school subject (e.g. Mathematics, or English), which is taught in addition to mainstream schooling. This definition of private tutoring includes private tutoring lessons and preparatory courses (e.g. for entrance exams). The definition is inspired by Bray and Silova (2006, p. 29). However, they take into account only tutoring for a financial gain. Very little research on PST has been conducted in the Czech Republic. The only quantitative study was done by Šťastný (2016) who, within his doctoral thesis, compared his data with international surveys and analyzed the reasons of similarities and differences. The author collected questionnaire data from 1 265 students in the last year of higher secondary education in two regions of the Czech Republic, interviewed 22 tutors and analyzed tutoring offers on a specific tutoring website. He found out that, after foreign languages, Mathematics is the second most common subject for tutoring (Šťastný, 2016).

---

<sup>1</sup> There are other attempts to capture types of understanding, for example, in the Czech context, Hejny’s distinction between mechanical and non-mechanical knowledge is elaborated.

<sup>2</sup> Among the authors, there, of course, are minor differences in their conception of deep and surface understanding. However, for the purpose of this paper, these are not of a high importance.

The most common reasons for attending tutoring lessons were labeled “bad marks” and “preparation for a school-leaving exam”.<sup>3</sup>

Authors often point out that in mathematics tutoring it is often procedures and methods which are emphasized (e.g. Bray, 2010; Hohoff, 2002). Pupils are taught to solve tasks only mechanically, without deep understanding, which usually means that it is impossible to further develop their knowledge. The procedures and methods are often soon forgotten.

### **Perception of one's understanding and its implications**

Mathematics is often labelled as one of the least popular and most difficult school subjects (e.g. Hrabal & Pavelková, 2010; Chvál, 2013). According to Chvál (2013), it is very difficult to measure all three components of an attitude (cognitive, affective, and behavioural) quantitatively. Qualitatively, we can pose extensive questions to a respondent or observe their reactions when solving mathematics problems; but mostly, only the cognitive and affective components are measured.

Some research on attitudes towards mathematics has been done: there is a reciprocal relationship between attitudes towards mathematics and achievement in it (Ma, 2012), learners' attitudes are also greatly influenced by school teachers (Ponte et al., 1991), and the social context is an influential factor, too (Hannula et al., 2018). However, as far as we know, the notion of one's understanding or knowledge has not been paid attention to. Some links can be found to self-efficacy, since positive beliefs and higher self-efficacy tend to be correlated with high performance in maths (Hannula et al., 2018).

## **Study**

### **Research questions**

RQ1 –Is there any specific kind of understanding that pupils of selected lower secondary schools seek in mathematics?

RQ2 – Is there any connection between a desired kind of understanding and attendance on PST?

RQ3 – Does the attendance on PST change the notion of one's understanding in any way?

The study was realized in two lower secondary schools in Prague, Czech Republic during the first week of the school year. 149 pupils were given a questionnaire, seven of them were later excluded from further analysis, due to their incomplete and/or contradictory answers and/or their different mother tongue, making 142 respondents in total (see Table 1). The questionnaire was given to the whole class, no selection of pupils was made, all the grades were given the same questionnaire.

---

<sup>3</sup> The reasons for seeking tutoring differ between the majority of European and Asian countries. In Europe, such as in the Czech Republic, pupil's bad marks are the common motivation, whereas in many Asian countries, tutoring lessons are attended by successful pupils, since they want to further broaden their knowledge (Lee, 2013).

	girls	boys	total
6 <sup>th</sup> grade	15	23	38
7 <sup>th</sup> grade	24	23	47
8 <sup>th</sup> grade	14	18	32
9 <sup>th</sup> grade	16	9	25
total	69	73	142

**Table 1: Respondents of the study**

topic	set	items
PST in general		1, 2
PST of M (Mathematics)		3–10
attitudes towards PST of M	C, D	11–13
attitudes towards M at school	B	14
attitudes towards M in general		15
attitudes towards own understanding in M	A	16
about the respondent		17–19

**Table 2: Items in the questionnaire**

The questionnaire consists of the following parts (see Table 2): PST in general, PST of mathematics, attitudes towards PST of mathematics, attitudes towards Mathematics at school, attitudes towards mathematics in general, and attitudes towards one's own understanding in mathematics. The questionnaire was constructed on the basis of available literary sources, mostly the following: Silova, Būdienė and Bray (2006) and Šťastný (2016) – PST in general, PST of mathematics; PISA questionnaire (OECD, 2013) – attitudes towards PST of mathematics, attitudes towards Mathematics at school; Hrabal and Pavelková (2010) – attitudes towards mathematics in general; Code et al. (2016) – attitudes towards own understanding in mathematics; and it was further developed and modified by the author.

Four sets of items are mainly important for this paper<sup>4</sup>: A, B, C & D. The following set of items (set A) explores the type of desired understanding in mathematics. Pupils were asked to label their level of agreement on a 5-point Likert scale to each of the 12 statements (only 10 of them were relevant to the research question and thus are presented here). Agreement to the statements marked as + supports deep understanding, whereas agreement to the statements labelled as – supports surface understanding.

- a) – I am satisfied when I manage to solve a task, even if I don't understand the solution.
- b) – Formulas are only for counting, they don't help to understand mathematical concepts.
- c) + It is important for me to understand how formulas and procedures work.
- d) – It's a waste of time trying to understand how formulas were created.
- e) – When solving a task, I only need to know the formula, not why it works.
- f) – Understanding mathematics means that I remember something well.
- g) – When I forget a formula during a test, there is nothing I can do to come up with it.
- h) – The best way to learn mathematics is to learn sample tasks by heart.
- i) + When I learn something new in mathematics, I always look for connections to something I already know.
- j) – All I need to solve a task is to know the necessary formulas.

There are two similar sets of items (sets B and C), measuring how often concrete situations appear. Set Bis aimed at the actual teaching of mathematics, asking: “How often do these situations happen

<sup>4</sup> The questionnaire was given to the pupils in Czech language and was pilot tested. Only some of the results are discussed in this paper.

in your Mathematics lessons at school?"; whereas set C concentrates on ideal tutoring lessons, hence asking: "How often would you like these situations to happen during a perfect mathematics tutoring". The situations<sup>5</sup> in set B are taken directly from a PISA questionnaire (OECD, 2013), for tutoring the same situations are used, only "a teacher" is exchanged for "a tutor", singular is used instead of plural (pupils), etc. Deep understanding is supported by an agreement to these situations. Four-point scale is used, going from "every lesson" to "never or almost never".

In the set D, the respondents were given four reasons why they either attend, attended or would choose to attend tutoring lessons in mathematics. They were asked to label their level of agreement to each of them on a 5-point Likert scale, and subsequently choose the most and least important reason.

The data from the questionnaires were transcribed and analyzed, using different types of t-tests (see the section Results) and methods of a descriptive statistics (arithmetic mean [AM], standard deviation [SD], etc.) in Excel. It was observed, whether there are differences in the evaluations of girls and boys, between respondents with PST experience and without it, and within individual school grades.

## Results

Almost 46% respondents acknowledged participation in private tutoring lessons in Mathematics (see Table 3), with no bigger difference between girls and boys.

	with PST in M	with PST in M (%)	total
6 <sup>th</sup> grade	13	34.2%	38
7 <sup>th</sup> grade	25	53.2%	47
8 <sup>th</sup> grade	9	28.1%	32
9 <sup>th</sup> grade	18	72.0%	25
total	65	45.8%	142

**Table 3: Pupils attending/attended PST lessons in mathematics**

As the most important reason for PST attendance was usually chosen "I want to understand the subject matter in depth" (AM=1.98, SD=1.17, chosen in 38%), whereas as the least important reason it was "I want to do homework" (AM=3.15; SD=1.44, chosen in 71%). However, the reason which was most agreed to was "I want to practice the subject matter from school" (AM=1.07, SD=1.07). No significant difference was found between pupils with and without PST experience ( $p>0.1$ ).

When we compare the evaluation of items in the sets B (Mathematics at school) and C (ideal tutoring) using a paired sample t-test (i.e. evaluation of sets B and C by the same respondent), two items appear statistically significant: "The teacher (tutor) helps us (me) to learn from mistakes we (I) have made",  $p<0.000^6$ ; and "The teacher (tutor) presents problems for which there is no immediately obvious method of solution",  $p<0.05$ . These two items should therefore create the biggest difference between the Mathematics at school and mathematics tutoring.

However, there are almost no significant differences in the evaluation of the set B and C apart, using an independent sample t-test. Among pupils who acknowledge participation in PST lessons, in the set B there is only one significant item, "The teacher presents problems that require students to apply what they have learned to new contexts",  $p<0.05$ , which was agreed to more by pupils without PST

<sup>5</sup> An example of such a situation is: "The teacher asks questions that make us reflect on the problem", or "The teacher asks us to explain how we have solved the problem".

<sup>6</sup> This item was statistically significant ( $p<0.01$ ) even in smaller samples – girls vs. boys, with vs. without tutoring, school 1 vs. school 2, and in individual grades (with exception of grade 6).

experience. There was no significant difference found, neither between the pupils who acknowledged participation in private tutoring lessons and who did not; nor between boys and girls.

Those pupils who took part in mathematics tutoring were asked (measuring their level of agreement on a 5-point Likert scale) how their understanding changed. Deterioration of understanding is strongly disagreed by most of the pupils ( $AM=4.51$ ,  $SD=1.01$ ), while improved understanding is agreed by the majority ( $AM=2.07$ ,  $SD=1.25$ ). The majority of respondents also strongly disagree that it is shame attending tutoring in mathematics ( $AM=4.52$ ,  $SD=0.99$ ).

The data from items  $c$  and  $i$  in the set A were inverted, so that they support surface understanding as the rest of the items in the set (see Table 4). The item  $a^7$  supports the surface understanding the most (highlighted in the table), on the other hand, items  $d^8$  and  $e^9$  support it the least, therefore, endorse the deep understanding (highlighted in the table). All the other items are placed around the mean (3.0), which means that there is no outstanding trend in them.

	$a$	$f$	$j$	$i$	$g$	$c$	$b$	$h$	$d$	$e$	<i>total</i>
AM	2.25	2.63	2.69	2.78	3.05	3.18	3.21	3.48	3.56	3.70	3.05
SD	1.20	1.19	1.12	3.99	1.03	4.14	0.98	1.25	1.14	1.11	

**Table 4: Items from the set A with their AM and SD**

There was no significant difference between the evaluation by pupils with PST experience and without it. The biggest difference was in the item  $a$ , which was evaluated slightly better by pupils with acknowledged PST experience ( $AM_{\text{with PST}}=2.09$ ,  $AM_{\text{without PST}}=2.39$ ,  $p=0.14$ ).

## Discussion and conclusions

The attendance on PST lessons in Mathematics was acknowledged by almost 46% respondents, which is a bit more than other research shows – Šťastný (2016) claims 36.8% of the respondents took part on PST (and only 53% of these in mathematics), Behr (1990) only 31% of the respondents in Germany. The difference is probably caused by our definition of tutoring, since also tutoring without any financial gain was taken into account in this study. Another reason could be the choice of a sample, since the study was conducted in the capital city. In peripheral areas it may not be so common to attend a tutoring. On the other hand, the study was conducted in the first week of a school year, so it may be expected that more students are about to join tutoring lessons later in the year.

### **RQ1 – Is there any specific kind of understanding that pupils of selected lower secondary schools seek in mathematics?**

According to the data, there is no prevailing tendency towards one type of understanding by the majority of the respondents ( $AM=3.05^{10}$ ). This finding is supported by Skemp (1978), who claims that both types of understanding are useful, and one pupil can actively use both. However, there is a slight tendency that the respondents with PST experience incline a bit more towards a surface understanding (in 7 out of 10 items). The reason why would need some further research, we may only

<sup>7</sup> I am satisfied when I manage to solve a task, even if I don't understand the solution.

<sup>8</sup> It's a waste of time trying to understand how formulas were created.

<sup>9</sup> When solving a task, I only need to know the formula, not why it works.

<sup>10</sup> 1 – preference of a surface understanding, 5 – preference of a deep understanding

assume that one of the reasons can be pupils' attendance on preparatory courses, in which there is often (such as at school) no time for going under the surface of algorithms and procedures (Brousseau, 2002). Another explanation may be that pupils do not even know they do not understand something properly (deeply).

### **RQ2 – Is there any connection between a desired kind of understanding and attendance on PST?**

Taking PST lessons may not be bound to one's desired type of understanding, no connection was found statistically significant. This may be caused by the great range of types of PST which a small number of respondents evaluated. To find any connections among various specific types of tutoring (individual, in a group, at school by their teacher, preparatory courses, etc.) and pupils' notion of understanding, a greater sample of respondents would be needed.

### **RQ3 –Does the attendance on PST change the notion of one's understanding in any way?**

Respondents mostly agree their understanding in mathematics was improved with the help of PST. Nevertheless, by this they can mean both, deep and surface understanding. Further and longitudinal research would be needed to show, if individual preferences in the type of understanding can be changed with the help of PST.

This study has its limitations and it probably poses an equal number of questions as it answers. Due to the lack of research on how one sees the quality of his/her understanding, this study is seen as an exploratory one. Further studies are needed.

### **Acknowledgment**

The study was financially supported by the Grant Agency of Charles University, Faculty of Education (project GA UK No 424119).

*Mathematical identity is understood in this paper as the multi-faceted relationship that an individual has with mathematics, including knowledge, experiences and perceptions of oneself and others. The researchers developed a protocol for accessing mathematical identity, initially designed for use with initial teacher education (ITE) students. The protocol has been refined and its use extended to students of mathematics in other contexts in Ireland. This paper reviews the iterations of the protocol, its development into an instrument, and the context and use of such an instrument. It addresses the issue of robustness of the instrument when applying it to contexts within and outside ITE.*

*Keywords: Mathematical identity, personal narratives, online survey.*

### Introduction

Mathematical identity has been a topic of interest especially over the last twenty years, and many studies have addressed the mathematical identity of teachers or students in initial teacher education (ITE) programmes. The work described in this paper is intended to contribute further to exploring students' mathematical identity. Originally focused on ITE students, it now includes other cohorts.

In 2009, as part of the project MIST (The Mathematical Identity of Student Teachers), a protocol was developed that scaffolded students in writing about their encounters with mathematics. It was used with two groups of ITE students in the island of Ireland (Eaton & O'Reilly, 2009). The aim was to encourage them to reflect on their mathematical identity with a view to facilitating discussions around how that identity may impact on their own classroom practice. The students' narrative responses allowed certain themes to be identified that spanned the responses of both cohorts. These themes also sufficed to describe the results of using a very similar protocol with undergraduate mathematicians taking modules on mathematics education (Eaton, Oldham, & O'Reilly, 2011). For the next iteration, in the study Mathematical Identity using Narrative as a Tool (MINT), the protocol was developed into an instrument that could be administered online, with the aim of accessing further cohorts with greater ease and efficiency. It was used with six cohorts of students in both jurisdictions in Ireland, within and outside ITE (Eaton, Horn, Liston, Oldham, & O'Reilly, 2014, 2015). Details of these cohorts, and of the development of the instrument, are given below.

The main aim of this paper is to address the usefulness of the instrument in a variety of settings. The paper first situates the work of the projects MIST and MINT within traditions of research on identity as distinguished in recent reviews of that research, and then traces the evolution of the

original protocol into the instrument used in MINT. In particular, the authors focus on how the themes identified initially in MIST apply to other cohorts (even outside ITE), and reflect on how robust the outcome themes appear to be, regardless of the cohort of students addressed.

## **Literature review and outline of a theoretical framework**

Research in mathematical identity has attracted, and received, overviews and critical analyses for at least two decades. Earlier syntheses are discussed and expanded in some more recent surveys (Darragh, 2016; Goldin et al., 2016; Hannula, Pantziara, & Di Martino, 2018; Lutovac & Kaasila, 2018). From these overviews, several aspects of relevance to this paper can be distinguished; they provide a framework within which the studies of mathematical identity can be addressed.

A notable aspect is that there is still no agreement on the *definition of mathematical identity*. Darragh (2016) highlights and critiques the differing and indeed conflicting versions, or, in some papers, the absence of any clear definition. In Lutovac and Kaasila's (2018) overview, the uncertainty created by multiple definitions is regarded as a given; however, following Sfard and Prusak (2005), they demand that studies should provide at least a working definition.

Approaches can also be categorized as *broadly social* or *broadly psychological*. Many of the studies on mathematical identity draw on Wenger's (1998) work on communities of practice. In this respect, they tend to follow what Lerman (2000) calls the social turn in mathematics education research that has been a prominent feature especially from the mid-1980s (Goldin et al., 2016). However, Lutovac and Kaasila (2018) argue that "neglecting the individual, i.e. how one thinks and feels and who one is, is at odds with the core concept of identity itself" (p. 767); they advocate for a more balanced psychosocial approach that allows for a focus on individuals' thinking and feeling.

*Methodology* constitutes another aspect. Qualitative approaches have dominated, with sample sizes typically being small, and just a few studies using coding and counting techniques (Darragh, 2016; Goldin et al., 2016; Hannula et al., 2018). The use of narrative has been particularly important; in a seminal paper, Sfard and Prusak (2005) actually take the narratives as constituting identities, hence opening the way to approaches requiring "close attention to the words used" (Darragh, 2016, p. 25).

The *mathematical identity of ITE students* has been a topic attracting considerable focus. The value of research in the area is highlighted, for example by adverting to "some evidence that encouraging pre-service teachers to narrate their own or listen to their peers' personal experiences with the subject makes them cope better, which may lead to the development of a more suitable identity for mathematics teaching" (Goldin et al., 2016, p. 17). Lutovac and Kaasila (2018) also note the process of change in ITE students' mathematical identity, for example by emphasizing affective facets.

## **Methodology and evolution from MIST to MINT**

The *definition* of mathematical identity formulated for the studies considered here is the following:

Mathematical identity is considered as the multi-faceted relationship that an individual has with mathematics, including knowledge, experiences and perceptions of oneself and others.

(See Eaton et al., 2014, for references.) This situated the work primarily in the *broadly social* tradition, with some psychological aspects. The *methodology* has chiefly involved students writing narrative accounts; analysis of the resulting qualitative data has been done by coding and counting as described below. Most work has involved *ITE students*; extension to other cohorts is a focus of this paper.

### **The protocols and instrument, student cohorts, and establishment of themes**

The first study (of three), MIST, considered the identity of ITE students (pre-service primary teachers) who were at one of two institutions – one in Northern Ireland and one in the Republic of Ireland – and were specialising in mathematics (see, for example, Eaton and O'Reilly, 2009). Introductory demographic questions and Likert items were used along with a two-part protocol:

- P1. Students were asked to respond in writing to the prompt: “Think about your total experience of mathematics. Tell us about the dominant features that come to mind.”
- P2. They were then offered a more structured prompt: “Now think carefully about all stages of your mathematical journey from primary school (or earlier) to university mathematics. Consider:
  - Why you chose to study mathematics at third level
  - Influential people
  - Critical incidents or events
  - Your feelings or attitudes to mathematics
  - How mathematics compares to other subjects
  - Mathematical content/topics

With these and other thoughts in mind, describe some further features of your relationship with mathematics over time.”

The narrative responses were used to provide guidelines for focus group discussions, one in each institution. Discussion transcripts, together with the original narratives, were analysed to identify common threads and themes (Clandinin & Connelly, 2000). Using an approach informed by grounded theory, seven themes were identified; their main features can be summarized as follows:

- T1. **Students’ self-reflection on learning and teaching** relates to how students’ exploration of their mathematical identity leads them to deepen their insight into learning and teaching mathematics.
- T2. **The role played by key figures in the formation of mathematical identity** focuses not only on teachers and family members, but also on peers and society at large.
- T3. **Ways of working in mathematics** explores what students find effective in learning mathematics and why, either through individual endeavour or through collaboration.
- T4. **How learning mathematics compares with learning in other subjects** considers the particular characteristics of learning mathematics, usually at school, that distinguish the process from learning in other subject areas.
- T5. **The nature of mathematics** draws from a broad range of students’ perceptions touching on the philosophy of mathematics and on what doing mathematics is about.

**T6. “Right” and “wrong” in mathematics** concerns students’ perception that what is important in mathematics is to find the correct answer, and also a more general notion around the unambiguous nature of mathematical truth.

**T7. Mathematics as a rewarding subject** examines the extent to which students enjoy the subject, often relating to how they persist with it or to significant moments of insight. (Eaton et al., 2011, pp. 156–157)

These reflect both social and psychological aspects. For instance, T4 involves both aspects, and T7 in particular includes affective issues, as highlighted by Lutovac and Kaasila (2018).

In the second study, the students were undergraduate mathematicians at another institution, had elected to take modules in mathematics education, and thus were considered as “prospective” teachers despite not being in an ITE programme. Students wrote responses to P1 and P2 in their own time as part of the module assessment. Analysis was based on the MIST themes, which were found to be adequate for describing these narratives (Eaton et al., 2011; Eaton et al., 2015).

In its third iteration, MINT, the research team of three people – the two from MIST, one from the second study – was augmented to five, with new members coming from two institutions in the Republic of Ireland. The protocol was extended (Eaton et al., 2015) to include a third part:

P3. What insight, if any, have you gained about your own attitude to mathematics and studying the subject as a result of completing the questionnaire?

The items, including introductory demographic questions and Likert items as used for MIST, were gathered into one instrument and made available online to six cohorts of students using SurveyMonkey, allowing students to respond at their chosen time and location. The students in four of the cohorts were in Initial Teacher Education (ITE) programmes. The other two cohorts were not; one comprised first year students of entrepreneurship (involving a one-year business mathematics module), while the other consisted of fourth year students of applied psychology (taking research methods and statistics-related modules in all of their four years of study). For the purposes of this paper, these two cohorts were denoted as Non Teacher Education (NTE).

### **Coding the MINT data**

Of the 99 respondents in the MINT study, 86 provided data (narrative responses) for at least one of the three open questions, P1, P2 and P3; detail relevant to this discussion is provided in Table 1 below. The five members of the research team were assigned respondents, ensuring that the data from each respondent was studied by three people; each person coded the data using the MIST themes and also sought to identify any other themes. No other themes were found. Several meetings were held to compare the coding and reconcile differences; this entailed clarifying the scope of some of the themes to obviate confusion and/or overlap, as elaborated below. Consensus was reached, so the question of inter-coder reliability did not arise. Overall, the seven themes provided adequate descriptions and coverage of the data, though themes T4 and T6 were less prominent than the others. Once the coding was complete for each element (respondent and question, P1-P3) of data, the instances of each theme (T1-T7) were counted. Analysis of data coded T1 (**students’ self-reflection on learning and teaching**) from the 56 ITE students is reported by Eaton et al. (2015).

As regards clarification, when the MINT research team discussed the responses that were potentially to be coded T1, for example, the theme was refined as follows: T1 (i) applied when students explicitly reflected on their mathematical journey with reference to “then” and “now”; (ii) was extended to include reference to how students see themselves teaching and learning into the future; (iii) did not apply to data that comprised lists without context. There was also some development concerning potential overlap of themes, particularly T3 (**ways of working in mathematics**) and T5 (**the nature of mathematics**). The research team agreed that T3 applied to (i) what students did as they learned mathematics, inside or outside “the classroom”, and (ii) what students find effective in learning mathematics and why, either through individual endeavour or through collaboration. Moreover, it was agreed that T3 would include “rote learning” and “learning for understanding” where the learner is the agent (rather than experiencing teaching for rote learning or understanding, for example). In the summary description of T3, it was agreed that “effective” would be interpreted as anything on the spectrum of effectiveness (including ineffective); T5 would include (i) the “relevance versus abstraction” dimension and (ii) applications in the real world. After clarifying such matters in relation to coding, it was judged that the MINT instrument was appropriate for exploring characteristics of mathematical identity among different cohorts of students or in different settings.

### Extending the instrument to NTE students

The application of the instrument to NTE students in MINT is considered in this section, and a comparison is made between the data from this cohort and the ITE data. It was found that the same themes could be applied satisfactorily across the entire MINT study; however, more detailed analysis is of interest.

Cohort (ITE or NTE); questions from protocol (P)	Number of respondents	Percentage of students in each cohort coded in each theme						
		T1	T2	T3	T4	T5	T6	T7
ITE; P1	52	29	44	58	4	17	6	83
ITE; P1, P2 & P3 combined	56	48	84	63	36	38	23	98
NTE; P1	27	22	19	30	4	52	4	89
NTE; P1, P2 & P3 combined	30	63	70	47	33	67	10	97

**Table 1: Coding of themes in response to open questions**

A feature of the protocol (for both MIST and MINT) is that respondents did not see P2 until after they had responded to P1. The importance of this open-ended and non-directive initial question is discussed in Eaton and O'Reilly (2009). Of the 56 ITE students who answered at least one of the three open questions, 52 responded to P1. Likewise, 27 out of 30 NTE students answered P1. On examination of the responses from all six cohorts (four ITE and two NTE), Table 1 summarizes the coding for the themes (T1-T7) for ITE and NTE students, drawing attention to the frequencies of

the codes in responses to P1 and to all three parts (P1-P3) of the protocol combined, as percentages of the number of respondents.

The table reveals that themes T6 and T4 are weakest for each cohort; their frequency is especially low in response to P1. The theme most related to affect, T7, is by far the strongest for each cohort. With the prompts offered by P2 and P3, the codes for each theme are more frequent, as might be expected. However the profile of the two cohorts differs between themes and according to the prompts given. From a qualitative perspective, we should expect that the narrative around mathematical identity would depend on the cohort to which students belong, reflecting factors such as programme focus, teaching culture or maturity of students. To test if there are any significant differences between the ITE and NTE cohorts, a Fisher's exact test was conducted for each of the themes. When all three questions in the protocol were considered together, the only statistically significant difference was for theme T5. NTE students were found to capture this theme significantly more frequently than did ITE students (with  $p = .013$  in the Fisher test). For all other themes there was no statistically significant difference ( $p > .15$  in all cases). However, when the responses to P1 alone are considered, the contrast between the two cohorts in relation to T5 is more stark ( $p = .003$ ), while significant differences between the cohorts in relation to T2 and T3 are apparent (with  $p = .027$  and  $p = .032$ , respectively). This indicates that prospective teachers are more likely to draw attention to the influence of others (such as their own teachers) and to the importance of ways of working with mathematics than are NTE students.

Focusing on T1, it was noted that ITE students' narrative relevant to this theme emphasized how the evolution of mathematical identity from second to third level education was intertwined with their commitment to teaching mathematics (Eaton et al., 2015). Naturally, such a perspective was found to be absent from the NTE cohort. However, significant evolution across the same educational transition was intertwined with the new focus that students appreciated regarding the applicability of the subject to the "real world". It is exemplified in the following quotation from one respondent:

Whereas in Maths in secondary once the problem was solved that was the end of the matter, in college we use the solution after its completion ... and apply them to everyday/business/social scenarios ... My experience of maths in 3rd level has given me a new opinion on the subject, I can clearly see its uses, and an understanding of where to apply them. (P1, NTE)

As far as T5 (the nature of mathematics) is concerned, the importance of application of mathematics to real-world problems comes out strongly for 17 of the 20 NTE students whose responses were coded for this theme. Here is an example of what one student wrote:

Mathematics, in particular statistics is vital within the area of Psychology. I really enjoyed it during third level because I could see what the analyses were being used for. ... Also, while I really enjoy maths now, I feel that the style of teaching through primary and secondary school had given me a complete misconception into what maths really is. (P2, NTE)

In summary, the data show that the NTE students in MINT emphasise the practical nature and importance of mathematics and its relevance to business or psychology. It is reasonable to argue that precisely this aspect gives rise to the much higher instance of T5 among the NTE students than among ITE students.

## Robustness of the instrument

Two aspects of robustness are considered here. They are *robustness of the themes* (their adequacy in describing data for different cohorts), and *inter-coder reliability* in using the instrument.

The seven themes identified in MIST, using a grounded approach following the steps of thematic analysis, were re-evaluated and basically endorsed in MINT by the members of the larger research team. The argument so far has shown that these themes appear to be robust in facilitating access to the mathematical identities of differing cohort of students: ITE students in different types of ITE programme, and in two different (yet neighbouring) countries; and also NTE students who had some element of mathematical work in their courses. No new themes have emerged. While variations are evident in the frequency with which the themes figured for the two cohorts, these could be related to the backgrounds and interests of the cohorts and are of intrinsic interest. It can be noted that placing the instrument online for MINT, using SurveyMonkey, reduced the influence of the researcher and strengthened anonymity for the respondents (as well as allowing them to respond where and when suited them); it also facilitated data collection for the research team.

With regard to ensuring inter-coder reliability, considerable work was needed. Some of this involved clarification of the borderlines between themes, as described above. Future coders might need training, as well as time to grasp the definition or description of each theme. However, while the “coding and counting” approach was important for research, the narrative data elicited can, in any case, be of value for lecturers in appreciating their students’ preoccupations. As judged by answers to P3, it is also of value to at least some of the respondents themselves, in line with the original aims for the studies (and perhaps aligning with the work of Goldin et al. (2016), cited above). In fact (though details are outside the scope of this paper), two of the authors have used the instrument with several cohorts of students, and have found that their own teaching was enriched by what students wrote and that many of them reported finding the exercise helpful.

## Conclusion

The importance of mathematical identity is well established, particularly in teacher education, notwithstanding the challenges in establishing clear definitions and a shared understanding in the academic community. This paper has drawn attention to the development of one protocol and instrument that have proved stable when working with a range of students both within and outside teacher education and in different countries. The online instrument used has elicited both social and psychological aspects of identity. It can be easily administered to students, and allows teachers and even students themselves to gain insight into mathematical identity, which can be beneficial for learning and teaching mathematics. The value of the data collected, for research and also for teaching and learning, promises well for further use in both similar and different contexts.

## Acknowledgment

The authors acknowledge the funding received from SCoTENS for this research, and thank all the contributors to the studies, especially Miriam Liston as a member of the original MINT team.

*This study aimed to explore the structure and level of Grade 10-12 mathematics teachers' epistemological beliefs regarding the nature of mathematics. Data was drawn from the international comparative study New Open Research: Beliefs about Teaching Mathematics (NorBa) investigating mathematics teachers' beliefs in more than 15 countries. A total of 147 mathematics teachers completed the NorBa's questionnaire in Cyprus. Exploratory factor analysis was employed to explore the underlying structure of mathematics teachers' epistemological beliefs and MANOVA was employed to examine for differences in epistemological beliefs in relation to background characteristics. The results are discussed and compared with those of other countries in an attempt to explore for cultural differences.*

*Keywords: mathematics, teachers, epistemological, beliefs*

### Introduction

It is generally acknowledged that beliefs are part of teachers' professional competence. In line with this view, almost all theoretical classifications of teachers' professional competence (e.g. Ernest 1989; Thompson 1992) include, apart from knowledge, teachers' beliefs and attitudes. Beliefs are thought to be crucial to the perception of situations since they influence teachers' choices of actions (Felbrich, Müller & Blömeke, 2008; Felbrich, Kaiser & Schmotz, 2012). Hence, teachers' beliefs play an important role in teaching as they serve as a bridge between teachers' knowledge and their actual teaching (Wilkins, 2008; Felbrich et al., 2012).

Teachers' epistemological beliefs about the nature of mathematics present an issue that has been prominent in empirical research (Felbrich et al., 2008; Felbrich, et al., 2012; Törner & Pehkonen, 1996). In their recent overview of the research literature concerning mathematical epistemological beliefs, Depaepe, De Corte and Verschaffel (2016) state the importance of teachers' epistemological beliefs since these beliefs affect teachers' selection of learning tasks and classroom activities and also influence students' epistemological beliefs. Different categorization schemes for teachers' epistemological beliefs concerning the nature of mathematics have been developed (Ernest, 1989; Blömeke, Felbrich, Müller, Kaiser, & Lehmann, 2008; Felbrich et al., 2012) indicating that teachers differ regarding their epistemological beliefs. It is stated that beliefs have an experiential and context-bound nature and can be understood as socially and culturally shaped mental constructs (Felbrich et al., 2012; Schoenfeld, 1998). Thus, teachers' epistemological beliefs may differ according to background variables or across different countries.

This study focuses on mathematics teachers' epistemological beliefs about the nature of mathematics. Specifically, we investigated the structure and level of 10-12th grade mathematics teachers'

epistemological beliefs. Furthermore, we investigated for differences in these teachers' epistemological beliefs in relation to their background characteristics.

## **Theoretical framework**

### **Teachers' epistemological beliefs about mathematics**

Beliefs in a more broad meaning could be described as “psychologically held understanding, premises, or propositions about the world felt to be true” (Richardson 1996, p.103). In the domain of mathematics, teachers' epistemological beliefs refer to beliefs concerning the nature of mathematics or beliefs concerning the acquisition of mathematical knowledge (Depaepe, et al., 2016; Felbrich, et al., 2012).

Different categorizations for teachers' epistemological beliefs concerning the nature of mathematics have been developed in the respective literature. Ernest (1989) distinguishes between three views on the nature of mathematics: an instrumentalist, a Platonist and a problem-solving view. Another classification is that of Grigutsch, Raatz and Törner (1998) who developed four distinct views on the nature of mathematics: (a) the formalism-related view where mathematics is conceived as an axiomatic system, developed by deduction, (b) the scheme-related view, where mathematics is regarded as a collection of terms, rules and formulae, (c) the process-related view, where mathematics can be understood as a science which mainly consists of problem solving processes and (d) the application-related view, where mathematics can be understood as a science which is relevant for society and everyday life. The formalism-related view corresponds to Ernest's Platonist view, the scheme-related view parallels Ernest's instrumentalist perspective while the process view resembles Ernest's problem solving view (Ernest 1989; Felbrich et al., 2012). Grigutsch et al. (1998) suggested, based on empirical work, that these four views could be subsumed under two perspectives of mathematics: the formalism together with the scheme-related view, describing mathematics as a static science and the process together with the application- related view, characterizing mathematics as a dynamic process. In their study they found that application and process views positively correlated with each other and the same happened with formalism and scheme views. Moreover, they found that the process view correlated negatively with the formalism and scheme orientations whereas there could be no systematic correlation traced between the application view and any other view except for the process view.

Some empirical studies on teachers' epistemological beliefs regarding the nature of mathematics involved teachers at different levels of mathematics education. The study by Felbrich et al. (2008) investigated the structure and level of beliefs concerning the nature of mathematics of future mathematics teachers in Germany at the beginning and at the end of their education and also the epistemological beliefs of their educators in three academic disciplines (mathematics, mathematics pedagogy and general pedagogy). Using an adaptive version of the questionnaire developed by Grigutsch et al. (1998), they confirmed a solution of four factors corresponding to the four categories of teachers' epistemological beliefs. With respect to the overall level of beliefs, both groups of future teachers' highly agreed with process-related statements while they agreed less with scheme-related statements. Another interesting result was that future teachers' views seemed to be dominated by the dynamic aspect of mathematics (process and application) while the static aspect (formalism and

scheme) received less agreement; this pattern was more pronounced at the end of their education. In addition strong positive relations between formalism and scheme as well as between process and application views have been found for future teachers. The belief structure of these future teachers could not be characterized by the two poles as antagonistic (static and dynamic). Mathematics educators agreed with process, application and formalism related aspects and showed a less positive attitude toward scheme-related aspects while educators of mathematics pedagogy hold a more antagonistic view of mathematics as indicated by their preference towards dynamic aspects and relatively lower preference towards the static aspect.

As Depaepe et al. (2016) concluded, research has revealed that it is not easy to describe one's epistemological beliefs as either static or dynamic. Investigating the structure of epistemological beliefs with respect to a different population, this of mathematics instructors at university, Grigutich & Törner (1998) found that the antagonistic structure of beliefs regarding the nature of mathematics could not be found. The epistemological beliefs of these mathematicians could be described by both the dynamic and the static aspect co-occurring at the same time, revealing a complex understanding of mathematics. In the same vein, Roesken and Törner (2010) found that university mathematics teachers can hold simultaneously static and dynamic epistemological beliefs.

Regarding cultural differences, Felbrich et al. (2012) analyzed pre-service primary teachers' epistemological beliefs in mathematics in 15 different countries and investigated whether differences in these beliefs could be explained in terms of cultural differences between countries, using Hofstede's terminology, individualistic versus collectivistic orientation. For this purpose, they used instead of the four views of mathematics the two perspectives, mathematics as a static science and mathematics as a dynamic process, stating that this was more useful in quantitative large-scale research. In individualistic countries (e.g. Germany, Switzerland, Norway), learners are perceived as autonomous subjects acquiring knowledge mainly independently on their own. In collectivistic countries (e.g. Philippines, Thailand, Malaysia) the role of social relationships on the acquisition of knowledge is more prominent. Learners participate in learning due to an obligation towards their teachers, their families and society. The results of the study showed that the epistemological beliefs of these future teachers varied strongly within but also between countries. Future primary teachers from highly collectivistic oriented societies agreed more strongly with the static aspects of mathematics while in highly individualistic oriented societies, the future teachers more strongly stressed the dynamic nature of mathematics. Additionally, in countries that could not clearly be characterized as individualistic or collectivistic, future teachers emphasized both aspects of mathematics to the same extent. The data also showed that future primary teachers with high mathematical content knowledge conceived mathematics as more dynamic in nature compared to the future primary teachers with lower mathematical content knowledge.

Depaepe et al. (2016) stated that there is a strong need for a clear conceptualization of mathematics epistemological beliefs. In addition, the studies concerning mathematicians' epistemological beliefs are rare. Hence, the purpose of this study was to investigate (a) the structure and patterns of the epistemological beliefs for a different population, i.e. 10-12th Grade mathematics teachers in the Cyprus context and (b) the differences in these teachers' epistemological beliefs in relation to their background information.

## Methodology

### Data collection, instruments and participants

According to the Annual Report of the Cyprus Ministry of Education and Culture (2014), the Public Secondary General Education in Cyprus is offered to pupils between the ages of 12 - 17, through two three-year levels: the Gymnasium (Grades 7-9, ages 12-14) and the Lyceum (Grades 10-12, ages 15-17). Currently, there are 38 Lycea and 7 joined Gymnasia and Lycea in Cyprus, where approximately 280 mathematics teachers are employed. In Cyprus, there are minimum requirements to work as a mathematics teacher for grades 7-12 which refer to a bachelor's degree in mathematics and also to the attendance to a one year course in pedagogy offered by the Ministry of Education and Culture.

Data for this study was gathered from mathematics teachers working in Lyceum during the 2015-2016 academic year. The study was conducted in the context of the international comparative study New Open Research: Beliefs about Teaching Mathematics (NorBa) investigating mathematics teachers' beliefs in more than 15 countries. In the context of the NorBa project, a questionnaire was developed and culturally adapted in all participating countries. The questionnaire comprised of seven parts: one of them qualitative and six quantitative (86 items). The current study used data only from two parts (Part A and Part F) of the afore-mentioned questionnaire. Part A collected data on teachers' background variables (gender, age, their teaching experience and highest level of formal education) while Part F explored mathematics teachers' epistemological views on mathematics.

Part F included the shortened version (20 items) of an instrument developed by Grigutsch et al. (1998) also used in Mathematics Teaching in the 21<sup>st</sup> century (MT21) study by Schmidt, Blömeke and Tatto (2011). The formalism-related and scheme-related scales consisted of 5 items each whereas the process-related and the application-related scales were approached using 6 and 4 items respectively. Example items for all subscales are presented below: for the formalism scale, "Mathematical thought is characterized by abstraction and logic", for the scheme scale, "Mathematics is a collection of rules and procedures that prescribe how to solve a problem", for the process scale, "Mathematical problems can be solved correctly in many ways" and for the application scale, "Mathematics entails a fundamental benefit for society". Respondents were asked to show their agreement or disagreement to each item on a five-point Likert scale ranging from strongly disagree to strongly agree.

Informative letters along with the questionnaire and prepaid envelopes were sent to mathematics teachers in all Lyceums inviting them to participate in the study on a volunteer basis. A total of 147 mathematics teachers (44,8 % men and 55,2% women) completed and returned the questionnaire. The response rate was 52,5%.

Various statistical techniques were employed to analyze the data of the current study. Confirmatory factor analysis (CFA) and Exploratory factor analysis (EFA) were employed in order to investigate the possible underlying structure of mathematics teachers' epistemological beliefs, correlation analysis aimed to explore the relationship between the resulting factors and finally MANOVA was employed to investigate for differences in epistemological beliefs in terms of background variables. Data was analyzed using the statistical packages AMOS and SPSS.

## Results

Regarding the first research question of this study, a CFA using AMOS was carried out in order to validate the suggested structure for the 20 items. By employing a maximum likelihood estimation method, three types of fit indices were used to assess the overall fit of the model: the chi-square index, the comparative fit index (CFI), and the root mean square error of approximation (RMSEA). Hu and Bentler (1999) suggest using a combination of cutoff values for the aforementioned fit indices (CFI  $\geq 0.95$  and RMSEA  $\leq 0.06$ ). The model fits the data sufficiently when the ratio of chi-square statistic over degrees of freedom does not exceed 3. A solution with four factors as suggested by the respective literature did not achieve satisfactory fit indices ( $\chi^2 = 272.334$ ,  $df=164$ ,  $p<0.001$ , CFI=0.847, RMSEA=0.068). Therefore, we proceeded with exploratory factor analysis in order to explore a new country-specific structure for the 20 items. EFA was employed on the 20 items of the epistemological beliefs using maximum likelihood with orthogonal rotation (varimax). The Kaiser-Meyer-Olkin statistic (0.77) and Bartlett's Test of Sphericity ( $\chi^2(120) = 694.872$ ,  $p<0.001$ ), indicated that data was suitable for factor analysis. To determine the number of factors to be retained two criteria were used: a) Kaiser's criterion for eigenvalues greater than one and b) the scree plot (Kaiser 1974).

	1	2	3	4
<b>Factor 1: Formalism</b>				
Essential for mathematics is definitional rigor, i.e. an exact and precise mathematical language.	.784			
Fundamental to mathematics is its logical rigor and preciseness.	.744			
Mathematics is characterized by rigor, namely rigor of definition and rigor of formal mathematical argumentation.	.673			
Mathematical thought is characterized by abstraction and logic.	.462			
Hallmarks of mathematics are clarity, precision and unambiguousness.	.410			
<b>Factor 2: Application</b>				
Mathematics helps solve everyday problems and tasks.		.776		
Mathematics entails a fundamental benefit for society.		.755		
Many aspects of mathematics have practical relevance.		.540		
Mathematics is useful for every profession.		.484		
<b>Factor 3: Scheme</b>				
To do mathematics requires much practice, correct application of routines, and problem solving strategies.			.877	
When solving mathematical tasks one has to know the correct procedure else one is lost.			.570	
Mathematics means learning, remembering and applying.			.565	
Mathematics is a collection of rules and procedures that prescribe how to solve a problem.			.517	
<b>Factor 4: Process</b>				
Mathematical problems can be solved correctly in many ways.				.762
In mathematics many things can be discovered and tried out by oneself.				.601
Usually there is more than one way to solve mathematical tasks and problems.				.567

**Table 1: Factor analysis of the epistemological beliefs about mathematics**

In line with respective literature, only items with component loadings larger than 0.30 were retained (16 items). Both criteria supported a four-factor solution explaining 48.08% of the total variance. Factors were named according to the items included in each group. Items that loaded on Factor 1 represent the formalism-related view, items that loaded on Factor 2 represent the application-related view, Factor 3 items represented the scheme-related view and Factor 4 items represented the process-related view. All factors had sufficient internal consistency values (Formalism- $\alpha=0.78$ , Application- $\alpha=0.76$ , Scheme- $\alpha=0.72$  and Process- $\alpha=0.70$ ).

Table 2 presents the mean scores of mathematics teachers' epistemological beliefs for each dimension. Mathematics teachers' epistemological beliefs are characterized by a high level of agreement to statements representing the application and process view. Additionally, they display a strong agreement with statements representing a formalism view whereas they stand somewhere in the middle towards the schematic view.

Scale	Mean	SD
Formalism	4.08	.57
Application	4.46	.46
Scheme	3.47	.70
Process	4.30	.48

**Table 2: Mean estimates for mathematics teachers' epistemological beliefs**

Table 3 presents the correlations between the different dimensions of epistemological beliefs. According to Table 3, correlations were very low and statistically insignificant for the four dimensions concerning the nature of mathematics.

	Scheme	Application	Process
Formalism	.060	.051	.021
Process	-.026	.105	
Application	.040		

**Table 3: Bivariate correlations between the four beliefs concerning the nature of mathematics**

Finally, in order to explore for differences regarding mathematics teachers' epistemological beliefs in relation to various background variables (gender, age, their teaching experience and highest level of formal education), we employed a multivariate analysis of variance (MANOVA). However, we found no statistically significant differences between teachers' epistemological beliefs in terms of these background variables.

## Discussion

In this paper, we investigated the beliefs concerning the nature of mathematics of upper secondary Cypriot Mathematics teachers. Regarding the first aim of the study, the results confirmed a solution of four factors corresponding to the four categories of teachers' epistemological beliefs, suggested by relative literature. These teachers highly agreed with application- and process-related statements, whereas schematics statements were less agreed with. Compared to the results of Felbrich et al.

(2008), the ranking of the four views was slightly different. While in Felbrich et al. (2008) study, the process view received the highest agreement level, in this study the highest agreement level was received by the application view. Cypriot mathematics teachers strongly agreed with both application and process-related statements, perhaps due to the new curriculum which has been implemented since 2011 and follows current trends in education, approaching mathematics as a dynamic tool for thought (Cyprus Ministry of Education and Culture, 2014). More specifically, the new mathematics curriculum has been designed according to principles, such as that students should be involved in mathematical investigations, based on real life situations and that interdisciplinary questions and emphasis should be placed on problem-solving (Cyprus Ministry of Education and Culture, 2014).

The results of the current study showed no statistically significant correlation between the four factors contrary to the results of other studies (Felbrich et al., 2008; Grigutsch et al., 1998). No correlation between the dynamic aspects of epistemological beliefs was also reported in the study by Liebendörfer & Schukajlow (2017). Moreover, the two fundamental dimensions of mathematics, namely the dynamic and the static dimension could not apply to this sample of mathematics teachers, supporting Depaepe's et al. (2016) conclusion that it is not easy to describe one's epistemological beliefs as either static or dynamic. Furthermore, the results of this study supported the results of other studies (Felbrich et al., 2008; Grigutsch & Törner, 1998; Roesken & Törner, 2010) which suggest that mathematics teachers can hold simultaneously static and dynamic epistemological beliefs.

These mathematics teachers agreed with both the dynamic and static epistemological beliefs' dimensions, exhibiting, using Hofstede's terminology, characteristics of both collectivism and individualism aspects. Countries in which teachers adopted both dimensions were also mentioned in Felbrich et al. (2012), with a different population (i.e. future primary school teachers). However, further study is needed using related scales (e.g. Individualism scale of Hofstede) in order to substantiate this argument.

Finally, an interesting result worth mentioning is that no statistically significant differences were found regarding these teachers' epistemological beliefs in terms of background variables (gender, age, their teaching experience and highest level of formal education). These results do not agree with the results reported by Felbrich et al. (2012) in which future teachers with high mathematical content knowledge endorsed dynamic beliefs more strongly than static beliefs. We presume that background variables are shadowed both by the centralized nature of the educational system in Cyprus and the centralized in-service training these teachers' received regarding the new mathematics curriculum.

In conclusion, there is more to be done in this field concerning mathematics epistemological beliefs held by mathematics teachers in various grade levels. More research is also needed regarding the relationship between epistemological beliefs and other beliefs such as teacher authority and self-efficacy beliefs. Moreover, mathematics teachers' epistemological beliefs and their instructional approaches worth more attention since empirical evidence in this direction remains scarce (Depaepe et al., 2016).

*This paper presents the preliminary results of an experimental work conducted on the digital storytelling in Mathematics, as part of the project Prin 2015 “Digital Interactive Storytelling in Mathematics: a competence-based social approach”. In particular, it examines how the immersive aspect of a storytelling can influence students’ engagement and attitude to learning Mathematics by comparing their usual attitude in the classroom. Early findings show that the immersive aspect of the storytelling, together with collaborative work and online interaction, may lead to a change in students’ attitudes towards mathematics.*

*Keywords: Attitude change, storytelling, role taking*

## Introduction

This paper presents the preliminary results of an experimental work conducted on the digital storytelling – as part of the project Prin 2015 “Digital Interactive Storytelling in Mathematics: a competence-based social approach ”<sup>1</sup>. The key elements of the project are in a way expressed in its title’ single terms, which are briefly described below:

- *Mathematics*: object of learning. The focus is on the development of competencies in mathematics (Niss, 2003), starting from a specific mathematical content.
- *Storytelling*: the methodological context in which the teaching/learning process develops. The storytelling has been used since the beginning as a fundamental method enabling knowledge transfer. Its captivating power attracts the students at non-cognitive level of emotions and creativity. In addition, as they enter the story by playing one of the characters, the approach to storytelling is immersive, (Robin, 2008).
- *Interactive*: mode of learner’s participation. In the project, the student interacts with the story, he/she is not simply a listener. Actually, all his/her interaction influences the development of the story.
- *Digital*: the instrumental context in which the teaching/learning takes place. Everything happens in an online digital environment, including storytelling and interaction.

More specifically, the paper takes into consideration the immersive approach of the storytelling, and analyzes the way such an aspect can modify the type of students’ participation compared to how they usually behave in their traditional classroom. For the purpose of our analysis, we have focused on the following research questions: RQ1: How does the immersive approach of the storytelling influence

---

<sup>1</sup> This work is part of the project PRIN 2015 “Digital Interactive Storytelling in Mathematics: A Competence-based Social Approach”, funded by MIUR, effective from 5 February 2017.

learner's engagement in mathematical activities? RQ2: Can the immersive approach of the storytelling change the students' attitude towards Mathematics?

Intending to better explain our research theme, we have referred to a definition of "attitude" towards Mathematics, given by Di Martino & Zan (2007). This definition is based on the following three correlated concepts: learner's emotional disposal, revealed by the expressions "I like/I don't like"; learner's view of Mathematics, reflected by his/her beliefs "Mathematics is..."; learner's view of themselves as learners of mathematics (sense of self-efficacy), revealed by the expressions, "I'm successful/I'm not successful".

## Theoretical background

This work integrates findings from different fields of research and, therefore, cannot be referred to a single theory. Below, we recall the theoretical aspects that are referred to.

Our activity design has mainly regarded collaborative learning, in particular the computer-based collaborative learning (Weinberger et al., 2009), where the need for pre-structuring and regulating social and cognitive processes is even more evident. To this aim, researchers in education have based their study on the concept of *script*, which refers to a sequence of actions directed to define a well-known situation (Schank & Abelson, 1977). Here, each actor has a specific role and specific actions to take part in, and the script is activated whenever one is in a similar situation. In didactics, scripts are imposed externally and support students in a collaborative/cooperative learning context through roles and actions they are required to play and carry out in order to succeed in learning (King, 2006).

The collaborative groups envisages a number of predetermined roles, each of them devoted to a given disciplinary function (Pesci, 2004) such as: *task-oriented*, responsible for all actions oriented to achieve the best result, *group-oriented*, responsible for the communication mood within the group, *speaker*, spokesperson, to speak on behalf of the group about all proposals, *memory*, responsible for saving a written recording of the achieved results, *observer*, responsible for observing all group interactions. Subsequently, a new role, born in the context of an *inquiry* approach (Arzarello & Soldano, 2016) has been added to the initial set, listed above, which we called *devil's lawyer*, i.e. a person who questions about what his/her classmates propose or say, and insinuates doubts.

Concerning mathematics instead, we have referred to the theoretical framework of story-problems (Zan, 2012) placing the mathematical structure in a situation with which the student is familiar and taking the form of a narration. In order to modulate the two dimensions in the text of the problem, Zan suggests the adoption of the C&Q model (Context and Question), as characterized by the following points: There is a story: temporal evolution of a situation, at least one animated character; There is a natural connection between history and question: a character with a purpose and context from which the mathematical problem arises in a natural way; The story is well structured: the parts of a text are linked together; the information has a "narrative" meaning.

## A case study

### The mathematical problem

In order to introduce the students to algebraic modelling, by reasoning and proving, we proposed the following mathematical problem (Iannece & Romano, 2008; Mellone & Tortora, 2015): "*Take four*

*consecutive numbers, multiply the second and the third numbers together and then the first and the fourth ones. Calculate the difference between the two products obtained. Repeat the exercise with four more numbers. Can you observe any regularity?”*

The students are expected to conjecture that the result is always 2 and to prove such a result through the algebraic representation of the generic four numbers as in the sequence  $n \ n+1 \ n+2 \ n+3$ , then the conversion of the given instructions as in  $(n+1) (n+2) - n(n+3)$  and finally the treatment of the found expression, which determines the constant 2. The problem opens up questions of algebraic calculation, as well as linguistic and logical questions associated with terms such as “all” and “always”. It can also be used to stimulate students’ thinking on key mathematical concepts such as the meaning of “consecutive” numbers or the density of rational numbers in  $\mathbb{R}$ .

### The story and its characters

The pedagogical model taken into account for creating the story is the C&Q Model of Zan (2012), as already illustrated in the theoretical background. The entire educational path and specifically the students are immersed in a story. The story, precisely, is set in a Science fiction situation, which sees a group of four friends engaged in the fairly unusual attempt to communicate with aliens from whom they had received mysterious messages made up of numbers and operations (Figure 1).

**Figure 1: The problem**

All roles used in the task, refer to those mentioned in the previous paragraph. It is important to note that the roles of *memory* and *observer*, involved in the activities conducted on digital platforms, are carried out by the platform itself that, at the same time, keeps track of everything happening in the group during the activity. Moreover, since the story makes use of technological tools, basing on previous experiences (Albano, Dello Iacono, & Mariotti, 2016; Albano & Dello Iacono, 2018), we have envisaged a new role, i.e. *technology-oriented*, able to support the teammates and to help them overcome possible problems arising from the use of technological tools. Our four friends correspond to the four roles provided: group-oriented, speaker, devil’s lawyer and technology-oriented, which all have been appropriately contextualised within the story as characters’ profile:

- Marco, called ‘the BOSS’ (i.e. the group-oriented), is the leader within the group of friends, and has won the trust of his teammates for his leadership behaviours;
- Sofia is passionate about reading and writing, she hopes to become a journalist and has got a craze for blogging. In fact, she is called ‘the BLOGGER (i.e. the group-oriented);

- Clara is a wary girl and constantly pesters her classmates with doubts and question; she is ‘the PEST’ (i.e. the devil’s lawyer);
- Federico is a computer enthusiast, convinced of the existence of extraterrestrial lives, he is always fiddling with electronic devices in search of alien signals. That is why he is called ‘the COMPUTER GEEK’, (i.e. the technology-oriented).

The four students of the group, within their Chat discussions, had to agree and chose an avatar that best represented themselves during the progression of the story, depending on the profile they saw as the most matching to their own features. Alongside the four friends, there is an adult, Gianmaria, Federico’s uncle, who is also an expert in computer devices and who loves mathematics. Gianmaria is a teacher/tutor’s avatar and acts as an expert in the learning process.

The story-problem starts with Federico who, fascinated by any possible life beyond the planet Earth, has developed an electronic device in the hope of capturing some signal from the distant sky. Finally, one day, a sequence of characters appears on the screen. (Figure 1). Unfortunately, during data reception the device breaks down and the message remains incomplete. Federico is so much curious as to involve his friends in this adventure, scanning and searching for a meaning to give to those signs and a way to communicate with strangers/aliens. In turn, to get help for the task, the four friends decide to involve their uncle Gianmaria, who accepts and offers them his support in solving the mystery. All interactions among the students and with Gianmaria guide the story flow (and the learning path), and lead them to hold communication with the aliens, after Federico has adjusted the reception device and connected it to their single smartphones. This new feature allows the aliens to send each of them a specific message, such that, in a second phase, they find themselves thinking about different sequences and discovering what they have in common (case of consecutive odd and even numbers, which lead to the number 8).

## Methodology

The general aim of our work is to understand how the role playing and the actions carried out by the students in the Digital Interactive Storytelling environment impacts on their learning. In this paper we focus on the affective aspects of the students’ learning, that is on whether and how these elements can generate changes in their attitude towards mathematics.

The experimentation involved a 9th grade school class from a Foreign Language High School, consisting of 30 students, in the period April-June 2018. With the intention of investigating around our aim, the students were split into groups, each of them corresponding to the original group of the friends (characters) in the story. Each student in a subgroup took on one of the possible roles.

All students participated in the activity, interacting online, at distance, during extracurricular time. The meeting aroused engagement and shared intentionality by the classmates, and stimulated the participants’ interest in investigating the proposal presented by the researchers. In fact, after the meeting, the students could write an article in the school newspaper, in which they state among other things: “We think this method is important, not only from a didactic point of view but also to keep us together and to engage those who usually do not take an active role during the classroom activities. The questions, asked in the form of comics, intrigued them very much, and that first meeting made them impressed” (Figure 2).

**Figure 2: Students' interaction with the problem story**

## Preliminary findings and discussion

This section focuses on the chat interactions of one of the groups of students who participated in the story. The initial step consists in an interview made to the teacher for the purpose of exploring her students' engagement and attitude interacting with the problem story, and also receiving her perceptions of the changes possibly intervened in the students' behaviours.

Let us read an excerpt of a Chat discussion. The role played by each student is reported in brackets:

- |   |                          |                                                       |
|---|--------------------------|-------------------------------------------------------|
| 1 | Dario (Boss):            | What do you do?                                       |
| 2 | Ivana (Blogger):         | I' m a blogger.                                       |
| 3 | [..]                     |                                                       |
| 4 | Dario (Boss):            | A Blogger cannot go any further than the Introduction |
| 5 | Ivana (Blogger):         | How do I select characters?                           |
| 6 | Alessio (Computer geek): | Scroll down page then click on a blue dot and select  |

In the excerpts 4-6, we can observe that Ivana faced with some technical issues, while Dario and Alessio intervened to: first, draw attention; second, help her, according to their own roles. Indeed, Dario takes care of engaging Ivana trying to explain how to solve her technical problems; to this aim he calls upon Alessio. Then, Alessio, playing his role of Computer geek, gives instructions on how to fix the problem.

Despite those initial difficulties, both technical and general, Ivana keeps acting her role: after Dario's affirmation (rows 7-9 below), she synthesizes/reformulates what they expressed in the discussion; in the reformulation she moves from numerical to verbal examples allowing to describe all four cases.

- |    |                  |                                                                                 |
|----|------------------|---------------------------------------------------------------------------------|
| 7  | Dario (Boss):    | 2 is the result of the first operation, i.e. $3*4-5*2$                          |
| 8  |                  | and the results is $12-10=2$                                                    |
| 9  |                  | all the operations are on the right, by doing them all we obtain 2 as a result. |
| 11 |                  | Thus one of the numbers is certainly 2                                          |
| 12 | Ivana (Blogger): | Yes, he has multiplied the product of the means minus the                       |
| 13 |                  | product of the extremes.                                                        |

A change in Ivana's attitude is also confirmed by the teacher's interview.

At the beginning, she did not expect Ivana to choose that role (row 12).

- 14    Researcher:        Do the roles that the students chose reflect what you  
 15                                would expect them to choose? Did their choices surprise you  
                                      considering the roles they normally have in the classroom?  
 17    Teacher:            Ivana's role was a bit of a surprise since she has always  
 18                                been an introverted girl.

Moreover, her changed engagement also impacted on her relationship with the teacher (rows 26-28) and with mathematics:

- 19    Researcher:        Did you find the students involved in the digital activities were more  
                                      engaged than they generally are in other classroom activities?  
 20    Teacher:            After the experience with the digital interactive storytelling, I noticed  
 21                                a change in the way some students relate to me.  
 22                                In particular, there were excellent results from a motivational and  
 23                                emotional point of view: see for example Maria, Ivana, Rosaria whose  
 24                                interaction and engagement in the platform had positive effects not  
 25                                only on their advancement but also on the way they relate to  
                                      mathematics.  
 26                                In a case, for instance, at first Ivana (Blogger) had refused to interact  
                                      with me, after I had asked her to solve an exercise on the blackboard.  
                                      At the end of this experience, she offered spontaneously to do it,  
                                      showing she was no longer afraid of mathematics....  
 29                                Also Maria, witnessed her engagement by saying: "*Teacher, I have  
                                      surprisingly discovered another mathematics*".

Ivana's case was not isolated (rows 20-25). Other students changed their view about mathematics – see for instance what Maria said (row 29) – and also their attitude towards their teacher – see what the teacher perceived of the students' mood through Maria's words.

Furthermore, we investigated whether the students' engagement had somehow been linked to the assessment, asking the teacher if she had used such an element.

- 30    Researcher:        Did you think to include an assessment session to engage students in  
                                      online activities?  
 31    Teacher:            I have always told the students that the online activity is important but  
 32                                I would never use it as an evaluation activity. I would instead assess  
                                      each student on the ground of many elements, not only individual  
                                      tasks or questions, but the way they participate in the activities (in  
                                      class or at home),  
 35                                their attendance and attention.

The above teacher's words suggest that the online activity has been considered as part of a more global evaluation, which takes into account a general active participation in the whole path of didactics of mathematics during the school year. The conclusion that the evaluation had a very low

impact is also justified by the fact that the students continued to participate in the activity even after the end of the school year (rows 44-47).

- 36 Researcher: Did you happen to intervene to prompt student's attention and/or  
 37 participation during the story evolution??
- 38 Teacher: Some groups did it spontaneously, others instead, needed to be  
 39 prompted– we can say that 3 out of 5 groups, moved  
 40 independently and 2 had some technical problems that required  
 41 my intervention and made them unable to hold their rhythm.  
 42 The highest number of notifications occurred after the end of the school  
 year, perhaps because the students had thought that the activity was  
 over
- 44 However, let me underline that the students, even though  
 45 no longer subjected to evaluation, have nevertheless continued to  
 46 interact within the platform being curious about the evolution  
 47 of the story.

Most of the groups involved in the activity proceeded autonomously during the activity flow, without being pressed by the teacher (row 38-39), and slow-downs were only due to technical problems.

## Conclusion

In this work, we have meant to show significant aspects of a preliminary experimentation conducted on a designed digital storytelling in mathematics. The results show that the immersive aspect of storytelling, together with collaborative work and online interaction, typical of platform activities, may lead to a change in students' attitude towards mathematics (RQ2) and in their relationship with the teacher. Today, chat interactions are a familiar context for the students, and even those who get shy in face-to-face situations, may be active participants when interacting online (RQ1). Given the number of students involved in our case study, the results are clearly not generalizable. However, they allow us to identify both the potential of this type of interaction and scenario variables connected with the digital storytelling in mathematics. The interview made by the teacher confirms to be an interesting research methodology that allows us to reflect on other important variables, like the relationship between teacher and students. The preliminary findings will be considered in an experimentation project foreseen for the next phase (March 2019) of the PRIN Project that will involve many schools from different Italian regions. The preliminary results will be also used for defining an adequate experimentation protocol that may enable us to validate our approach on a large scale.

## Acknowledgment

We would like to thank the teacher Rossella Ascione and her students of the I.S. "A. Tilgher" Institute in Ercolano (Italy) who contributed to the realization of this work.

*Many researchers agree that mathematical self-concept is an important factor in (university) learning processes. Mathematics learning at university differs substantially from learning mathematics at school. Especially the character of the learning domain mathematics changes at the transition to university. In this contribution, we present newly developed instruments for self-concept that take the specific character of mathematics at university into account. We applied the instruments in a first-semester course with 344 students. The results of exploratory factor and correlation analyses indicates that it is possible to differentiate facets of self-concept according to different characters of the learning domain mathematics. Finally, we discuss how precise information concerning learners' self-concept can promote to support students at this challenging transition to university.*

*Keywords: Mathematical self-concept, Transition school-university, Mathematical practices, Learning prerequisite.*

## Introduction

There is no doubt that affective variables are important factors in successful, mathematical learning processes (Hannula, 2011). In this contribution, we concentrate on self-concept concerning mathematics. In a recent study, self-concept was identified as an essential learning prerequisite to predict achievement in school mathematics (Feng, Wang, & Rost, 2018). Moreover, self-concept substantially mediates the relation between achievement and emotions (Van der Breek, Van der Ven, Kroesbergen, & Leseman, 2017). Many existing studies deal with the role of self-concept in mathematical teaching and learning processes at school. In contrast, only few studies analyze its role in learning processes at university. As learning processes in these two institutions differ significantly from each other, we claim the need for specific research on the role of self-concept in mathematics courses at university and in particular during the transition to university mathematics.

Questionnaires are the most common instruments to survey mathematical self-concept. The learning domain, for which self-concept should be reported, is mostly broadly described using the word “mathematics”. At the transition from school to university, however, it is not clear if students refer to school or to university mathematics when reporting their self-concept. To obtain a more differentiated insight into students' self-concept, we developed questionnaires for mathematical self-concept that take the specific learning domain at university into account. In this contribution, we present the conceptualization of these instruments in detail. In a study with 344 first-semester students, we studied if the assumed facets of self-concept can be measured and differentiated empirically.

## The role of self-concept in mathematical learning processes

Self-concept, self-efficacy, and self-esteem are important constructs which describe students' views about themselves. The source of students' views about themselves are often experiences of past

success or failure. As self-esteem has a focus on emotions and is not as prominent as the other two constructs in analyzing subject-specific learning processes, we concentrate on the constructs self-concept and self-efficacy. Self-concept has its focus on the persons' skills and abilities, whereas self-efficacy refers to one's beliefs to successfully perform a certain action in the future (Marsh et al., 2019). Researchers use both concepts to explain and predict learners' action and success (Bong & Skaalvik, 2003). As we are interested in students' views of themselves as learners in mathematics at the period of transition, we also want to analyze the sources of students' beliefs about their own mathematical knowledge and skills. That is why we use the construct self-concept. We refer to "mathematical self-concept (of ability)" as *students' beliefs about their own mathematical knowledge and skills*. Theoretically, self-concept is often placed between motivational and cognitive variables, since it is built on views (affect side) which refer to knowledge and skills (cognition side).

One mechanism leading to the relationship between self-concept and achievement might be that learners with a strong self-concept choose to engage in more demanding tasks, which results in better learning and higher achievement. Moreover, there is much evidence that underpins the relation between self-concept and other motivational variables, like interest (Cai, Viljaranta & Georgiou, 2018; Rach & Heinze, 2017). It is assumed that self-concept mediates the relation between achievement and emotions (van der Breek et al., 2017). In university contexts, explorative studies claim that a low self-concept and the decrease of self-concept in the first study year even of students with excellent learning prerequisites probably lead to dropout (Bampili, Zachariades, & Sakonidis, 2017; di Martino & Gregorio, 2018).

However, the studies mentioned above mainly relate to the school context (e.g. Cai et al., 2018). Analyses of learning processes at university often show only weak or non-significant relations between self-efficacy respectively self-concept and study success (Bengmark, Thunberg, & Winberg, 2017; Rach & Heinze, 2017). One reason for this unexpected result might lie in the differences of the learning domain between school and university. When students rate their mathematical self-concept in the first semester at university, they might refer to their beliefs about their knowledge and skills according to mathematics as a school subject, which could be less relevant for learning in this context than self-concept regarding university mathematics.

### **Teaching and learning mathematics at university**

In Germany, as in many other countries all over the world (e.g. South Africa: Engelbrecht, 2010; France: Gueudet, 2008), there seems to be a substantial gap between school and university concerning teaching and learning of mathematics. Not only the social contexts (e.g. the peer group) and the learning opportunities and their use (e.g. from a more guided form in school to a more self-regulated form at university) change at this institutional transition, but also the learning domain itself. At school, one important goal of teaching and learning mathematics is to apply mathematics for solving real-world problems. Thus, classrooms instruction focuses on describing situations mathematically and performing calculations. We call this special character of mathematics "school mathematics". In contrast to that, "university mathematics" denotes the character of mathematics presented in mathematics university courses, which refer to mathematics as a scientific discipline that is built on formal definitions of concepts and deductive proofs (Engelbrecht, 2010). Central practices in the first year of studying mathematics at university include dealing with formal presentations of concepts and proving statements. As demands of proving tasks are mainly high and unfamiliar to freshmen at

university, students often struggle in their first year of university and a substantial share of them drop out from their study program (Heublein, Richter, Schmelzer, & Sommer, 2014).

Summarizing, the learning subject changes at the transition from school to university from a school subject focusing on applications to a scientific discipline focusing on the structure of a mathematical theory. That is why instruments which measure mathematical self-concept in a generic way and results concerning the role of mathematical self-concept in learning processes at school might not be transferable to processes at university.

### **The current study**

As part of the project SISMa (“Self-concept and Interest when Studying Mathematics”), it is the goal of this study to differentiate self-concept concerning different characters of the learning domain mathematics. The aim of the project is to clarify the role of affect in mathematical learning processes during the transition to university mathematics (see Ufer, Rach, & Kosiol, 2017). In this contribution, we focus on mathematical self-concept and present instruments that measure different facets of self-concept according to different characters of mathematics (Table 1, see also Schukajlow, Leiss, Pekrun, Blum, Müller, & Messner, 2012 for a similar approach concerning self-efficacy; see also Ufer et al., 2017 for the construct interest). To measure the different facets of self-concept we constructed two types of scales: The first type of self-concept scales surveys beliefs about knowledge and skills regarding mathematics as it has been experienced respectively anticipated in a specific context. These statements directly address one of the two institutions, in which mathematics is taught and learnt: school versus university. The second type of scales addresses self-concept regarding mathematical practices, which are characteristic for school mathematics (applying mathematics), for university mathematics (proving and dealing with formal representations), or for both contexts (using mathematical calculation techniques). These five scales were developed based on prominent models of self-concept taking into account different frames of reference (Bong & Skaalvik, 2003). In contrast to other scales, e.g. Kauper, Retelsdorf, Bauer, Rösler, Möller, and Prenzel (2012), different aspects of mathematics as points of reference for individual beliefs are specified.

To study whether these facets of self-concept can be differentiated empirically, we conduct a study with first-year mathematics students. The following questions deal with the structure of the questionnaires and the relation of the self-concept measures to other learning prerequisites:

- 1) *Is the theoretical structure of the subscales reflected in the factorial structure of the newly developed instruments?*

We expected that factor analyses would underpin the theoretical conceptualization of the subscales. Moreover, we expected self-concept in applying mathematics to be primarily correlated to self-concept concerning school mathematics and self-concept concerning proving and dealing with formal representations to be primarily related to self-concept concerning university mathematics.

- 2) *Are the different facets of self-concept related to other learning prerequisites?*

We expected that self-concept concerning school mathematics relate to interest concerning school mathematics, the same pattern with university mathematics. In line with previous research (e.g., Cai et al., 2018), we expected a relationship between self-concept measures and mathematical knowledge respectively the school qualification grade.

3) *Is there a relation between facets of self-concept and study choice?*

As a mathematics teacher education program is not as much focused on mathematics as a mathematics bachelor program, we expected that, on average, students with lower mathematical self-concept concerning university mathematics respectively self-concept concerning proving and dealing with formal representations would be more likely to choose a teacher education program. This should result in lower average self-concept concerning university mathematics respectively proving and dealing with formal representations of the teacher education students than of mathematics bachelor students. We had no specific hypotheses regarding self-concept concerning school mathematics respectively concerning applying mathematics and using calculation techniques.

## Method

The sample of this study comprised 344 first-semester-students of the mathematics courses “Analysis I” from one university in the southern part of Germany. In this course, mathematics is presented as a scientific discipline with a focus on formal concept definitions and deductive proofs. We use a complete survey of all students who start their study in a teacher education program or in a mathematics respectively business mathematics bachelor program. As the study took place in the first lecture of the first-semester mathematics courses “Analysis I” and students participated in the survey voluntarily, we can’t say anything about students who did not participate in the study. Most of the participating students were in a teacher education program for two secondary school tracks (Realschule, Gymnasium) in Germany,  $N = 130$ , and in a mathematics respectively business mathematics bachelor program,  $N = 184$ .

Self-concept scale		Sample item	M (SD)	Cronbach's $\alpha$
General		I am very good in mathematics. (4 items)	2.07 (.50)	.76
Institution	School mathematics	The mathematics that I know from school is easy for me. (3 items)	2.35 (.57)	.73
	University mathematics	The mathematics that is done at university is easy for me. (3 items)	1.51 (.65)	.84
Practice	Applying mathematics	Applying mathematics to real-world problems is not so easy for me. (reversed item) (5 items)	2.00 (.51)	.80
	Proof and formal mathematics	Understanding mathematical proofs is easy for me. (8 items)	1.73 (.48)	.82
	Using calculation techniques	I am very good in transforming complex terms. (5 items)	1.91 (.47)	.71

**Table 1: Measurement instruments for self-concept with means, standard deviations, and reliability coefficients,  $N = 252$ -333. Statements rated on a four-point Likert scale from 0 (disagree) to 3 (agree)**

We used a general scale for mathematical self-concept (Kauper et al., 2012, for sample items see Table 1) to compare our newly developed instruments with an approved scale. Moreover, we applied

the new self-concept scales as differentiated measures of self-concept (see Table 1). The participants were asked to assess all mixed statements on a four-point Likert scale from 0 (disagree) to 3 (agree). The individual mean value of a single student on a scale was computed if this student had answered at least half of the items of the scale. We assessed additional affective and cognitive variables in the first lecture: the school qualification grade (grades were recoded so that 4.0 is the best and 1.0 is the worst value), prior knowledge for advanced mathematics, and interest in school mathematics respectively university mathematics (see Ufer et al., 2017).

## Results

### Differentiated measures of self-concept

Table 1 shows the mean values, standard deviations, and reliability coefficients of the self-concept scales. There are no floor or ceiling effects.

Two explanatory factor analyses (Principal Component Analysis with Varimax rotation) – one for the three self-concept scales concerning practices and one for the two self-concept scales concerning the institutions – showed three respectively two factors, that were in line with the theoretical structure of the instruments. Reliability analyses underpin the internal consistency of the general self-concept scale and the five newly developed scales, as all scales show a moderate to good consistency. Correlation analyses also partly promote the expected structure: For example, self-concept concerning proving and dealing with formal representations correlates with self-concept concerning university mathematics strongly,  $r = .65$  (Table 2). The lower correlation,  $r = .26$  between self-concept concerning applying mathematics and self-concept concerning school mathematics was unexpected, because applying mathematics to real-world problems should be a prominent activity in mathematics classrooms. All specific facets of self-concept are correlated significantly and positively with the general measure. In sum, the different facets of self-concept can be separated empirically, and their correlational pattern reflects the assumed specific nature of university mathematics.

	General (SCG)	Application (SCA)	Calculation (SCC)	Proof and Formal (SCP)	School (SCS)	University (SCU)
SCG		.35**	.51**	.49**	.61**	.51**
SCA			.31**	.35**	.26**	.27**
SCC				.38**	.48**	.34**
SCP					.29**	.65**
SCS						.25**

**Table 2: Correlations for the self-concept scales, \*\*  $p < .01$**

### Connection to other learning prerequisites

As expected, correlations of variables focusing the same character of mathematics, school respectively university mathematics, are stronger than correlations concerning variables on different characters of mathematics (Table 3). Only self-concept concerning school mathematics correlates with the school qualification grade significantly. Both self-concept scales weakly relate to mathematical knowledge.

	Interest school	Interest university	Mathematical knowledge	School qualification grade
Self-concept school	.34**	.18**	.13*	.20**
Self-concept university	-.01	.50**	.21**	.05

**Table 3: Correlations of the self-concept scales with other learning prerequisites, \*\*  $p < .01$ , \*  $p < .05$**

### Differences between study programs and study choice

Table 4 shows mean values (and standard deviations) for students from the two programs on all facets of self-concepts. Group differences were tested for significance and we calculated effect sizes.

	General	Application	Calculation	Proof and formal	School	University
Mathematics bachelor program	2.13 (0.55)	2.00 (0.53)	1.88 (0.48)	1.80 (0.48)	2.36 (0.58)	1.61 (0.65)
Teacher education program	2.07 (0.39)	2.03 (0.50)	1.99 (0.46)	1.71 (0.45)	2.40 (0.54)	1.42 (0.62)
<i>d</i>	0.10	-0.05	- 0.23 <sup>t</sup>	0.19	-0.06	0.29*

**Table 4: Mean values (standard deviation) and results of tests of group differences between study programs, \*  $p < .05$ , <sup>t</sup>  $p < .10$**

As expected, students in the bachelor program show a moderately, but significantly higher self-concept than teacher education students concerning university mathematics, and, though not significantly, also concerning proof and formal representations.

### Discussion

While the prominent role of self-concept for successful learning processes at school is well established (Cai et al., 2018), its role in the university context is yet worthy of discussion. With this project, we shed light on the role of self-concept in the transition to university mathematics using differentiated measures of self-concept. Applying newly developed instruments, we distinguish different facets of self-concept of first-semester students and relate these facets to other learning prerequisites respectively the choice of the study program. The results on correlations and group differences provide first evidence that the scales do differentiate between the theoretically conceptualized facets of mathematical self-concept. However, qualifications are warranted for a broad application of the scale. For example, the results indicate that students seem to judge their knowledge and skills to apply mathematics to real-world problems not primarily based on their beliefs about their knowledge and skills regarding school or university mathematics. This might reflect that authentic applications are not considered specific to university mathematics, but also rare in German

school classrooms (Jordan et al., 2008). The small differences in self-concept between the two programs indicate that primarily self-concept regarding university mathematics is related to study choice. This facet of self-concept turned out to be related to prior mathematical knowledge, but not to the school qualification grade. It remains an open question, if the school qualification grade, which predicts success in the first semester above and beyond prior mathematical knowledge (Rach & Heinze, 2017), has an influence on study choice that is not mediated by self-concept. Of course, the results of our study are based on students' self-reports about their self-concept. To get a clearer picture of the impact of self-concept in concrete learning processes, it seems worthwhile to combine our approach with analyzing students' reported experiences and their concrete learning behavior in the first year of study (e.g. di Martino & Gregorio, 2018).

In sum, we presented the conceptualization of instruments to measure different facets of self-concept concerning school respectively university mathematics and corresponding mathematical practices. Using these measures, it is possible in the future (1) to investigate the development of these variables during students' learning processes and their effect on students' learning activities in undergraduate mathematics programs, and most importantly their tendency to drop out of a study program. (2) The differentiated measures may allow more differentiated insights into students' affect. This, in turn, may allow (3) to develop adequate approaches to support students during the challenging transition to a university mathematics program. One idea to support students is to adaptively select mathematical tasks in the courses that fit individual students' prior knowledge so that they can approach these tasks in a meaningful way. If students perceive competence (Deci & Ryan, 2002) when working on these tasks, this should probably lead to the development of self-concept concerning university mathematics, for example mediated by intrinsic motivation (see Krapp, 2005). A higher self-concept, in turn, might lead to a better learning behavior, specifically to students choosing more demanding tasks and showing more perseverance when dealing with these tasks. All in all, such interventions aiming at a higher, yet realistic self-concept, are a promising approach to decrease the rate of students dropping out of mathematics study programs.

# First-person vicarious experiences as a mechanism for belief change

<sup>1</sup>Annette Rouleau, <sup>2</sup>Natalia Ruiz, <sup>2</sup>Cristián Reyes and <sup>1</sup>Peter Liljedahl

<sup>2</sup>Universidad de Chile, Chile: nruiz@dim.uchile.cl; cristian.reyes@ciae.uchile.cl

*Changes of beliefs do not happen arbitrarily; there are underlying mechanisms that enable the shift. This study outlines a problem-solving implementation in which two teachers experienced changes in their beliefs. We describe these belief changes and propose a new mechanism for the shift: first-person vicarious experiences. Our results suggest that, despite their initial uncertainties, teachers who agreed to make a change in their practice underwent a change in belief regarding the efficacy of the practice through first-hand experience of its implementation.*

*Key words: Beliefs, teacher belief change, first-person vicarious experiences, problem solving.*

## Introduction

Underlying the heart of this study is the belief in the importance of problem solving in mathematics classrooms. Widely recognized as leading to a deeper understanding of key mathematical principles and content (Pehkonen, Näveri, & Laine, 2013), problem solving has become an integral aspect of curricular reform (Törner, Schoenfeld, & Reiss, 2007). This has led to an emphasis not only on the teaching of problem solving but on the teaching of mathematics through problem solving (Liljedahl, Santos-Trigo, Malaspina, & Bruder, 2016). Yet ours is not a study of problem solving in mathematics. Rather, it is a study of belief changes that occurred *because of* the implementation of problem solving.

When the Chilean government, in response to deepening concerns over the low results of their students in international standardized mathematics assessments, decided to reform the country's mathematics curriculum, it was the belief in the importance of problem solving that provided direction. Problem solving was seen as integral and with that came the mandate that it be implemented in Chilean primary and secondary classrooms where, prior to this, it had been practically non-existent. (Felmer & Perdomo-Díaz, 2017). It was into this context that ARPA (Activando la Resolución de Problemas en las Aulas/Activating Problem Solving in Classrooms) was born. Developed in response to the mathematics curriculum reform, ARPA is a research and development initiative that seeks to implement teacher professional development (PD) strategies that promote problem solving in an integrated classroom setting (Felmer & Perdomo-Díaz, 2017). Organized as a series of workshops held over the course of 10 months and led by trained monitors, ARPA is based on principles of teachers doing and reflecting. As such, its initial focus is the development of the teachers' own mathematical skills through collaborative problem-solving experiences that incorporate non-routine problems and randomized groupings (see Liljedahl, 2016). This leads to opportunities for the teachers to reflect on their own abilities, their mathematical knowledge, the strategies they used, and the emotions they experienced. This gradually moves to the teachers preparing and implementing analogous collaborative problem-solving activities in their classrooms for all their students. In our study we outline how this reform, predicated on the belief of the importance problem solving in mathematics, resulted in a cascading effect that was felt at the micro level of the classroom. In particular, we focus on the phenomena of belief changes experienced by two teachers as a result of the imposed implementation.

## Framing Beliefs

Writing on beliefs requires treading on shifting sands. One of its challenges is the lack of consensus regarding an accepted definition (Skott, Mosvold & Sakonidis, 2018). Noting the difficulty in reaching a definition that is acceptable across all types of studies and disciplines, McLeod and McLeod (2002) suggest, “There is no single definition of the term “belief” that is correct and true, but several types of definitions that are illuminative in different situations” (p. 118). From Leatham (2006) comes a view of beliefs as anything an individual regards to be true. His sensible system framework for understanding beliefs assumes “that what one believes influences what one does” (p. 92). With this framing of beliefs comes the understanding that beliefs cannot be directly observed but must be inferred. Following Leatham (2006), for the purposes of this study, we call beliefs those things we just hold to be true and must be inferred from what we say and do.

The second area where writing on beliefs requires careful attention is the realm of stability of beliefs. As Liljedahl, Oesterle, and Bernèche (2012) argue, “The field of mathematics education has assumed for too long that stability is an inherent and definable characteristic of beliefs” (p. 101). Their meta-study of beliefs in mathematics education found that stability has many meanings, “from difficult to change, to slow to change, to resistant to change” (p. 112). Further impacting our understanding of the stability of beliefs is Green’s (1971) stress on distinguishing what we believe and how we believe it. He suggests that beliefs that are held evidentially are less resistant to change than are beliefs held nonevidentially. By this he is referring to the basis on which the belief is held—with or without regards to evidence. For Green (1971), beliefs held on the basis of evidence or reason “can be rationally criticized and therefore can be modified in the light of further evidence or better reasons” (p. 48). For example, a teacher may hold an evidentiary belief that group work is untenable because she tried it unsuccessfully once. There is potential to change her belief by providing her with a positive experience with group work. Following Liljedahl et al. (2012) and Green (1971), we propose a further understanding of beliefs as changeable truths that must be inferred from what one both says and does.

## Models of Change in Belief and Change in Practice

Early models proposed that changes in beliefs would lead to change in practice (see Figure 1). Accordingly, teacher PD models focused on occasioning belief changes as a change in belief was seen as a necessary precursor to change in practice (see Philipou & Christou, 2002). However, this does not capture what happened in our phenomenon. As we shall detail later, what we suggest happened for our participants is that changes in practice led to changes in beliefs (see Figure 2).

To better understand this phenomenon, we turn to Guskey (1986) who, noting the abysmal success of PD programs, proposed an alternative model. Arguing that the previous models failed to take into account the process by which change in teachers typically occurs, he proposed a model in which the elements were reordered around student outcomes (see Figure 3).

His model suggests that significant change in teachers' beliefs occurs primarily after they gain evidence of improvement in student learning, which for Guskey can include not only cognitive achievement but also elements such as behaviour or attendance. These improvements typically result from changes teachers have made in their classroom practices—a new instructional approach, the use of new resources, or simply a modification in teaching procedures. It is important to note that, for Guskey, it is not the PD per se, but the experience of successful implementation that changes teachers' beliefs. They believe it works because they have seen it work in their students, and that experience shapes their beliefs. Equally important is Guskey's view of change as gradual and difficult—new practices require incremental implementation.

Liljedahl (2016) also talks about this phenomenon of a change of practice leading to change of belief. He differs from Guskey (1986) in that the participants are asked to implement a practice for which they have no personal certainty will work. In doing so, this method bypasses the classroom norms that frequently act as an impediment to change in practice (Liljedahl, 2016). Liljedahl came to call this a first-person vicarious experience:

They are first person because they are living the lesson and observing the results created by their own hands. But the methods are not their own. There has been no time to assimilate them into their own repertoire of practice or into the schema of how they construct meaningful practice. They simply experienced the methods as learners and then were asked to immediately implement them as teachers. As such, they experienced a different way in which their classroom could look and how their students could behave. (p. 384)

For example, in order to promote the practice of student collaboration, Liljedahl had to first bypass the classroom norm that the doing of mathematics was an individual pursuit. To that end, he had teachers work on problem-solving tasks in visibly random groups during a 90-minute PD session. At its conclusion, the participants were required to introduce visibly random grouping in their classrooms. The result was a significant uptake in the practice that Liljedahl attributes to two factors: (1) the ease of modelling it in a PD setting and (2) the teachers having personally experienced the impact on their own learning when visibly randomly grouped.

Similarly to Liljedahl (2016), the ARPA problem-solving initiative also incorporates Guskey's (1986) notion of changing practice to change beliefs—the teachers in our study were required to implement changes in practice which resulted in changes of beliefs. We were curious about the mechanism behind that change and this curiosity led to our research question: Can we understand their belief changes through the lenses of Guskey (1986) and Liljedahl (2016)?

## **Methodological Considerations**

While the difficulty in ascertaining beliefs is generally acknowledged (Skott, Mosvold, & Sakonidis, 2018), it is argued that qualitative studies have much to offer in the study of beliefs in that they offer a deep understanding of the ways in which people develop and change their beliefs (Olafson, Grandy, & Owens, 2015). For the purposes of our study, talking with the participants and allowing them to tell their stories provided a rich description of the phenomenon and allowed us to respond to our research question regarding the nature of their changes. Note, ours is a small-scale study meant to document the occurrence of a phenomenon rather than its prevalence.

The source of our data was interviews with two participants: Luisa, a primary education teacher who was teaching in a Chilean public school at the time of the study and Josefa, a special education teacher who was assigned to a student in Luisa's fifth-grade classroom. These interviews were originally conducted as part of a larger project that studied the problem-solving experiences of a child with special needs. During their separate interviews, her teachers were also asked a series of questions intended to elicit their perceptions of changes experienced as a result of the problem-solving implementation. Ranging from 40 to 60 minutes in length, the interviews were audio recorded and transcribed in their entirety in Spanish. As this study is an international collaboration conducted by researchers from Canada and Chile, the transcripts were subsequently translated from Spanish to English by a researcher at the University of Chile and later reviewed by another researcher at the University. When first analyzing the interviews, we realized that not only was there a change in the student, but also in her teachers. So, guided by Guskey (1986) and Liljedahl (2016), we reanalyzed the transcripts for evidence of changes in practice. For example, one teacher detailed the change in how she offered a student support in terms of 'before and after'. In keeping with our understanding of beliefs as inferable truths, we attended to those before and after descriptions to establish the teachers' beliefs prior to the change in practice and the resultant new belief.

## Findings

In the following we present two situations, which best exemplify instances in which we noted that an imposed change in practice led to change in beliefs. Each analysis begins with a summation of the original belief and the circumstances surrounding its change.

### Change in teachers' beliefs regarding integration in mathematics classrooms

Prior to participating in ARPA, Luisa and Josefa's students with special education needs were usually taught mathematics using individual materials prepared by Josefa, the special education teacher, in a resource room isolated from the classroom. While both supported integration in theory, they were uncertain whether it could be successful in their classroom. This is common among mathematics teachers with 80% ( $n = 228$ ) holding positive beliefs regarding integration yet less than one-third believing they possessed useful philosophies or strategies to implement its practice (DeSimone & Parmer, 2006). For Josefa and Luisa, this changed when, as part of their commitment to the ARPA program, they prepared and delivered a multi-level problem-solving lesson. Their success at meeting the needs of students with varying levels of ability in this lesson changed their beliefs regarding their own ability to successfully integrate their students. Their theoretical belief in the importance of integration was now reflected in their practice where they moved to a full inclusion model.

One of the expectations of teachers participating in ARPA is preparing lessons incorporating the strategies they have been introduced to in ARPA. At the urging of their ARPA monitor, Luisa and Josefa decided to prepare a public problem-solving lesson. Unique to this lesson was that it was designed to be multi-grade and open to observation by the community. Teachers are sometimes hesitant to prepare materials for multi-level students as they believe the wide range of needs and abilities may be an obstacle to success (Kiely, Brownell, Lauterbach, & Benedict, 2015). Luisa and Josefa were no exception to this belief as we see in this excerpt from Josefa: "*We were worried about the reactions of the girls to working with younger girls*". Luisa was worried in particular about the students with special education needs and felt unsure whether they would be able to contribute

effectively in this type of group dynamic. She was especially concerned for one girl saying, *“Maybe she won’t to be able to talk, because all the other girls do not know her, because they are from second and eighth grade”*. It was concerns such as these that had prevented both teachers from implementing the integration practices that they valued. It is not that the teachers opposed integration, rather they struggled to believe it could be effectively implemented, as Josefa states,

There is this integration and diversity discourse, theoretical stuff, but how do we face it? There is a lot of talk about how everybody is different, that we must work with our diversity, but what I used to do was to bring the girls [with special education needs] to the resources classroom. I’d take them out of the classroom and give them their individual material, that I created and used.

However, despite their uncertainty, they prepared a task in which students from grades 2, 5, and 8 all worked in visibly random groups within their grade levels on the same problem. Both teachers expressed satisfaction with the outcome of the public lesson with Josefa noting, *“And, you know what? Surprisingly, it turned out very well”*. They had observed the students successfully working and learning together regardless of age or ability. Their general fears for the success of the students were eased by observing the students respond to each other as Josefa explains, *“For example, when the fifth-grade girls were in front of the class explaining their solutions, the eighth-grade girls would listen and say: “Hey, I didn’t think about that””*. Their particular fears for their special education students were negated as they watched them be included in the groups and share their contributions. Although initially reluctant to implement this public lesson, its success impacted their beliefs about their own classroom practice with Josefa remarking, *“If we can prepare a lesson for three different [grade] levels, shouldn’t we be able to do that inside the classroom? I mean, it was empirically demonstrated that we can—when you talk about diversity in the classroom—it is obvious that we can do it”*.

Concerning the initial inconsistency between the professed beliefs of the teachers in our study and their actual practice, Leatham (2006) notes that we must look deeper, “for we must have either misunderstood the implications of that belief, or some other belief took precedence in that particular situation” (p. 95). In our study, we found the latter—while both teachers believed that integration of students with special education needs was important, they also held a stronger belief that it only works in theory, which possibly prevented them from enacting their belief in practice. Their involvement with ARPA and its expectation that they integrate all students in lessons offered a first-person vicarious experience that changed their belief regarding the difficulties of integration. This allowed for a match between their professed belief and their actual classroom practice.

### **Change in teachers’ beliefs about low-performing mathematics students**

We view the teachers’ beliefs regarding integration as being contained within a cluster of beliefs that also comprised beliefs regarding low-performing students’ ability to work successfully in collaboration on non-routine problems. Most simply put, they did not believe it was possible. They believed that low-performing and/or students with special needs would be unable to cope with the vagaries of group dynamics and have little to offer in the way of solutions for non-routine problems. Despite these beliefs, and with the encouragement of their ARPA monitor, they changed their mathematics practice to include all students in visibly random groupings that worked collaboratively on non-routine problems. The results surprised them. The students were not only accepted within

their groups, they were viewed as contributing members. Observing the success of their students led both Josefa and Luisa to change their beliefs regarding their students' capabilities.

Luisa recalls that when the ARPA monitor suggested, *"Those children who have more difficulties are the first to solve the problems"*, both her and Josefa's initial response was a disbelieving, *"Yeah, hopefully"*. Similarly, they held low expectations for successful collaboration, particularly for Cristina, a student with special education needs. As Luisa explains, *"Well, I thought her [Cristina's] participation and the acceptance of her classmates would be minimal"*. However, with little expectation of success, they implemented the non-routine problems and visibly random grouping recommended by their ARPA monitor. The teachers were pleased with the results. In particular, Josefa shares that Cristina, the student with special needs, *"has improved a lot. She can solve a problematic situation and face it, read it and look for solutions. She doesn't sit still, she tries to solve it"*. Additionally, Cristina's peers valued her contributions and were willing to work with her in groups too. As Josefa notes, *"Working in groups is like a second-nature to her and she can work in any group"*. Likewise, Luisa recalls the other students saying *"Look, she [Cristina] did it"*. She goes on to add that *"although Cristina wouldn't say 'Girls, let's do it this way', she was making small contributions that were useful for what they were doing as a group"*. Similarly, the teachers observed the success of other low-performing students, like Daniela, who solved a difficult problem. As Josefa explains,

She [Daniela] was present the class when we were teaching the problem of Theresa's floor tiles. Nobody in the class could find the solution. And it is a class where all the girls think they are very good at math. They are very competitive and this girl, Daniela, raises her hand and answers the problem. Luisa and I look at each other surprised.

The teachers came to realize that low-performing students did not need simpler problems, nor special resources, but that they could solve challenging problems. As Josefa notes,

And many times, we had simplifications, we'd plan a simple problem, or with more concrete support, or we'd plan problems with smaller numbers. And we realized it wasn't necessary. Do you get it? That helped us to realize that the students were more capable than we thought. So, you have a different disposition. And according to that, you start giving different support too, things that maybe you didn't even plan, but you go with the flow and you realize that they can do it.

We suggest that it was the change in the teachers' beliefs regarding their students' ability to work on non-routine problems in visibly random groupings that allowed the change in the belief regarding integration to occur. The teachers believed in integration, but until now did not believe they could successfully implement it. To enact their beliefs, the teachers needed the necessary pedagogical knowledge of how to implement practices that support integration (Buehl & Beck, 2015). In speaking of the difference that visibly random grouping and non-routine problems made in the classroom, Josefa explains that *"Those things [visibly random groups and non-routine problems] make the things you want to happen, happen"*. We can infer from this that, within their belief cluster, the successful implementation of integration practices is positioned as an overarching belief—it is the 'thing' they want to make happen. And it happened because ARPA's requirement that the teachers implement specific practices allowed them to observe positive results in their students. This changed their beliefs regarding students' abilities, which in turn allowed them to change their belief of their own ability to

integrate. And as Josefa explains, “*That was a process we had to go through. But it was very good for us*”.

## Discussion and Conclusion

Although not all imposed changes in practice result in changes in beliefs, our participants implemented imposed practices that did change their beliefs. As our data was collected post-hoc, we did not directly observe the changes nor were we able to conduct pre-interviews. However, we were able to infer that, after being asked to prepare and teach a public problem-solving lesson, the teachers changed their beliefs regarding their ability to effectively integrate children with special education needs and their belief regarding the ability of low-performing students. Fitting with Guskey (1986), a partial answer to our research question then, is that their beliefs changed after noting evidence of improvement in student learning. They believed it works because they saw it work and that experience shaped their beliefs. Not fitting with Guskey (1986), however is how the belief change occurred. Guskey (1986) views change as gradual and difficult with new practices requiring slow implementation. Our participants experienced something quite different. There was no gradual assimilation—they were required to change their practice even if they were uncertain about its effectiveness. They were given personal assurances that it would work from their ARPA monitors, but they were not given time to assimilate the methods into their own schemas. They had simply experienced the changes themselves as learners in the ARPA sessions where they were exposed to collaborative problem-solving and then been required to implement the new practice. They had undergone a first-person vicarious experience (Liljedahl, 2016).

Leatham (2006) reminds us that “The challenge for teacher education is not merely to influence what teachers believe—it is to influence how they believe it” (p. 100). To further answer our research question, the findings suggest that first-person vicarious experiences influence the how—the teachers now believe it experientially, which we argue, motivated the belief change. Additionally, the PD aspect is vital as our participants needed to feel or see the changes themselves before their beliefs changed. They still had no certainty it would work in a different context, but they had experienced first-hand that it could. Our findings also suggest that first-person vicarious experiences are effective at altering evidential beliefs—those beliefs that are based on evidence or reason (Green, 1971). For example, the teachers believed that integration only worked in theory because of their previous unsuccessful attempts, which only served to reinforce the belief. Buehl and Beck (2015) would point out quite rightly that the teachers were lacking the pedagogical tools to enact their belief in integration. However, if this was all that was missing, teacher practice would be easy to change. We suggest that they were also lacking a first-person vicarious experience that provided the necessary evidence to change the belief. For our teachers, the success of their public lesson gave them new evidence that they could effectively integrate students and resulted in a change of beliefs.

# **I am scared to make a drawing. Students' anxiety and its relation to the use of drawings, modelling, and gender**

Stanislaw Schukajlow<sup>1</sup>, Judith Blomberg<sup>1</sup>, Johanna Rellensmann<sup>1</sup>

<sup>1</sup>University of Münster, Department of Mathematics, Germany; [schukajlow@uni-muenster.de](mailto:schukajlow@uni-muenster.de)

*Emotions are important for students' learning and achievement. In the present paper, we report on a study of ninth- and tenth-graders (N=194) in which we investigated the relations between anxiety about strategy use, learning outcomes, and gender. We found that anxiety about making a drawing to solve a modelling problem was higher in female than in male students. Further, anxiety about strategy use was negatively related to different indicators of learning outcomes: strategic knowledge about drawing, number of drawings generated spontaneously while solving modelling problems, and modelling performance. Moreover, after we controlled for intra-mathematical performance, strategic knowledge about drawing, and gender, anxiety about self-generated drawing was negatively related to the use of drawings and modelling performance. This finding indicates the importance of anxiety about strategy use for learning and performance.*

*Keywords: Anxiety, Emotions, Strategy, Drawing, Modelling problems*

## **Introduction**

Emotions are important for the learning of mathematics, mathematical achievement, a person's future career, and human well-being (Schukajlow, Rakoczy, & Pekrun, 2017). One of the best-researched emotions is students' anxiety about mathematics. Students have been found to experience test anxiety often, and it can negatively influence students' test performance. However, much less is known about the impact of anxiety on students' strategies. In the present paper, we present a study carried out in the framework of the research project "Visualization while solving modelling problems" (ViMo). The main aim of the ViMo project is to investigate the strategy of learner-generated drawing and its relation to affective and cognitive learning factors. In the present study, we explored anxiety about making a drawing (anxiety about self-generated drawing) and its importance for students' learning outcomes. Our results contribute to clarifying the role of anxiety in strategy use, which was recently identified as an important research gap (Ramirez, Shaw, & Maloney, 2018).

## **Anxiety, drawing strategy, modelling, and gender**

### **Anxiety as an achievement emotion**

Definitions of emotions have emerged from different paradigms, such as the Darwinian, Freudian, or cognitive-psychological traditions (Hannula, 2015). Emotions are typically defined as phenomena that include affective, cognitive, physiological, motivational, and expressive components. The components of anxiety are uneasiness and nervous feelings (affective component), worry (cognitive), avoidance motivation (motivational), anxious facial expressions (expressive), and peripheral physiological activation (physiological) (Pekrun, 2006). In the control-value theory of achievement emotions, anxiety is considered to be a prospective emotion that is related to learning outcomes such as mathematical performance (Pekrun, 2006). Control and value appraisals are assumed to be important for the emerging of

emotions. Students feel test anxiety if they ascribe a high value to an exam and perceive themselves as not able to avoid failure on the exam. Similar to other affective constructs, anxiety has state and trait components that refer to the temporal stability of this emotion (Schukajlow et al., 2017): If students are anxious while solving a specific problem, this is an emotional state; if they are disposed to often being anxious while solving a problem, this is an emotional trait. Another important characteristic of emotions is their object, which varies from more general objects (e.g. the learning of mathematics) to specific objects (e.g. a mathematical problem) (Schukajlow et al., 2017). Mathematical activities (e.g. strategy use) can also serve as objects for emotions.

### **Self-generated drawing and modelling**

Self-generated drawing describes the process and the product of generating an illustration that corresponds to the objects and relations described in a problem (Rellensmann, Schukajlow, & Leopold, 2017), and it has been identified as an important strategy for problem solving (Hembree, 1992). Strategic knowledge makes part of the static knowledge component of metacognition as opposed to the dynamic process component of metacognition, which includes the application of strategies (strategy use). In a prior study, we investigated the importance of strategic knowledge about drawing for solving modelling problems. Modelling problems are problems with a connection to reality, whose solutions require demanding transfer processes between reality and mathematics (Niss, Blum, & Galbraith, 2007). Modelling performance can be clearly distinguished from students' ability to solve problems without a connection to reality, called intra-mathematical performance. Students' strategic knowledge about drawing comprises students' views on the characteristics of a drawing that fits a given problem. This knowledge is positively related to students' performance in modelling problems that can be solved by using the Pythagorean theorem (Rellensmann et al., 2017). Another important predictor of student performance is their strategy use. Students who spontaneously apply a drawing strategy were found to demonstrate higher performance in mathematics than students who did not apply the strategy (Hembree, 1992). However, this finding was not always confirmed when students were asked to construct a drawing. One reason why students do not always spontaneously generate drawings might be their affective perceptions of this strategy such as anxiety about making a drawing to solve a problem.

### **Anxiety, gender, and performance-related outcomes**

Anxiety accompanies solitary problem solving processes (DeBellis & Goldin, 2006), and because working individually is important for gaining new knowledge, different contextual factors have been accessed to explore anxiety in mathematics. One such factor is students' gender. Most studies on anxiety have revealed that female students report a higher level of anxiety in mathematics than male students do (for an overview, see Ramirez et al., 2018). To account for this finding, researchers have primarily discussed two reasons that are both related to stereotypes about gender and mathematics. One explanation refers to the hypothesis that female students report their true level of mathematical anxiety because they do not feel bad about having negative feelings toward mathematics, whereas male students try to repress their anxiety because of the stereotype that males have to be good at mathematics. Another explanation of the higher level of anxiety in women refers to the stereotype that women are

worse at math than men. The crucial role of stereotypes for gender differences in anxiety is supported by the findings that gender differences disappear when students report their real-time (state) anxiety before, during, and after an exam, and they do not have time to reflect on their anxiety (Goetz, Bieg, Lüdtke, Pekrun, & Hall, 2013). Although these findings refer to anxiety about mathematics in general and not anxiety about the use of strategies for solving mathematical problems, we expect similar gender differences for anxiety about self-generated drawing while solving modelling problems.

Anxiety about the use of a specific strategy might be one factor that prevents students from applying this strategy while solving a problem. If a student fears failure when it comes to drawing, he or she might not try to generate a drawing, might solve the problem by using another less effective strategy, or might even give up at the very beginning. The relation between anxiety and students' strategies has rarely been investigated yet. We know that students' negative emotions (including anxiety) seem to impede their use of creative strategies (Pekrun, 2006) such as self-generated drawing. The use of inappropriate strategies is considered to be one factor that can explain why students with high levels of anxiety show poor mathematical performance in primary school (Ramirez, Chang, Maloney, Levine, & Beilock, 2016). However, the negative relation between anxiety and performance depends on students' cognitive abilities and is stronger for students with high working memory capacity. This finding indicates that anxiety about self-generated drawing might be negatively related to students' use of this strategy while solving modelling problems. A similar relation can be expected for strategic knowledge about drawing because students with high levels of anxiety about drawing tend to practice this strategy only rarely and do not have the opportunity to acquire advanced knowledge about this strategy. The relation between anxiety and modelling performance might be negative because anxious students do not make drawings to solve modelling problems. Further, students with high levels of anxiety might perform worse in modelling because their working memory might be overloaded with negative feelings, and they cannot focus on problem solving to the same degree as students who do not feel anxious.

## Research questions

On the basis of prior research, we investigated the following research questions:

1. Does anxiety about self-generated drawing differ for female and male students? We hypothesized higher anxiety for female students.
2. Is anxiety about self-generated drawing related to strategic knowledge about drawing, use of drawings, and modelling performance? We expected a negative correlation between anxiety and these learning outcomes.
3. Is anxiety about self-generated drawing related to the use of drawings and modelling performance after strategic knowledge about drawing, intra-mathematical performance, and gender are controlled for? We expected that the relation would remain negative even after the strategic factor, the achievement factor, and gender were controlled for.

## Method

### Sample and procedure

Two hundred twenty German ninth- and tenth-graders from ten classes in middle- and high-track schools participated in the presents study (mean age 14.9 (SD = 0.64), 109 female students). On the first day of the study, among other questionnaires, students filled out a questionnaire on mathematical anxiety, age, and gender and took a test on strategic knowledge about drawing. On the second day, they worked on a modelling test and an intra-mathematical test. Students were not instructed to make a drawing. Their spontaneous use of drawings was coded by analyzing students' solutions.

### Measures

Anxiety about self-generated drawing was assessed with a new Likert scale that we adapted from the anxiety scale from the Achievement Emotions Questionnaire (Pekrun, Goetz, Frenzel, Barchfeld, & Perry, 2011) by focusing on the items from the drawing strategy. It consisted of five items that ranged from 1 (not at all true) to 5 (completely true) and addressed emotional trait. Example: "When I make a drawing for a difficult word problem, I am very nervous." The reliability (Cronbach's  $\alpha$ ) was .860.

The strategic knowledge about drawing scale was developed and validated in a prior study (Rellensmann, Schukajlow, & Leopold, under review). It comprised eight real-world problems, each of which was followed by an item concerning situational drawings and an item concerning mathematical drawings (see Figure 1). On the 16-item test, students were asked to evaluate the utility of the drawings provided for each problem by comparing the drawings with regard to their helpfulness in solving the problem. Each item consisted of three drawings (a correct and complete drawing, a correct but incomplete drawing, and an incorrect drawing) that students rated on the scale from 1 (not helpful at all) to 5 (very helpful). The scores for each item ranged from 0 to 3, as each item offer 3 comparisons. The number of points depended on the sequence of drawings concerning their usefulness for solving the task. For example, if students identified that the correct and complete drawing was more helpful than the correct but incomplete drawing and that the correct and incomplete drawing was more helpful than the incorrect drawing, they were given 3 points (Cronbach's  $\alpha$  .762).

The modelling performance test comprised eight problems that could be solved by applying the Pythagorean theorem (for an example, see Schukajlow, Krug, & Rakoczy, 2015). Students' solutions were scored by two raters on a scale ranging from 2 (correct problem solution) to 0 (incorrect solution resulting from an incorrect mathematical model or a missing solution). The inter-rater reliability (Cohen's  $\kappa$ ) was  $>.81$  for all modelling problems. Cronbach's  $\alpha$  reliability was .772.

Students' use of the drawing strategy was assessed via the number of drawings they constructed while solving the eight problems on the modelling test. If students made a drawing for a problem, they received a score of 1; if they did not make a drawing, they received a score of 0.

The intra-mathematical test comprised ten items on applying the Pythagorean theorem or solving quadratic equations (e.g.,  $x^2 = 3.8^2 - 2.5^2$ ). They received 1 point for the correct solution and 0 points for an incorrect or missing solution. Cronbach's  $\alpha$  Reliability was .760.

## Statistical analysis

To analyze the relations between the constructs, we used Pearson product moment correlations and partial correlations. Because students worked on the tests on two different days, some data were missing (3% and 8%). Thus, we applied listwise deletion for our analysis. This means that we excluded students from the analysis if they missed the first or second test session, and we performed the analysis on 194 students.

**Wind**

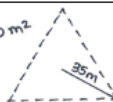

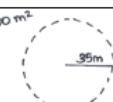

The rotor blade of a 70 m high wind turbine has a length of 35 m and a so-called wind area of about 3,800 m<sup>2</sup>. The wind area is the area that is swept by a rotor blade during a complete rotation. Can the information on the swept area be correct?

**You do not have to solve the task!**

First compare these three drawings with one another. Evaluate how useful each drawing is for solving the task.

Drawings	Not helpful at all	Not helpful	Rather not helpful	Rather helpful	Helpful	Very helpful
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Next compare these three drawings with one another. Evaluate how useful each drawing is for solving the task.

Drawings	Not helpful at all	Not helpful	Rather not helpful	Rather helpful	Helpful	Very helpful
	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

**Figure 1: An item from the knowledge about drawing scale (Rellensmann et al., under review)**

## Results

First, we analyzed the differences in anxiety for female and male students. As expected on the basis of prior research, students' level of anxiety about self-generated drawing was significantly higher for female students ( $M = 2.12$ ,  $SD = 0.96$ ) than for male students ( $M = 1.67$ ,  $SD = 0.63$ ). About 11% of the female students and 18% of the male students denied feeling anxiety about drawing for all 5 statements. The medium effect size (*Cohen's d* = .56) indicates that women feel anxiety more often than men if they make a drawing while solving a demanding modelling problem.

The second research question was about the relation between anxiety about making a drawing and learning outcomes. The analysis of Pearson correlations revealed that students' anxiety about making a drawing was negatively related to all constructs measured in the present study (see Table 1). The effect size for the relation between anxiety about making a drawing and modelling was medium in size, and the effect sizes for the correlations between anxiety, use of drawings, and intra-mathematical performance were weak.

		SKD	UD	IM	MOD
Anxiety	<i>r</i>	-.118	-.154	-.140	-.327
	<i>p<sup>a</sup></i>	.041	.016	.026	<.001

Note. <sup>a</sup> *p*: one-tailed. SKD: strategic knowledge about drawing, UD: Use of drawings, IM: intra-mathematical performance, MOD: Modelling performance.

**Table 1: Correlations between anxiety and the learning- and achievement-related measures**

Students who felt anxious about making a drawing had lower levels of strategic knowledge about drawing, applied this strategy less often while solving modelling problems, and demonstrated poorer modelling performance.

The third research question focused on the analysis of the relation between anxiety about drawing, strategy use, and modelling performance after strategic knowledge about drawing, use of drawings, intra-mathematical performance, and gender were controlled for. The partial correlations confirmed a significant relation between anxiety and the use of drawings ( $r = -.161$ ,  $p = -.026$ ) and between anxiety and modelling performance ( $r = -.236$ ,  $p < .001$ ). The relations between anxiety about drawing and the use of drawings and modelling performance go beyond the contribution of the strategic factor (SKD), the cognitive factor (IM), and gender.

## Discussion

In the present study, we explored the role of students' anxiety about self-generated drawing. Our analyses confirmed the gender differences for anxiety about self-generated drawings that were found for mathematical anxiety in prior studies. Although mean values for anxiety about self-generated drawing were low, our results indicate that more than nine tenths of female students and more than one sixth of male students might be worried, feel uneasiness, or feel nervous while making a drawing for a difficult modelling problem. Giving prior findings about the importance of spontaneous drawings for problem solving (Hembree, 1992) and the importance of drawings for solving modelling problems that can be solved by applying the Pythagorean theorem (Rellensmann et al., 2017), anxiety about using drawings seems to be an important construct that should be investigated in future studies. Moreover, female students might be disadvantaged while solving modelling problems because of their anxiety about using advanced strategies such as self-generated drawing. The main reason for gender differences in anxiety is considered to be social stereotypes that occur in the trait measures of anxiety. In future studies, it will be interesting to assess anxiety about self-generated drawing as a state, directly before or during problem solving, in order to clarify the stability of gender differences.

The analysis of the relations between anxiety about self-generated drawing and learning outcomes was the second main point of the present study. We hypothesized two ways in which anxiety about self-generated drawing can affect learning outcomes. First, students with high anxiety about making self-generated drawings might avoid using this strategy during problem solving because of their fear of failure, and they might look for other ways to solve the problem. The results of our analysis confirmed this hypothesis because we found a negative relation between anxiety and the number of drawings used while solving modelling problems. Moreover, a negative relation between anxiety and strategic knowledge about drawing indicates that students with high anxiety did not know the important characteristic features of good drawings. One reason for this negative relation might be that anxious students make drawings less frequently, and thus, they do not have many opportunities for improving this strategy. The relation between anxiety and the use of drawings while solving modelling problems remained negative after strategic knowledge about drawing, intra-mathematical performance, and gender were controlled for, indicating that affective constructs such as anxiety might influence the use of the strategies beyond strategic knowledge, general mathematical abilities, or gender. Second, anxiety is considered to have a negative influence on performance because it diminishes cognitive resources (e.g. working memory) while problem solving. If students are anxious during problem solving, they cannot focus on the entire problem and perform worse than students who do not feel this emotion. We found a negative correlation between anxiety about drawing and modelling performance that remained significant after strategic knowledge about drawing and intra-mathematical performance were controlled for. This finding might indicate the specific relevance of anxiety about self-generated drawing for students' modelling performance.

In sum, our findings revealed the importance of overcoming anxiety about the use of strategies. In the case of drawing, we suggest that students should learn how to apply this strategy in the classroom and to reflect on differences between more and less helpful drawings. Engagement with drawings should begin in primary school because anxiety about mathematics emerges in the early school years, and decreases performance in secondary school (Ramirez et al., 2018).

Finally, we would like to point out one limitation of the present study. Although anxiety, students' drawings, and modelling performance were ordered along the timeline, we cannot draw conclusions about causal effects of anxiety on the use of drawings or on modelling performance. Prior research has revealed some evidence of reciprocal causation between emotions and achievement (Putwain, Becker, Symes, & Pekrun, 2018). In mathematics, however, the relation between emotions and performance has yet to be clarified. For example, students' prior performance in modelling did not influence enjoyment during lessons, whereas enjoyment during lessons affected modelling performance after mathematics lessons (Schukajlow & Rakoczy, 2016). We interpret this result as evidence of possible effects of anxiety about drawing on performance in modelling. In future studies, we suggest to pay more attention to the interaction of affective, strategic and cognitive factors while solving mathematical problems.

# **Distinguishing engagement from achievement: understanding influential factors for engaged and disengaged low achieving mathematics students**

Karen Skilling

King's College London, School of Education, Communication and Society, London, UK;  
Karen.skilling@kcl.ac.uk

*The engagement construct, comprised of three interrelated components including behaviour, emotions and cognition, is crucial when considering students approach to learning mathematics and by implication, for teaching. In this study, 37 Year 7 students (11-12 years) self-reported measures of engagement and motivation which established unique engagement/achievement groupings. In-depth interviews then investigated factors influencing student engagement distinct from levels of achievement. This paper reports findings from the two low achieving groups differentiated by engagement. The low achieving engaged students reported upwards shifts in adaptive factors: self-efficacy, valuing, task management, persistence and enjoyment, coupled with downwards shifts in anxiety, avoidance, and uncertainty. The low achieving disengaged students reported declines in self-efficacy, valuing, planning and enjoyment with rises in anxiety, uncertainty and self-handicapping.*

*Keywords: Student engagement, mathematics achievement, motivation.*

## **Introduction**

The importance of promoting student engagement, participation and interest in learning mathematics continues to concern mathematics teachers and educators with still too few students continuing to study mathematics beyond post compulsory requirements (Barrington, 2011) and pursuing mathematics related courses and pathways. Increasing student participation in and enjoyment for learning mathematics, addressing declines in student engagement and understanding influencing factors is of central concern, particularly for the transition from primary to secondary school (Martin, Way, Bobis & Anderson, 2015).

Framing student engagement beyond narrow and observable behaviors to include emotional and motivational factors affecting individuals is recognized as fundamental to engagement research. Stipek et al., (1998) identified the 'convergence' and relevance of academic motivation research to reform-orientated mathematics education approaches. In particular, teaching practices emphasising the importance of goal orientations, mastering understanding, risk taking, positive emotions, enjoyment and perceptions of academic competency were seen as beneficial for student outcomes. Subsequent research identifies a lack of relevance, value of mathematics and disaffection with mathematics with students who described mathematics as tedious, isolating, elitist, and depersonalized (Nardi & Steward, 2003). When investigating student emotions, Pekrun & Linnenbrink-Garcia, (2012) revealed a nuanced range of emotions that influence the extent to which individual students participate and engage in mathematics learning. In combination, motivational and emotional factors along with cognitive strategies and approaches of individual students act to shape students dis/engagement profiles. Recent research found that students were more alike in terms of their dis/engagement than their level of achievement (Skilling, Bobis, & Martin, 2015). This

highlights the importance of looking beyond achievement as an indicator of engagement and identifies the significance of investigating engagement levels separate to achievement. This paper incorporates quantitative survey with qualitative interview data of two low achieving students differentiated by their level of engagement. Specific factors underpinning student dis/engagement and how these vary for individual students are revealed. This information is valuable for interventions whereby teachers can purposefully meet students' engagement and achievement needs and is particularly relevant for supporting low achieving students with different dis/engagement profiles.

### **The engagement construct**

Together, aspects of *doing*, *feeling* and *thinking*, comprise the engagement construct, and are referred to respectively as behavioural, emotional and cognitive engagement (Fredricks, Blumenfeld, & Paris, 2004). This multidimensional framework is widely accepted, albeit with variations in terminology and definitions for different types of engagement (e.g. academic engagement is sometimes used). However, clarifying conceptions of engagement, and theorizing about modes of operation and understanding the relationship between engagement and motivation is needed.

For this study, definitions from Fredricks et al.(2004) are adhered to. *Behavioural engagement* refers to participation and involvement in academic and social activities and include, “effort, persistence, concentration, attention, asking questions and contributing to class discussion” (Fredricks et al. 2004; p, 62). *Emotional engagement* is concerned with students' positive and negative reactions to teachers, schoolwork, peers and school and includes non-cognitive aspects such as interest, values and attitudes. *Cognitive engagement* is more strongly linked to improving student learning and draws from two perspectives: the psychological investment in learning that emphasises the efforts students make (Fredricks et al., 2004), and the other focuses on practices used to enhance learning and instruction such as self-regulation strategies and metacognitive processes.

Conceptually engagement is seen to operate in an interrelated way, and is dynamic and likely to fluctuate due to individual factors and varying contexts (school and home). It is also expected that intensities of engagement vary for individual students depending on the types of activities and cognitive demands of tasks. Therefore, the engagement of individual students is expected to fluctuate over time and at different levels of intensity depending on activities, the learning context and motivational factors (Fredrick et al., 2004).

### **Motivation and engagement**

Although the terms motivation and engagement are frequently used interchangeably, they are distinct. Motivation is concerned with the psychological processes of an individual that are the sources for taking actions and displayed as visible engagement characteristics (Skinner & Pitzer, 2012). Therefore, motivations explains why individuals behave in particular ways and are seen as encompassing the internal, private and unobservable factors of the outer, public and observable engagement (Skilling, 2014). Goldin, Epstein, Schorr, and Warner, (2011) also note the importance of considering student engagement in the context of social practices within classrooms and suggest combining motivational and affective structures for creating nine *structures* of engagement. Each *structure* identifies particular characteristics that occur ‘in the moment’ for example ‘Get the job

done'; 'Look how smart I am'; 'I'm really into this' (pp. 549-554) with each emphasising different motivations, features of social situations and subsequent behaviour and emotions.

The direction of underlying motivations leading to engagement (behaviors and emotions) depicted by Goldin et al. (2011) is also discussed by Martin (2007; 2017). Broadly, the motivation and engagement relationship is seen as cyclical, with motivation occurring before and during activities leading to engagement as well as prior engagement explaining "significant variance in subsequent motivation" (Martin, Ginns, & Papworth 2017, p.157). To provide a more integrative approach to motivation and engagement research, Martin (2007) combines multiple motivational and engagement constructs on a single framework, known as the 'Motivation and Engagement Wheel' (MEW). The MEW reflects several important motivation theories that capture both adaptive and maladaptive factors. This framework is also used in the Interview Study as it complements Fredricks et al. (2004) engagement framework and because it includes adaptive and maladaptive factors and therefore addresses both engagement and disengagement constructs.

The aims of the Interview Study were to understand individual, classroom, and school level factors that influence engagement and achievement. The research questions included:

What beliefs do engaging and disengaging students hold about their achievements in mathematics?

What individual characteristics, classroom and home factors differentiate high and low engaging students?

## **Methodology**

The Interview Study reported here used data collected from a related larger project to obtain measures of engagement and achievement of students in Grade 6 (primary school in Time 1) and then Grade 7 (secondary school in Time 2) (11-12 years of age). Following the Time 2 quantitative data collection, in-depth interviews with specific students took place.

### **Identifying specific students participants**

In keeping with the aims of the study it was important to consider engagement and achievement separate from each other. The Interview Study aimed to understand individual students beliefs and characteristics underlying shifts in engagement in the first year of secondary school therefore quantitative data from the Year 7 student group in Time 1 and 2 was drawn upon from the larger project to determine potential participants for interview. Parameters for dis/engagement and achievement were applied to establish students evincing the greatest upwards and downwards shift in dis/engagement and those with the highest/lowest achievement. A further refinement took into account each students mathematical achievement score (out of 30) at Time 2. A tripartite split was set: scores of 18 and over determined high achievers; scores of 13 and below determined low achievers. Using the students engagement/disengagement and high/low achievement characteristics, students were placed into one of the following four categories: high achieving + engaging ('HAE'); low achieving + engaging ('LAE'); high achieving + disengaging ('HAD'); and low achieving + disengaging ('LAD'). In total 37 students from the four categories were interviewed and this is represented in Table 1.

Engaging Students		Disengaging Students	
High Achieving (HAE)	n=9	High Achieving (HAD)	n=8
Low Achieving (LAE)	n=10	Low Achieving (LAD)	n=10

**Table 1: Engaging and disengaging student groupings**

### Data instruments, collection and analysis

The quantitative component of the larger project used a purposively designed survey, called the Motivation and Engagement, Survey (Martin, 2007) known as the MES, and a mathematics achievement assessment instrument to establish shifts in students' engagement, motivation and achievement levels over time and academic year. The MES included 44 items representing 11 first-order factors each representing various constructs of motivation and engagement adapted to a mathematics context (Martin, 2007), against which the students rated themselves from a scale of 1 (strongly agree) to 7 (strongly disagree). The 11 factors are made up of six adaptive factors (self-efficacy, mastery orientation, valuing, persistence, planning and task management) and five maladaptive dimensions (anxiety, failure avoidance, uncertain control, self-handicapping and disengagement) and an additional measure of *enjoyment of mathematics* was included. The mathematics assessment instrument adapted from the Wide Range Achievement Test 3 (WRAT) (Wilkinson, 1983) was used to measure student achievement.

Qualitative data was obtained through in-depth, semi-structured interviews. The interviews involved eliciting student beliefs about their mathematical capabilities, reports on their behaviour in mathematics classrooms and their feelings towards mathematics—and how this affected their engagement and achievement in mathematics. The interviews took place in the final year of term, were recorded on an audio device and later transcribed and supplemented by field notes that recorded information about the students' favourite subject at school, homework habits, and intended career choices. The approach to analysing the interview data was inductive and guided by the interview questions. Comments were coded as being descriptive of an aspect about mathematics learning, such as: liking mathematics; views about mathematics ability; and use of strategies for learning mathematics forming the main themes reported in the findings. Inter-rater reliability was established by following one of the recommendations by Krippendorff (2004) by using an additional coder who independently coded a 13.5% sample of the student interviews and coding reliability an average accuracy of 95.8%, satisfying suggested recommendations.

### Findings and Discussion

This paper draws on the combined quantitative and qualitative results of two low achieving students representative of the LAE and LAD groups. This is a unique approach for investigating the nuance of specific beliefs and characteristics of students with contrasting engagement profiles: student LAE8

is a *low achieving engaged* student and LAD2 is a *low achieving disengaged* student. The measures of engagement and disengagement are presented graphically using spider graphs to illustrate shifts in individual student engagement and disengagement between Time 1 and 2. The spider graphs show adaptive factors (self-efficacy, mastery orientation, valuing, enjoyment, persistence, planning and task management) on the upper semicircle and maladaptive factors (anxiety, failure avoidance, uncertain control, self-handicapping and disengagement) on the lower semicircle. Figures 1 and 2 respectively display the results of student LAE8 and LAD2: the darker line shows Time 1 results: the lighter line shows Time 2. The quantitative data is supplemented by the interview data.

### **Low achieving engaged**

Student LAE8 attended an all male school and was in a mixed ability mathematics class. When asked about favourite subjects, LAE8 reported that mathematics was probably one of his favourite subjects in secondary school because he was “learning a lot of new things” and he “likes to listen and enjoys maths”. LAE8 stated that he would like to do well in mathematics, as “it is good for actual life” and aspired to be an architect. When asked his beliefs about his maths achievement, LAE8 responded, “I go pretty good” and he judged this by reporting that he “usually gets most right” when marking his work in class. When asked if the marks matter, LAE8 replied, “If it’s just normal work and I get 50% I learn to do it again. If it is a test then I know I have [mucked] up” although later in the interview he reports that “Sometimes I make silly mistakes, sometimes I still can’t get it”. These responses indicated that despite not achieving highly in mathematics LAE8 was emotionally engaged in mathematics demonstrating a strong belief in his mathematics ability, he liked learning mathematics and valued its use for the future. These reports are supported by the upward shifts showing high adaptive scores for self-efficacy, valuing and enjoyment in Figure 1.

LAE8 reported proactive behaviors, describing strategies for seeking help at school and home. In class, this included asking the teacher for further explanations because “sometimes she explains it in a way I can understand”. Other strategies included: going through his notes: spending “some more time on it” to see if he could “get it”; or going around the class to see “if other people might know”. LAE8 reported that if he needed help at home with maths he could ask both his mum and dad stating, “my parents help me a lot”.

Although LAE8 believed that “we [the class] get a lot of homework” he reported planning time after school to attend to this. He reported using the textbook for support by referring to examples asking the teacher in the next mathematics lesson. The actions taken by LAE8 indicated active behavioral and cognitive engagement by planning to do maths work in class and at home, persistence with trying to complete work rather than avoid it. These behaviors are reflected in Figure 1, where shifts in higher measures for planning, task management and persistence and downward shifts in measures for avoidance and self-handicapping are evident. Further, LAE8 did not report feeling anxious but portrayed a positive attitude towards mathematics learning. LAE8 was also able to describe students he believed were not engaged or motivated in class reporting, “sometimes they just don’t want to listen. They usually muck around when the teacher is explaining on the board”. This description contrasts with how LAE8 describes himself indicating high levels of behavioral, emotional and cognitive engagement.

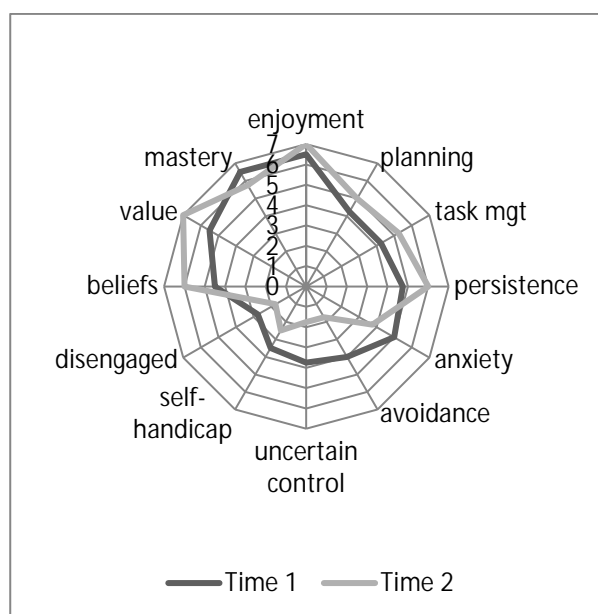

Figure 1: Low achieving engaged (LAE8)

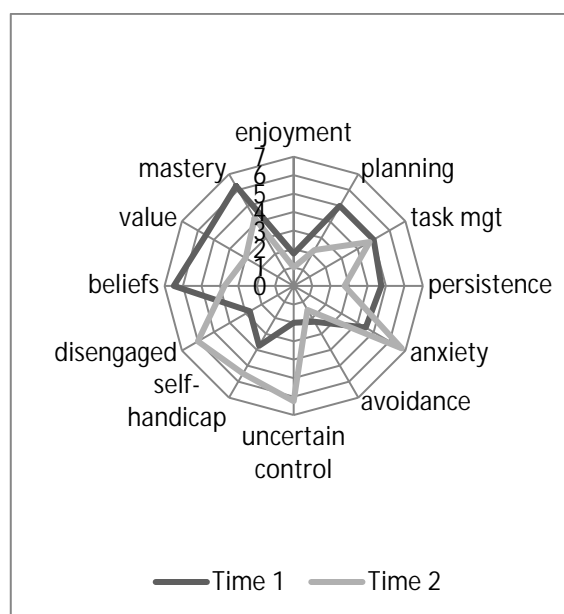

Figure 2: Low achieving disengaged (LAD2)

### Low achieving disengaged

LAD2 attended an all female school and was also in a mixed ability class reports a contrasting report from that of student LAE8. Despite scoring several marks higher than LAE8 in the Time 2 maths quiz, when asked how she felt about mathematics LAD2 reported “I don’t really like it” explaining “I think it’s boring and I don’t really get it”. She was aware of her lack of understanding, stating that when the teacher “tries to explain something I don’t understand it and some of the bookwork I don’t understand”. LAD2 reported that she rarely asked the teacher for help, preferring to ask her friend “because she gets good grades” or looks at examples in the textbook. When asked to describe her achievement in mathematics LAD2 responded, “I don’t really think I do good. Like I get bad marks in it. I get 10 out of 30 for a quiz or something” and placed herself as “sort of near the bottom” of the class. Although LAD2 reported that she continued to try she also said that she is not engaged or motivated by mathematics. When asked about her future intentions for studying mathematics she reported, “I don’t want to...because I don’t find it very interesting”. LAD2 also commented that she finds mathematics “confusing” and this make her “feel annoyed and angry” explaining “I’m angry at it because I want to get it”. These descriptions by LAD2 of her mathematics experiences in Year 7 relate negative emotions and are reflected by reduced measures in several adaptive factors in Figure 2, particularly in self-efficacy, valuing and enjoyment. Significantly, there are also large increases in maladaptive measures such as anxiety, uncertain control, self-handicapping and overall shifts towards disengagement.

In class, LAD2 finds that when the teacher starts a new topic although she doesn’t really “get it” she tries to ask the teacher questions but reports: “You will have your hand up for 15 minutes and he won’t pick you. So, I put it down and ask someone else”. LAD2 said that she did homework “most of the time but sometimes” she just does not “get it” and then tends to “give up”. At home, LAD2 reported that she can talk to her dad about mathematics but does not do this “very often” and although

the school offers students an online mathematics programme for use at home she does not use it. Regarding homework, LAD2 says that when given work from the textbook she rarely completes this or follows up for explanations. She also finds that the textbook “doesn’t really explain it properly” resulting in not understanding the topic and “the whole chapter”. LAD2 believed that her achievement was lower than in primary school reporting, “last year I did average...but this year I have gone down”. This shift has led to her feeling that mathematics is now a “bit harder”, and that she “understood it more” in primary school where the teachers explained mathematics better as they “drew it on the board and explained it again”. LAD2 summarized her thoughts as: “last year I felt oh yeah, I am doing alright but this year, oh my god I am doing badly”.

In summary, by investigating the reports of these two students with similar achievement but differing engagement levels, insights for understanding influential motivational, class and home factors are revealed. For example, student LAE8 showed higher measures across most adaptive factors and declines in maladaptive factors between Time 1 and 2. He also portrayed a positive approach and enjoyed mathematics while demonstrating proactive behaviors and using cognitive strategies for monitoring and regulating his learning. In contrast, the disengaged student, LAD2 evinced large shifts in maladaptive measures particularly anxiety, control and self-handicapping. Unfortunately, this student also reports strong negative emotions such as dislike, confusion, and frustration that seem to stem from her lack of understanding and strategies for addressing the mathematics being taught.

## Conclusion

In combination, the quantitative survey data effectively measured shifts of adaptive and maladaptive factors for individual students. Analysis of these measures assisted in identifying students with pronounced positive and negative shifts in engagement in mathematics over one year. This provided for a unique and purposeful qualitative investigation of two low achieving students with different engagement characteristics. These characteristics were explored using in depth interviews to better understand their beliefs about mathematics competency, feelings towards mathematics and strategies for approaching mathematics learning (Goldin et al, 2011; Nardi & Steward, 2003; Martin et al, 2015). The findings revealed that although both students were low achieving, the engaged student reported a stronger sense of self-efficacy, valuing, persistence, enjoyment and task management. The low achieving disengaged student however, reported declines in self-efficacy, valuing, enjoyment and planning and increases in anxiety, uncertainty and self-handicapping. This information highlights the individual variation in student engagement characteristics despite displaying similar levels of achievement and reveals vital information for teachers when planning instruction with a view to improving individual student learning outcomes (Stipek et al, 1998) and for maintaining student interest and participation in mathematics (Barrington, 2011).

*Motivational variables such as self-concept and interest accompany learning processes and hence are considered as relevant target variables of schooling. In order to evaluate effects of a teacher training on their students' domain-specific self-concept and interest, established mathematics-related scales for these variables were adapted to the domain of functions and administered in a pre-, post-, follow-up-design to a sample of 1177 secondary school students. Results of confirmative factor analyses in Mplus indicate that the scales mathematics- and functions-related self-concept and interest are empirically separable despite relatively large latent correlations for the functions-related scales in the pre-test. Together with satisfying values of Cronbach's alpha, this finding implies that the instrument can be used to reliably assess students' functions-related self-concept and interest and hence fulfills the requirements for further analysis steps.*

*Keywords: Confirmative factor analysis, self-concept, interest, mathematics, functions.*

## Introduction

The project ProfiL9 of Heidelberg University of Education evaluates the effects of a teacher training about learning difficulties related to elementary functions (e.g., Sproesser, Vogel, Doerfler, & Eichler, 2017). The field of functions was chosen because of its relevance within mathematics (education) and its difficulty for many students (e. g. Selden & Selden, 1992). Effects of this teacher training are to be evaluated both at the teacher and the student level. Beyond investigating students' competency development related to elementary functions in the course of the corresponding teaching unit, this study focuses on changes in students' self-concept and interest. In the context of assessing effects of teacher trainings at the student level, Yoon and colleagues (2007) state that the corresponding instruments have to meet high scientific standards. Hence, a reliable and valid instrument is mandatory. In order to get insight in particular cause-effect-relations, such a test instrument should target variables directly related to the subject of the teacher training, in the present case related to the mathematical subdomain of functions. This paper presents results of a confirmatory factor analysis showing that self-concept and interest for mathematics in general and functions in particular are empirically separable within our sample. Therefore, in the next section, we will introduce the theoretical background related to self-concept and interest. Afterwards, we will outline the methods of this study and finally present and discuss our findings.

## Theoretical Background

Motivational dispositions such as self-concept and interest nowadays are considered to be relevant for learning (e.g., Schiefele, 1991; Valentine, duBois, & Cooper, 2004) as they accompany learning processes and affect (the development of) students' achievement in and beyond school (e.g., Jacobs,

Lanza, Osgood, Eccles, & Wigfield, 2002). Therefore, they represent important target variables also of mathematics schooling (e.g., Pekrun & Zirngibl, 2004). In the following, the motivational variables self-concept and interest will be described in more detail.

An individual's beliefs about the own abilities in a particular academic or non-academic domain are subsumed as *self-concept* (e.g., Bong & Skaalvik, 2003). Among other self-belief constructs domain-specific self-concept can be considered as ranging between the more general self-esteem, i.e., an “emotional attitude towards the self” (ibid., p. 11) and the more particular self-efficacy expressing a conviction of how to perform in a concrete task. Self-concept is considered to be relatively stable and based on prior (achievement) experience in the corresponding domain (ibid.) on the one hand. On the other hand, there is a reciprocal relationship between self-concept and achievement: achievement in a certain domain is clearly influenced by prior self-concept levels (e.g., Calsyn & Kenny, 1977). An example for domain-specific (academic) self-concept is mathematics-related self-concept, i.e., a person's confidence in his or her abilities in mathematics. Such domain-specific self-concept was found to be positively correlated to achievement in the corresponding domain (e.g., Baumert & Köller, 2000), because – for instance – a positive self-concept can support success-oriented behaviors like practicing (Valentine et al., 2004). Because of the domain-specificity of self-concept, e.g. Marsh and Craven (1997) recommend that researchers should measure this variable as closely connected as possible to the domain focused in the corresponding research.

According to Schiefele (1991, p. 302) individual *interest* is a “relatively enduring preference for certain topics, subject areas, or activities”. Hence – similarly to self-concept – individual interest is domain-specific and it makes sense to assess it closely related to the corresponding domain. Moreover, Schiefele (ibid.) states that an interested person attributes a personal relevance to his or her target of interest (i.e., value-related valences) and that interest usually is accompanied by positive feelings such as involvement and enjoyment (i.e., feeling-related valences). Therefore, an interested person engages in an activity or subject for its own sake and makes efforts in order to learn about it. Various studies show that interest and achievement are correlated (e.g., Baumert & Köller, 2000; Helmke & Weinert, 1997). Schiefele (ibid.) gives several reasons for this relationship: For instance, interested students are more likely to employ meaning-oriented learning activities and they use more elaborated learning strategies. In the present study, we focus on the relatively stable (individual) interest for the domain of mathematics and functions as opposed to the more fluctuating situational interest (e.g., Hidi & Renninger, 2006) that won't be considered here.

In order to investigate certain cause-effect-relations, it makes sense to measure self-concept and interest particularly related to the focused domain (cf. Bong & Skaalvik, 2003; Marsh & Craven, 1997; Schiefele, 1991). This consideration does also reflect the finding that empirical correlations, e.g., between self-concept and achievement are found to be larger when these variables are measured as domain-specific as possible (Hansford & Hattie, 1982). As stated above, self-concept and interest differ between certain school subjects such as Mathematics and English. In this sense, it can be assumed that students can also hold different perceptions of, e.g., particular mathematical subdomains such as functions with regard to these motivational variables. However, this assumption still has to be verified empirically. Considering all combinatorial possibilities, the following alternatives appear to be particularly plausible: As mathematics and its subdomain of functions as well as self-concept

and interest are closely connected, it is possible that students do not differentiate between these variables at all. A second possibility is that they discriminate between self-concept and interest but do not perceive mathematics distinct from functions as the latter represents a subdomain of mathematics. A third possibility is that students perceive mathematics distinct from functions but do not discriminate between self-concept and interest within each domain. A fourth possibility is that students discriminate between self-concept and interest within mathematics because they have long-time experiences with this subject. However, and due to less experience with the domain of functions, self-concept and interest related to this domain could be not distinguishable for them. The latter possibility of students being not able to distinguish between self-concept and interest related to functions particularly applies for the data collection before the teaching unit of functions when students were not familiar with this domain.

### **Research questions**

Concerning the domain of mathematics, motivational variables have been examined by various studies including PISA and TIMSS; they document for instance considerable correlations between self-concept, interest and achievement (e.g., Baumert & Köller, 2000; Pekrun & Zirngibl, 2004). However, to our best knowledge these variables have not been investigated specifically related to the mathematical subdomain of (elementary) functions and hence there are no approved instruments to reliably measure them. Taking into account that self-concept and interest are both domain-specific, it is reasonable to assess these variables related to the particular domain of functions (cf. Marsh & Craven, 1997) for investigating the above assumption that students can hold different perceptions of mathematics and functions with regard to their self-concept and interest. In this study, we investigate the following research questions:

- Are mathematics- and functions-related self-concept and interest empirically separable?
- How reliable do the scales measure these variables?

### **Methods**

#### **Sample and context of the study**

In this study, data from 1177 German students (45.6 % female) from 53 classes in 32 German secondary schools was analyzed. Due to missing values the concrete number of subjects varies for the different analyses and hence is indicated in the corresponding part of the Results Section. The classes were recruited among teachers that participated in the teacher training mentioned above as well as from schools that were in contact with the project contributors. In both cases, the participation of the classes and the individuals were voluntary. The students were aged between 11 and 17 years ( $M = 13.20$ ,  $SD = 0.94$ ). The large range of age is due to the fact that in Germany the teaching unit of linear functions is taught in different grades (mainly in grade 7 and 8) depending on the level of academic performance of the corresponding class or school, respectively. In all the participating classes, the assessment was done before (pre-test) and after (post- and follow-up-test) the teaching unit of linear functions as it focuses on the development of functions-related competence and motivational variables in the course of this teaching unit. As many students were not familiar with functions at the pre-test, they were told that the tasks focusing on interpreting graphs in the preceding

competency test were examples for functions tasks. Moreover, they were given the option not to answer the functions-related items if they did not feel comfortable responding to them. In each class a regular teacher of the corresponding school as well as a researcher (the first author or a specifically trained assistant) were present during the testing.

## Measures

Motivational variables referring to mathematics and functions were assessed using 5-point Likert scales. Mathematics-related self-concept (6 items) and interest (3 items) were measured through scales established by Pekrun and colleagues (e.g., 2007). In order to tap students' self-concept (6 items) and interest (3 items) related to functions, the mathematics-related items were adapted to the mathematical subdomain of functions. More information about the scales, e.g., sample items are displayed in Table 2 in the Results Section.

## Analyses

The confirmatory factor analysis (research question 1) was conducted with the software Mplus 7.3 with type = complex which accounts for nested data in school classes. The implemented Full Information Maximum Likelihood (FIML) procedure estimates missing values except for cases with missing on all variables. The robust maximum likelihood (MLR) estimator was used which corrects for non-normality in the measures. For each factor, the regression weight of one item was fixed to 1.0 by default. In order to assess global model fit, we refer to the comparative fit index (CFI), the root mean squared error of approximation (RMSEA) and the standardized root mean squared residual (SRMR). Hu and Bentler (1999) suggest using a combination of cutoff values such as  $CFI \geq 0.95$ ,  $RMSEA \leq 0.06$  and  $SRMR \leq 0.08$  for a good model fit. As the  $\chi^2$  statistic is sample-size dependent the  $\chi^2/df$  ratio was additionally determined. According to Bollen and Long (1993) the model fits the data sufficiently when this ratio does not exceed 5. The different (nested) models are furthermore compared by the sample-size adjusted Bayesian Information Criteria (adj. BIC). Values for Cronbach's alpha (research question 2) were determined with SPSS 25.

## Results

Research question 1 investigates whether the mathematics- and functions-related scales were empirically separable within our sample. For this purpose, we specified several models with the items for mathematics- and functions-related self-concept and interest as stated above: Model A integrates all 18 items to a single factor. Model B assigns the items to the two factors self-concept (for mathematics and functions) versus interest (for mathematics and functions). Model C differentiates between mathematics (self-concept and interest) and functions (self-concept and interest). Model D contains three factors, namely self-concept for mathematics, interest for mathematics and a combining factor for functions (self-concept and interest). The full Model E incorporates the four factors mathematics-related self-concept, mathematics-related interest, functions-related self-concept and functions-related interest. Details about the fit of these models are displayed in Table 1 for the pre-, post- and follow-up-test. Concerning all times of testing, global fit indices ( $\chi^2/df$ , CFI, SRMR, RMSEA) indicate except for slight deviations that the full Model E fits the data reasonably whereas the other models do not meet most of the recommended thresholds (see Analysis Section). Similarly, model comparisons based on the adjusted BIC are in favor of Model E.

Model	Pre-test (N = 895)	Post-test (N = 915)	Follow-up-test (N = 708)
Model A (1 factor): Self-concept and interest for mathematics and functions	$\chi^2/df = 23.2$ CFI = .658 RMSEA = .157 SRMR = .128 Adj. BIC = 37901.3	$\chi^2/df = 22.2$ CFI = .728 RMSEA = .152 SRMR = .102 Adj. BIC = 40697.5	$\chi^2/df = 18.9$ CFI = .707 RMSEA = .159 SRMR = .101 Adj. BIC = 31181.1
Model B (2 factors): self-concept for mathematics and functions vs. interest for mathematics and functions	$\chi^2/df = 22.5$ CFI = .671 RMSEA = .155 SRMR = .124 Adj. BIC = 37676.6	$\chi^2/df = 18.0$ CFI = .783 RMSEA = .136 SRMR = .093 Adj. BIC = 39950.0	$\chi^2/df = 15.6$ CFI = .763 RMSEA = .144 SRMR = .090 Adj. BIC = 30536.4
Model C (2 factors): self-concept and interest for mathematics vs. self-concept and interest for functions	$\chi^2/df = 7.0$ CFI = .908 RMSEA = .082 SRMR = .053 Adj. BIC = 35182.2	$\chi^2/df = 12.7$ CFI = .851 RMSEA = .113 SRMR = .069 Adj. BIC = 38946.2	$\chi^2/df = 10.7$ CFI = .843 RMSEA = .117 SRMR = .068 Adj. BIC = 29724.9
Model D (3 factors): self-concept for mathematics vs. interest for mathematics vs. self-concept and interest for functions	$\chi^2/df = 4.7$ CFI = .944 RMSEA = .064 SRMR = .042 Adj. BIC = 34779.3	$\chi^2/df = 10.0$ CFI = .887 RMSEA = .099 SRMR = .059 Adj. BIC = 38464.1	$\chi^2/df = 8.3$ CFI = .884 RMSEA = .101 SRMR = .059 Adj. BIC = 29322.7
Model E (4 factors): self-concept for mathematics vs. interest for mathematics vs. self-concept for functions vs. interest for functions	$\chi^2/df = 3.3$ CFI = .967 RMSEA = .050 SRMR = .033 Adj. BIC = 34536.7	$\chi^2/df = 5.3$ CFI = .948 RMSEA = .068 SRMR = .038 Adj. BIC = 37661.5	$\chi^2/df = 3.8$ CFI = .957 RMSEA = .062 SRMR = .033 Adj. BIC = 28588.6

Table 1: Global fit indices for the tested models (pre-, post- and follow-up-test)

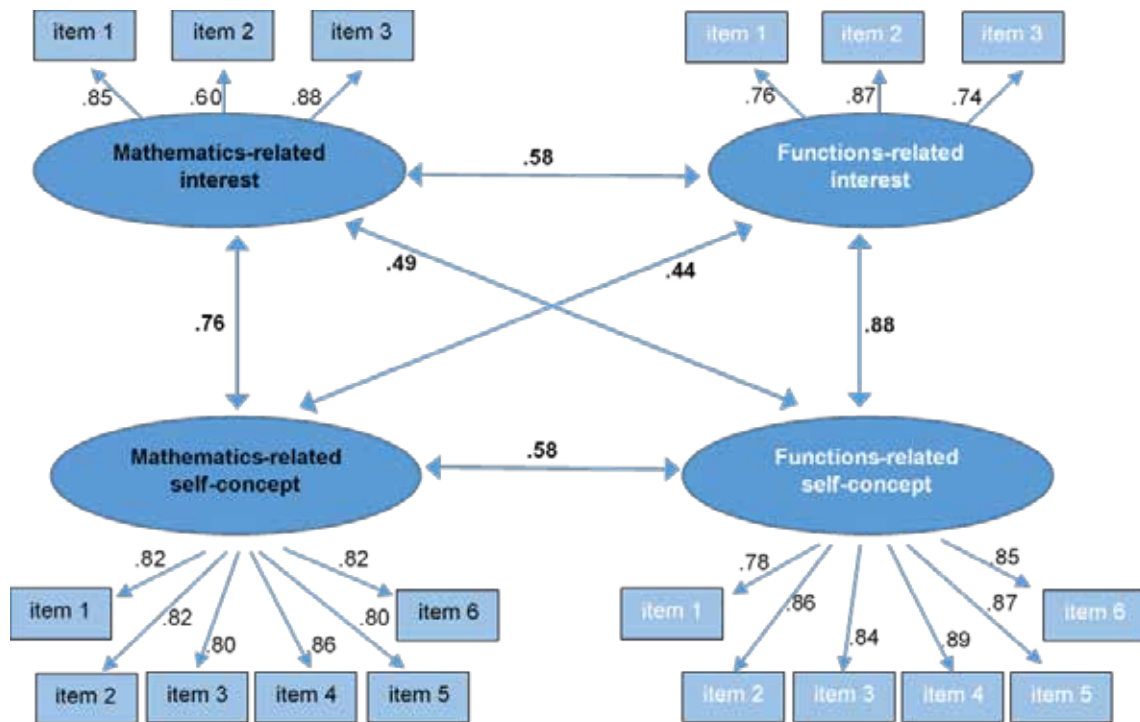

Figure 1: Factorial structure and parameters of Model E (pre-test)

The structure, factor loadings and correlations of the full Model E are displayed in Figure 1 for the pre-test. Similar results were found for the post- and follow-up-test. The rather low factor loading of Item 2 referring to mathematics-related interest is comparable, respectively slightly higher for the post- (.59) and follow-up-test (.63). Analyzing Model E without this item did not lead to better fit indices. Although the four scales mathematics- and functions-related self-concept and interest turned out to be separable, they expose latent correlations of .44 to .88. The correlation between functions-related self-concept and interest is lower for the post- and follow-up-test (both .80).

Table 2 shows Cronbach's alpha in pre-, post- and follow-up-test (fut) for mathematics- and functions-related self-concept and interest ranging from .81 to .94. All in all, the values for the functions-related scales are comparable to the corresponding mathematics-related counterparts.

Construct	Number of items	Sample item	Cronbach's Alpha pre	Cronbach's Alpha post	Cronbach's Alpha fut
Self-concept (mathematics)	6	Understanding mathematics is easy for me.	.92 (N = 811)	.92 (N = 878)	.93 (N = 674)
Interest (mathematics)	3	Doing mathematics is one of my favorite activities.	.82 (N = 831)	.81 (N = 892)	.83 (N = 683)
Self-concept (functions)	6	The domain of functions is easy for me to understand.	.94 (N = 675)	.94 (N = 863)	.94 (N = 677)
Interest (functions)	3	I like best working on functions.	.83 (N = 745)	.88 (N = 895)	.89 (N = 701)

**Table 2: Reliabilities and sample-items of mathematics- and functions-related self-concept and interest**

## Discussion

The purpose of this study is to investigate whether student's self-concept and interest related to mathematics and functions are empirically separable. If students actually perceive mathematics and functions differently with regard to their self-concept and interest, it appears to be reasonable to assess these motivational variables as domain-specific as possible. Doing so is not only recommended by Marsh and Craven (1997) but also enables investigating particular cause-effect-relations of the teacher training under evaluation in the project ProfiL9.

Although single global fit indices show slight deviations from the recommended cutoff values, they all favor the full Model E that differentiates between the four scales mathematics- and functions-related self-concept and interest. This finding is also supported for pre-, post- and follow-up-test by model comparisons based on the adjusted BIC. Moreover, the magnitude of the (significant) factor loadings as well as good values of Cronbach' alpha suggest that the latent variables are reliably measured by the corresponding items. In particular Cronbach's alpha is comparable or even better for the adapted scales than for the established ones. This means that the students of our sample perceive mathematics and functions differently from a motivational point of view and hence that it is reasonable to evaluate self-concept and interest with the adapted functions-related scales. In this sense, we will use these function-related scales in order to investigate particular cause-effect-relations in further analysis steps of our project. Developing and using domain-specific instruments appears to

be applicable also for other studies investigating the effects of domain-specific interventions on motivational variables such as self-concept and interest.

At the pre-test, students were not familiar with functions. Therefore, it could have been assumed that the distinction between mathematics and functions and in particular between functions-related self-concept and interest would not have been perceptible for them (see Model D). However, the factor analysis favors the four-factor Model E already for the pre-test. Hence, students appear to differentiate between these variables even before they participated in the teaching unit of functions.

In any case, latent correlations of about .6 emphasize the relatedness between mathematics and functions. The magnitude of the correlations between self-concept and interest within each domain are in line with the literature and underline the proximity of these variables. The particularly high correlation between functions-related self-concept and interest found in the pre-test decreases in post- and follow-up-test to a level comparable to the mathematics-related counterparts. This is in line with our expectation that at the beginning of the teaching unit of functions students do not differentiate between these variables to the same extent as they do afterwards.

Although the presented results justify the use of the adapted instrument for further analyses such as investigating the development of student's functions-related self-concept and interest, the following limitations should not be disregarded. Some of the global fit indices still show potential for improvement and single factor loadings were lower than they should be. As the scale of mathematics-related interest only contains 3 items and as it proved in other research, we favor to maintain Item 2. However, we will further analyze if a model can be found that provides better fit indices. Concerning future analyses, the instrument will be used to examine how functions-related self-concept and interest develop for students with / without teacher participation in the teacher training mentioned above. In these analyses, covariates such as age or gender will also be introduced in order to monitor the effectiveness of the teacher training in more detail.

*Interventions aimed at fostering students' growth mindsets have been carried out in 21 classrooms (with a focus on Grade 7 and Grade 10) in the Netherlands. The intervention consisted of three main elements: introduction to neuroplasticity, the importance of learning from errors in learning processes, and growth-mindset feedback. Before and after the intervention, the students finished a questionnaire, and during the intervention, students and their teachers were interviewed. Results indicate that the students' mindsets tended to be more towards a growth mindset after the intervention, in particular for the Grade 10 students. Students were very positive about the intervention, especially the neuroplasticity and the attention for and learning from errors. Teachers and students valued the changes in attitudes and interactions with a new language for teaching and learning mathematics.*

*Keywords: Learning motivation, teacher influence, psychology.*

### Introduction

“I don't understand anything” or “What a stupid mistake” are phrases students often say out loud. For teachers, when they pay attention, these words can be an important signal to indicate that students are working with a fixed mindset. Recognition of the mindset by the teacher and explanation of the theory of mindset can help students change their mindset, and by that change their beliefs and attitudes towards mathematics. To influence students' mindset the role of the teacher is indispensable.

### Theory of the mindset

The concepts of fixed and growth mindset were introduced by Carol Dweck (Dweck, 2006; Dweck, Chiu, & Hong, 1995). She distinguished, based on 20 years of research, two types of mindset:

- **FIXED:** you have certain talents, and they remain the same throughout your life.
- **GROWTH:** what you can do or learn now forms the starting point from which you can develop.

Their studies show that the effects of these different mindsets on how students learn are significant, especially in how they deal with challenges and obstacles. When students have a fixed mindset they prefer not to get any challenges. One might think: “Suppose I fail, then people will think I am not very clever, and as this cannot change, I will stay dumb for the rest of my life.” If something goes wrong, and the students have a fixed mindset, then they will feel stuck in a situation to which they cannot change anything. On the other hand, when students are working with a growth mindset then they want challenges. The outcome does not really matter to them; they know and feel that it is

important just to try, that they can learn from their mistakes, that their brains are at work, and that they can change (Boaler, 2016; Dweck, 2006).

The mindset students have is influenced by their upbringing. For example, parents who say “I was never able to do mathematics when I was young” unintentionally influence their children into a fixed mindset. The emphasis on performance in our school systems also plays an important role. High grades and quick results are seen as positive, while they can make students insecure and tend to create a fixed mindset (Dweck, 1995; Dweck, 2006; Mueller & Dweck, 1998). A recent large scale study among undergraduate students showed that their teachers’ mindset beliefs influenced classroom experiences and had a substantial effect on their achievements in STEM fields (Canning, Muenks, Green & Murphy, 2019).

‘Mindset’ is not a trait and it cannot be measured exactly. A mindset may vary with context and over time (Dweck, 2006). However, one’s mindset has an impact on how one approaches and becomes involved in an activity. When students behave according to a fixed mindset while encountering a problem, they are likely to give up quickly and tell themselves: “I will never learn this.” In contrast, when students are working with a growth mindset, they ask themselves “what can I learn from this”, and “how can I try not to make the same mistake too many times.” (Dweck, 2006). For teachers, when they pay attention to the words of their students, these words can be an important signal to indicate that students are working with a fixed or growth mindset. Recognition of the mindset by the teacher and explanation of the theory of mindset can help students change their mindset, and by that change their beliefs and attitudes towards mathematics (Boaler, 2016).

### **Interventions that encourage a growth mindset**

For everybody, students and teachers, it is important to become aware of the impact of their mindset and of its possibilities and challenges (Dweck, 2006). With this awareness, in combination with relatively small social psychological interventions, it has been found that teachers can encourage students to adopt a growth mindset (Yeager & Walton, 2011).

If students believe that they can be smarter and that hard work can help them with this, then they are more willing to exercise (Blackwell, Trzesniewski, & Dweck, 2007). This process has a lot in common with ‘self-efficacy’ that Hattie (2018) is using in his work. Hattie emphasizes the strong correlation between self-efficacy (the confidence that students have in themselves and that can make their learning happen) and student achievement.

Mathematics is eminently a subject where mindset plays an important role. On the one hand, the discipline is highly regarded in our society and it is often associated with something you are good at or not. Good grades for mathematics are seen as a clear proof for being intelligent. And parents compare the results of their children quickly with their own school experience and, unconsciously, emphasize the perspective of being either good or bad in it. Unluckily all these aspects foster a fixed mindset. On the other hand, doing mathematics can give students frustration when they do not see the solution right away. Consequently, working with a growth mindset will help them a lot.

Many ideas for mathematical activities that invite students to develop a growth mindset are provided by Boaler (Boaler, 2016). Some of these interventions, especially the ones that are also described in the studies of Yeager & Walton (2011), Blackwell (2007), and Hattie (2008), have been tested in the school year 2016-2017 at the Goois Lyceum, a secondary school in a small town in the Netherlands.

The evaluation of these tests showed that three main elements of the intervention were easy to implement and were experienced as very valuable: (1) an introduction to the theory of mindset and the importance of neuroplasticity, (2) attention for the importance of learning from errors in the teaching process, and (3) classroom as well as individual growth mindset feedback.

In this study, we investigated to what extent this growth mindset-oriented intervention can improve students' attitude towards mathematics.

## Method

During the school year 2017-2018 the intervention was further developed and implemented in the first grade of secondary school (grade 7) and in upper secondary school mathematics A classes (mainly grade 10). Grade 7 was chosen because these students recently switched to a new school. In upper secondary education, classes with mathematics A were chosen because mathematics A (preparing for humanities) is seen as 'easier' than mathematics B (preparing for natural sciences). These students often feel that they have chosen a 'lower' form of mathematics and that they cannot perform well in this subject. This lower self-efficacy might indicate a fixed mindset, and it is interesting to see whether this can be changed by the interventions. We advertised the possibility to join the project in a newsletter reaching mathematics teachers all over the Netherlands. In total 512 students in 21 classrooms, from nine schools, joined the experiment, of which 383 filled in both the questionnaires.

## Preparation of the teachers

The teachers that were involved in the intervention were given a training of 5 hours at Utrecht University in which the theory of mindset was explained. During the training, teachers got the opportunity to work on some sample activities (low-floor-high-ceiling tasks, Boaler, 2016, or 'My favorite no', Alcalá, 2011) followed by an extensive instruction of the different elements of the intervention. The presentations of the training, the presentations and tasks for the students, and suggestions for further reading were shared online. During the intervention there was a regular exchange of experiences, questions and information through email with the teachers. The intervention contained the following three main elements:

1) Explanation about mindset and the functioning of the brain (neuroplasticity). Although the theory of mindset is a psychological theory it is well supported by brain researchers in relation to the plasticity of the brain (e.g. Woollett & Maguire, 2011; Helden & Bekkering, 2015). Nerve cells, or neurons, can make better and more connections throughout our lives (or loose connections when not in use). This allows a rich distributed dynamic network with many opportunities to learn new things, also referred to as neuroplasticity. Because of this neuroplasticity people have the opportunity to learn and expand their knowledge. It is not just the capacity to learn a new language but also new hobbies and new habits. For example, if you fear failure through training you can learn to become more confident (Hanson, 2009). It is like walking a new path through the jungle; first you need a machete to break through, but after some time when you use the same track more often, a path is created and it gets easier and easier to travel.

At the schools this part of the intervention started with a presentation for all students on the functioning of the brain and on the theory of mindsets. The corresponding task was to make a difficult mathematical assignment without the explanation of new theory. A student with a fixed

mindset would not like this, they avoid starting out of fear of making mistakes. A student with a growth mindset would like to continue, thinking “I’m going to try it” or “If it doesn’t work out I ask it.” The role of the teacher is to give the right growth feedback and to regularly remind students of the neuroplasticity of the brain.

2) The importance of making mistakes and learning from errors. Brains of people who make mistakes with a growth mindset are more active than the brains of someone who makes mistakes with a fixed mindset (Boaler, 2016). When students do not understand the assignment right away and they are thinking with a fixed mindset, they might believe “Now everyone will notice that I am not smart.” They start to get stressed and stress hormones ensure that no new connections between the neurons grow (Dirksen, 2012). Students with a growth mindset will see obstacles more as challenges. They can see that making a mistake is the beginning of learning something new (Chödrön, 2006). They then start to feel more confident which in turn sets the brain in a responsive mode, and this stimulates making new connections in the brain (Hanson, 2009). The teachers are stimulated to use feedback like “I want to understand the way you think and together we can discover what the next step is.”

This intervention started with a presentation about the function of making mistakes and the role of mindset. The teachers started several lessons with “My favorite no” (Alcala, 2011). To change the way in which teachers cope with mistakes is also an aspect of this intervention.

3) The use of feedback. It is important that teachers are aware of the feedback they give, especially while making errors. If they say “what a stupid mistake” they can bring students more towards a fixed mindset. And it is not just the words but also the body language and tones they use. The challenge is to give feedback not on properties or features but on the process (Boaler 2016). It may seem great to hear that you are smart. However, it is a kind of label, leading to overconfidence, or to self-doubt like: yes I am smart now but what if I make a mistake, will they call me dull-brained? (Mueller & Dweck, 1998). When giving feedback on the process it should be true feedback; only when a student has really worked hard one can evaluate this.

It is not just the feedback that students get from others, it is also the feedback they give themselves. In a class, it is helpful to listen carefully to what students say while making the assignments or as they chat. For example, when they say “this is too hard”, this can be associated with a fixed mindset. Whereas when they are saying “this may take some time” this can be associated with a growth mindset.

The attitude of the teacher is important; when a teacher, from a fixed mindset, has the opinion that the performance of the students stays the same throughout the year it might lead to stagnation. On the other hand, when a teacher, from a growth mindset, believes that the performance of the students can grow than students evolve more easily. Good teachers believe in development of intelligence and talent, which is a growth mindset, and they are fascinated by the learning process (Dweck, 2006).

At the start of this intervention on feedback the students were shown a short presentation on feedback, words, and the link to mindset. The assignments they then got were low-floor-high-ceiling tasks, for example “what is the largest surface you can make with 36 piles of 1 meter?”. Students can easily start and while working can make things more and more difficult. The teacher helps them by giving growth and encouraging feedback and challenge them.

To participate in this study teachers were asked – as a minimal requirement – to teach the previously described elements of the intervention (on the plasticity of the brain and the consequences for learning, the importance of errors, and the role of feedback in learning). Furthermore, they were asked to implement at least one growth-mindset task with every intervention. Finally, they were invited to examine their own attitude towards mistakes and to practice with growth-mindset feedback in their classroom.

## Procedure of the intervention

At the start and at the end of the intervention, students filled in a questionnaire to determine their mindset. This questionnaire consisted of 25 statements that were compiled from the literature of Blackwell and Dweck (Blackwell, Trzesniewski, & Dweck, 2007; Dweck, 2006). Students were asked to label their level of agreement to the statements on a 6-point Likert scale. The statements were divided in four types: mindset, effort belief, response to failure, and learning goals. With these different types the impact of the intervention could be measured in different domains. Example questions were:

Q1. You have a certain amount of intelligence and you cannot do much to change it

Q3. An important reason why I do my schoolwork is because I like to learn new things

Q5. It does not matter who you are and where you come from, you can always change your level of intelligence

Q16. If you have to work hard for a subject, you are probably not very good at it.

During the interventions at five schools a lesson with the intervention was observed and students and teachers were interviewed about their experiences.

## Results

In Figure 1 the mean differences in the total score of the questionnaire are represented. It can be seen that in only five classes the total scores after the interventions had lowered, indicating a more fixed mindset. In the remaining sixteen classes the scores went up, indicating a more growth mindset. The Grade 7 classes are drawn in black and Grade 10 in blue, with no clear differences emerging.

**Figure 1. The mean differences in the total scores per class**

In Table 1 the average scores on the different scales are given for the two grades. It can be seen that the effect of the interventions is most clear for the mindset score (e.g. +3.1 for the Mindset scale in Grade 7). Both in Grade 7 and Grade 10 the post intervention mindset scores are higher.

**Table 1: Results of the scores of the pre- and posttest (the questionnaire before and after the mindset interventions); the average of the different grades in the different domains**

(Grade 7 N = 246 Grade 10 N = 137)

Sub scale	Grade level	Pretest		Posttest		Difference
		<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	
Mindset	<i>Grade 7</i>	27.8	6.8	30.9	6.6	+3.1
	<i>Grade 10</i>	27.1	6.2	29.0	7.0	+1.9

Response to failure	<i>Grade 7</i>	38.8	4.9	38.8	5.0	0.0
	<i>Grade 10</i>	37.5	5.4	36.9	5.8	-0.6
	<i>Total</i>	38.4	5.1	38.1	5.3	-0.3
Total score	<i>Grade 7</i>	111.6	12.9	114.2	12.8	+2.6
	<i>Grade 10</i>	106.3	13.2	108.4	14.8	+2.1
	<i>Total</i>	109.7	13.2	112.1	13.8	+2.5

In Table 2 the results of the changes of the individual students show a similar pattern of more pronounced changes in the mindset score compared to the scores in the other domains. Also, here the change towards a more growth mindset is larger in the Grade 7 classes (67.5%). This trend may indicate that the mindsets of the Grade 7 students are more intensely influenced by the interventions.

**Table 2: Results of the changes of the individual students**

Change on	Percentage of changes*	Difference between grade 7 and 10
Total score	39.7% negative change 4.7% no change 55.6% positive change	Grade 7: 38.6% negative, 6.1% =, 55.4% positive Grade 10: 41.6% negative, 2.2% =, 56.2% positive
Mindset score	29.0% negative 7.3% no change 63.7% positive	Grade 7: 26.4% negative, 6.1% =, 67.5% positive Grade 10: 33.6% negative, 9.5% =, 56.9% positive
Learning goals	45.2% negative 14.4% no change 40.4% positive	Grade 7: 49.6% negative, 16.3% =, 34.1% positive Grade 10: 37.2% negative, 10.9% =, 51.8% positive
Believe in effort	39.7% negative 14.6% no change 45.7% positive	Grade 7: 42.7% negative, 12.2% =, 45.1% positive Grade 10: 34.3% negative, 19.0% =, 46.7% positive
Response to failure	45.4% negative 14.1% no change 40.5% positive	Grade 7: 41.9% negative, 15.9% =, 42.3% positive Grade 10: 51.8% negative, 10.9% =, 37.2% positive

\* a negative change is a change towards a fixed mindset; a positive change is a change towards a growth mindset.

All the teachers were very much involved in the intervention. During the interviews they made comments like: “As a mentor, and as a teacher in mathematics, I can now discuss more easily how important it is to learn from your mistakes. I also designate my own mistakes more consciously, and I explain how I deal with them.”

Another teacher writes that she has become more careful with her words. Even small, seemingly unimportant words like quickly (make your assignments quickly) she tries to avoid as it disempowers her lessons. The classes that show a decrease or stability in mindset scores are one Grade 7 class and two Grade 10 classes. Two of these teachers were starting teachers who were very enthusiastic about the intervention but for whom teaching itself was relatively new. The third teacher was a more experienced teacher and also very committed to the interventions. However, in his class there were a lot of changes in the composition of the class, which may have influenced the outcome.

The questionnaire at the end of the intervention included questions about which part of the intervention the students appreciated most. They valued the entire intervention because of its content and also because of the changes in their teacher’s attitudes. The lesson on the brains and on the mistakes were most highly appreciated. One student explained: “I have to stop thinking ‘this will cost too much time’, or ‘I really cannot do this’; instead I can persevere or try again later.”

The personal interviews with students also revealed that the lesson on making mistakes was experienced as the most positive, though also after the interventions one student made the following remark: “I did learn that making mistakes does not matter, however I still do not like it.”

Students and teachers reported during the interviews that an important element of working with mindset is the use of words. One student noticed “It sometimes seems as if we have learned a new language together.” Another student said “Sir, this feels like a fixed remark, do you mean it like that?” One teacher said: “I find it a real challenge, you have to pay attention to all the words the students are saying, also the words they say to each other and to themselves. To be able to do that of all the students is not (yet) possible, however with a few students separately I do succeed.”

## Discussion

The mindset theory addresses issues that are highly relevant for current teaching practices in mathematics education. We are aware that changing teachers’ teaching and students’ learning behavior can hardly be achieved through a one-day training for teachers. Nevertheless, this study shows that teachers did become sensitive for changing their practice towards fostering a growth mindset after a training of only five hours and some initial experiences with the interventions. From this study, the effects of changing practices on student achievements are not clear. What it does show is an obvious attitude change towards students’ own learning and towards the importance of making mistakes in learning mathematics. These are important first steps towards a changing culture in the mathematics classrooms. Finally, teachers reported that the mindset theory provides an inspirational vocabulary and set of tools to implement and improve daily teaching practices.

The training of teachers was first seen as a preparation for the three elements of the intervention mentioned above, but actually it turned out to be a separate intervention. Once teachers were familiar with the theory of the mindset they changed their lessons: teachers were more aware of the mindset from which they taught their students, of the importance of learning from their mistakes and the feedback they gave. And this had a direct impact on the mindset of their students.

## Acknowledgments

We would like to acknowledge all the students and teachers that have worked with the interventions. We have learned so much from all of you. Thanks for being so open to all new ideas. Also thanks to everyone from The Goois Lyceum, for being experimental subject in this study.

# Low achiever's mathematical thinking: The case study of Maya

Hanna Viitala

Luleå University of Technology, Sweden; [hanna.viitala.edu@gmail.com](mailto:hanna.viitala.edu@gmail.com)

*In this paper, one low achiever's, Maya's, mathematical thinking is reported. Mathematical thinking is studied through problem solving and view of mathematics. The results indicate that Maya has severe gaps in mathematical knowledge and problem solving. Furthermore, affect hinders her learning and activities in mathematics. Despite the challenges, Maya wants to learn mathematics and succeeds in giving an answer to every mathematical problem in the study. In addition to further support in mathematics and affect, she could benefit from learning to use different representations in mathematics and picturing the tasks in real life.*

*Keywords: View of mathematics, problem solving, metacognition, affect, meta-affect.*

## Introduction

Finnish pupils' success in mathematics has been acknowledged in international studies such as PISA and TIMSS (see e.g. Välijärvi, 2014) and national assessments show that Finnish pupils' performance is at a satisfactory level (e.g. Hirvonen, 2012). However, the most recent studies indicate that Finnish pupils' performance is descending (ibid.; Rautopuro, 2013), showing also the diminishing number of high achievers and the growing share of low achievers in Finland (Kupari & Nissinen, 2015). Furthermore, pupils' affect towards mathematics is alarmingly low at the end of lower secondary school (Tuohilampi & Hannula, 2013).

To understand the recent development, we need to know more about Finnish pupils' mathematical thinking. What is it like at the end of comprehensive school? Previously, Viitala (2017a) has reported on four Finnish high achieving pupils' mathematical thinking. These pupils all liked mathematics, were successful problem solvers and enjoyed learning mathematics. However, a deeper look into their problem solving and view of mathematics revealed very different skills and competences in mathematics. Nevertheless, whatever their strengths and weaknesses were, their strengths compensated their weaknesses in mathematics. How is the situation different with low achievers? What is it that separates low achievers from high achievers? In addition to differences in mathematical knowledge, what might be the possible reasons for the low performance in mathematics?

In this paper, one low achiever's, Maya's, mathematical thinking is reported. The data is collected through problem solving and view of mathematics. The purpose is to study Maya's strengths and weaknesses in mathematics that go beyond her mathematical knowledge. The purpose is to answer the question 'What characterizes Maya's mathematical thinking at the end of lower secondary school?'

## Theoretical framework

Following the recent theories on affect, mathematical thinking can be viewed through two temporally different aspects; state and trait (cf. Hannula, 2011; 2012). While thinking is always situational and contextual, a state, it is also influenced by more stable constructs such as beliefs and attitudes, traits (cf. ibid.). These two temporally different sources of data together can reveal the dynamic and

complex thinking processes that pupils go through while thinking mathematically (for an example, see e.g. Viitala, 2017b).

In this study, the state aspect is studied through problem solving. The pupils' actions and explanations during problem solving are interpreted as visible signs and expressions of their mathematical thinking. In addition to the mathematical knowledge and heuristics in problem solving, pupils' problem-solving behaviour is influenced by their metacognition, affect and meta-affect that occur in a problem-solving situation (cf. Schoenfeld, 1992).

The successful application of problem-solving activities at the correct moment is a result of metacognitive skilfulness (e.g. Schoenfeld, 1987; Flavell, 1979). These skills include for instance monitoring one's actions and directing resources in a problem-solving situation (Schoenfeld, 1987). Affective state influences problem-solving activities for instance through the feeling of confidence, and meta-affect transforms individuals' feelings (DeBellis & Goldin, 2006) directing pupils' problem-solving behaviour (Carlson & Bloom, 2005).

Problem-solving processes can show patterns of thought that can be interpreted as signs of more stable ways of thinking. These patterns, together with pupils' view of mathematics, represent the traits in this study. Pupils' view of mathematics is studied through five components: mathematics as a science and as a school subject, oneself as a learner and user of mathematics, learning mathematics, teaching mathematics (Pehkonen, 1995), and view of mathematical thinking.

The structure of pupils' view of mathematics is derived from belief-research that has traditionally been studied as traits (see e.g. Op't Eynde, de Corte, & Verschaffel, 2002). However, in separation from many earlier studies, in this study pupils' view of mathematics is considered as psychological phenomenon that is a mixture of cognitive, motivational and emotional processes (Hannula, 2011; 2012). In addition to beliefs, these processes include also for instance attitudes, values, feelings and motivation (ibid.; thus the word 'view', see Rösken, Hannula, & Pehkonen, 2011).

## **Methods**

### **Data collection**

At the time of data collection, Maya was 15 years old. She was in 9th and final year of Finnish comprehensive school. She was a low achiever in mathematics (mathematics grades between 5 and 6 on a whole number scale of 4 to 10).

The data was collected in three cycles over the course of three months. In each cycle, 1-2 mathematical problems (PISA tasks) were solved in an ordinary classroom situation. In class, Maya solved the tasks individually, but she could talk about the tasks with her friends and ask help from the teacher. In the third cycle, Maya was absent from class and solved the problems in the interview. Maya was video recorded while she solved the tasks and her solutions on paper were collected.

Here is an example of a PISA task used in data collection: 'This problem is about planning the best route for a holiday. Figures A and B show a map of the area and the distances between towns [in a table]. [...] Calculate the shortest distance by road between Nuben and Kado.' (OECD, 2006, pp. 77-78; for a part of the task, see also Figure 1).

Maya was interviewed three times, on the same day or on the next day after each of the problem-solving lessons. The interviews were semi-structured and contained two parts. The first part concentrated on Maya's view of mathematics. It followed the categorisation introduced in theoretical framework: background, mathematics as a school subject and as a science, oneself as a learner of mathematics, learning mathematics, teaching mathematics (following Pehkonen, 1995; cf. Op't Eynde et al., 2002), and view of mathematical thinking (for example questions, see Table 1).

Theme	Example question
Background	Tell me about your family.
Mathematics	Does mathematics exist outside of school? Where?
Oneself and mathematics	Is mathematics important to you?
Mathematics learning	How do you learn mathematics?
Teaching mathematics	Does teaching matter to your learning? How?
View of mathematical thinking	How do you recognise mathematical thinking?

**Table 1: Interview themes and example questions**

The second part concentrated on problem solving. The data from class was used as stimuli when Maya's problem-solving processes were discussed. She was asked to explain her thinking and actions during the problem-solving situation. Also supporting questions were asked (e.g. What are you thinking now? Why are you doing so?).

Finally, in each of the three interviews, Maya was asked to assess her confidence before, during and after solving the problems, as well as to assess her confidence in school mathematics using a 10 cm line segment (scale from 'I couldn't do it at all' to 'I could do it perfectly'). All interviews were video recorded.

### **Data analysis**

The analysis was divided into two sections: problem solving (state) and view of mathematics (trait). First, problem-solving processes were analysed through four problem-solving phases: orienting, planning, executing and checking (Carlson & Bloom, 2005). Then, the results were complemented with the metacognitive activities of orienting, planning, evaluating and elaborating (see examples in van der Stel, Veenman, Deelen, & Haenen, 2010), affect (cognitive, emotional and motivational states and traits; Hannula, 2011; 2012) and meta-affect (DeBellis & Goldin, 2006) emerging in the problem-solving processes. Finally, Maya's confidence to solve the problems were analysed.

Second, Maya's view of mathematics was analysed following the themes of data collection (Pehkonen, 1995). After data condensation, a pupil profile was created. Pupil profile is a short description of the pupil that is used as background information. It is based on Maya's mathematics grade, motivation to learn mathematics, and ability, success, difficulty, and enjoyment of mathematics also known as the core of herself as a learner of mathematics (Rösken et al., 2011).

In the end, the results from problem solving (state) and view of mathematics (trait) were compared and combined to get a holistic view of Maya's mathematical thinking.

## Results

Pupil profile: Maya is a low-achieving, very unsure and quite anxious mathematics learner. She does not value mathematics as important, but would still like to learn it. Her low level of mathematical knowledge and skills go hand in hand with her low level of affect and meta-affective skills in mathematics.

The most prominent result of the study is the low level of affect that Maya has in and towards mathematics. When we begin discussing about mathematics, Maya starts by saying that she is very bad at mathematics, has always been. She then continues to express her low level of affect throughout the study: She explains that she has no idea what mathematics is as a science because she is very bad at mathematics; Mathematics is not important because she does not really know mathematics; She does not feel confident in mathematics; She feels anxious in mathematics classes and especially so in tests; She feels that she has never succeeded in a mathematics test; Or simply, mathematics is too difficult for her.

Maya has great difficulties also in solving problems. She felt stressed in problem-solving situations and the tasks felt difficult. Before she could start solving the problems, she needed confirmation from the teacher (or from the researcher in the interviews) that she had understood the problem correctly. Unfortunately, Maya is not initiative in asking help in class. She feels afraid of making mistakes, she

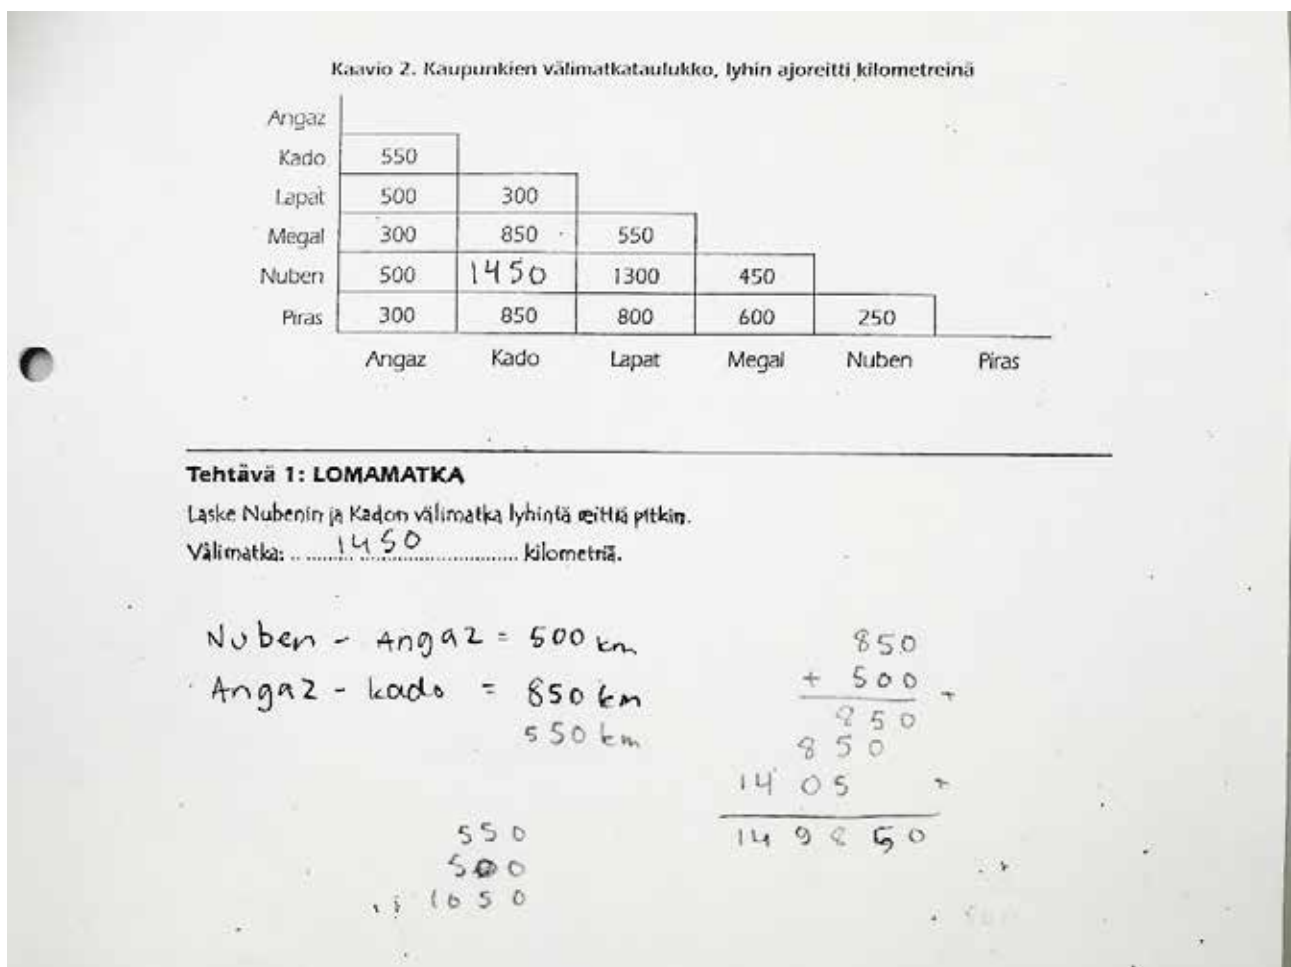

Figure 1: A partial caption of the task 'Holiday' (OECD, 2006, p. 77) and Maya's interview notes

is afraid that the teacher asks questions or gives critique, and she is afraid that her classmates notice her problems. This mismatch between the need for help and not asking for it, and consequently staying stuck, is just one example of the low level of meta-affective skills that Maya has in mathematics. Fortunately, though, when the teacher approaches her, she usually gets the help she needs to continue with the problem.

In addition to the low affect and meta-affective skills in mathematics, Maya's mathematical skills are quite limited. For example, in the problem introduced above, Maya had difficulties in reading the table and in adding. First, she did not understand what the numbers in the table represent before the teacher explained the table to her. Even then, she took the distances she needed from the first cell next to the town names (500 next to Nuben and 850 above Kado; see Figure 1). Maya explained that she did not understand the table until the interview.

After getting the distances she needed from the table, Maya had to add the numbers together. She explained that she could not add the numbers (500 and 850) mentally, so she calculated them on paper (for a reproduction of the calculation, see Figure 1). Maya's calculation was a mixture of adding and multiplying rules and the result was incorrect. In the interview, Maya explained that she took the first and last two numbers as the result and ignored the third and fourth numbers. Even though the method seems absurd, there is something positive: she had a realistic view of the magnitude of the answer.

There are severe problems in Maya's knowledge base and affect. Metacognitive actions are almost non-existent, also meta-affective actions, and she needs very much and very concrete help to solve the problems. However, there too is something positive: She does want to learn mathematics. She recognizes that for her own learning, she needs to follow teaching in mathematics classes and ask questions. She has noticed that when the teacher relates new knowledge to old knowledge, it helps her to learn mathematics. Even though she has emotional obstacles in communicating with her teacher, she seeks and gets more mathematical help from their special needs teacher. She emphasizes the importance of doing homework alone and undisturbed. And, she recognizes that she needs mathematics in future studies and jobs.

In mathematics learning, Maya needs help in developing her conceptual and procedural skills, and support to overcome many emotional issues. However, in connection to problem solving, there is one concrete thing that rose above other issues. When Maya got stuck in problem solving, she understood the problem best with a new representation. Moving the task to real life or drawing a picture was enough to help Maya to understand the problem. Moving between different representations in mathematics could help her to improve her problem-solving skills and her conceptual knowledge.

## Discussion

This paper aimed at answering the question 'What characterizes Maya's mathematical thinking at the end of lower secondary school?' Maya is best characterized through the low level of mathematical knowledge and skills, and through the low level of affect towards mathematics. More specifically, the very negative view of herself in mathematics seem to hinder her learning and solving mathematical problems. This negative trait connected with the negative state reactions to the problems and problem-solving situations, as well as nearly non-existent meta-affective skills, almost

prevented her to solve the problems in the study. The low level of mathematical and metacognitive skills support the situation.

In addition to the low level of mathematical knowledge, the low level of meta-affective and metacognitive skills seem to be what separates Maya most from the high-achieving students in the research project (see the high-achieving students' results in Viitala, 2017a). Being unsure and having negative affect towards mathematics are features that students in all achievement levels experience. In fact, the most recent national studies show that Finnish pupils' affect towards mathematics is unnecessary negative at the end of comprehensive school (Tuohilampi & Hannula, 2013; Hirvonen, 2012). However, while Maya seem to paralyse when experiencing difficulties in solving mathematical tasks, the high-achievers use their meta-affective and metacognitive skills to overcome them (see e.g. Viitala, 2017a). What all students in the research project have in common, though, is the positive feeling they get when they succeed in mathematics, and the will to learn mathematics, on their own levels and on their own terms.

The national studies also show that pupils start school with positive attitudes, but their attitudes towards mathematics as well as self-efficacy beliefs decrease consistently throughout comprehensive school, and pupils' anxiety in mathematics increase in lower secondary school (Tuohilampi & Hannula, 2013; Metsämuuronen & Tuohilampi, 2014). Maya's affect fits well with the results of Finnish large-scale studies at the end of comprehensive school. However, the results indicate that the situation has not been positive even at the beginning of her school years. For instance, Maya states that she has always been bad at mathematics and she cannot remember ever succeeding in a mathematics test. Having a different mathematics teacher in every grade might also been a factor in Maya's learning of mathematics: While Maya is shy and very unsure of herself in mathematics, it takes time for the teacher to get to know her thinking so that the teacher could have the best tools to help Maya to develop mathematically.

So, what can be done to help pupils like Maya first to create and then to maintain more positive attitude towards mathematics, and to build mathematical knowledge and skills at their own rate? One solution could be to increase the amount of problem solving in mathematics classes. Even one monthly problem-solving lesson has shown to slow down the decreasing trend in girls' attitudes towards mathematics (Tuohilampi, Näveri, & Laine, 2015). Problem solving is also an effective tool for the teacher to learn about pupils' mathematical knowledge and thinking. Additionally, referring to real-life situation helped Maya to solve problems. Problem solving and applying mathematics to real-life situations are written as learning goals also in the Finnish curriculum (see FNBE, 2014).

One way of supporting Maya's growth in mathematics could also be setting long-term goals for her learning. In Maya's case, the long-term goal could be referring to real life and learning to use different representations in mathematics and problem solving (cf. Heinze, Star, & Verschaffel, 2009). Setting and evaluating the long-term goals in learning discussions, using written self-evaluation and supporting the development through formative assessment in mathematics classes, have shown promising results for students learning in a small pilot study implemented during spring semester 2018 (see more in Viitala, 2018). However, how and if these activities help pupils in a longer period of time, is a matter of a long-term continuation study with a larger number of pupils.

*In this paper, we describe the impact of a mathematics game programming project on the intrinsic motivation of eighth grade students ( $n = 8$ ). We investigate which aspects of the project contributed to student motivation based on a taxonomy that distinguishes individual (e.g., challenge) and interpersonal motivation aspects (e.g., recognition). We also employ these aspects to compare the programming project to regular mathematics education. The findings reveal that students appreciated the project because it was challenging and they had freedom of choice. All group members had a positive attitude towards learning. In regular mathematics classes, they experienced a lack of challenge while the freedom of choice was minimal.*

*Keywords: Intrinsic motivation, autonomy, mathematics education, programming.*

## Introduction

To foster intrinsic motivation, a learning environment needs to respond to students' needs for autonomy, feeling of competence, and social belonging (Ryan & Deci, 2000). A key question in secondary mathematics education is: what can teachers and educators do to create such an environment? As the motivation<sup>1</sup> for mathematics decreases during secondary school (OECD, 2013), we need to find ways to make educational practice more motivating.

The need for autonomy is especially complicated to promote in a formal learning context. Autonomy can be supported by anticipating students' intrinsic values and interests and by creating a context in which they feel at the root of their own learning behavior. This is diametrically opposed to the situation in mathematics education in many countries including our own, where educational practice is strongly guided by textbooks and national examinations.

The research question addressed in this paper is: how can aspects of a formal learning environment in which students' autonomy is supported contribute to an increase of the intrinsic motivation of students with a positive attitude towards learning? We describe the results of an intervention in which such an environment has been developed in the form of a mathematics game programming project for eighth graders. The learning goal was two-fold: while the main goal was to learn programming, as a secondary goal the project also aimed to extend students' mathematical knowledge. Since joining the project was on a voluntary basis, the eight participants were all motivated at the beginning of the project. Following them for a period of nine months and interviewing them at the end of this period gave us the opportunity to analyze what kept them motivated. The results of this study provide insights into the potential of giving (supervised) autonomy and a challenging task to students that are willing to learn.

---

<sup>1</sup> In the remainder of this paper, when we speak of 'motivation', we mean 'intrinsic motivation'

## Theoretical framework

Research has delivered opposite findings with respect to the possible gain of playing computer games in education. Whereas several researchers measured a positive impact on problem solving capacities, no consensus has been reached with respect to the influence on motivation and attitudes towards mathematics (Kebritchi, Hirumi, & Bai, 2010; Perrotta, Featherstone, Aston, & Houghton, 2013; Wouters, Van Nimwegen, Van Oostendorp, & Van der Spek, 2013; Wouters, & Van Oostendorp, 2017). Wouters et al. (2013) came up with three reasons for the lack of improvement of students' motivation: they had limited autonomy, the connection between game design (focus on entertainment) and instructional design (focus on learning) is not natural, and the instruments used to measure motivation may not be appropriate.

Although research has been conducted on the potential of playing computer games in education (student as consumer), the potential of letting students develop and create such games (student as producer) has been explored insufficiently. Ke (2014) concluded after a six-week experiment using the *Scratch* programming environment that developing games stimulated the process of mathematical thinking and gave students a more positive attitude towards mathematics. He did not investigate why students' attitudes improved.

Intrinsic motivation is a multi-faceted concept that can be investigated from different perspectives. Self-determination theory (SDT) takes the learners' needs as a starting point and states that a motivational environment supports the needs for autonomy, feeling of competence, and social belonging (Ryan & Deci, 2000). The ARCS model of motivational design distinguishes four steps of promoting and sustaining motivation in the learning process: attention, relevance, confidence, and satisfaction (Keller, 2009). According to Malone and Lepper's (1987) model based on what makes gaming fun, motivation can be supported at the individual level (challenge, curiosity, control, and fantasy) and at the interpersonal level (cooperation, competition, and recognition). Elements that threaten to reduce students' intrinsic motivation are tangible rewards, threats of punishment, time pressure, and overly close surveillance (Ryan & Deci, 2009). The exploratory study described in this paper focuses on the impact of creating mathematical games on student motivation on the basis of Malone and Lepper's model and contrasts the programming project with regular mathematics education. The project was based on a constructionist approach to education (Papert & Harel, 1991): students learned through creative making processes and discovered the necessary knowledge themselves instead of receiving it passively.

## Methods

The design of the programming project was driven by students' need for autonomy. During the first phase, they learned the basics of the *Processing* programming language, and all had to do the same assignments. This phase ended with the design and creation of a simple computer game. The second phase started with an advanced programming course. As the students' skills developed, their level of autonomy increased, which also meant that they got more freedom. In the final assignment, they designed and created their second computer game, with the only requirement that their game included a mathematical element (in the topic and/or in the code).

This assignment required many skills from students: they had to be creative (mathematical topic, design, rules, goals), to estimate their level of competence, to acquire new skills (mathematical and programming), and to manage their own process. The mathematical knowledge they acquired differed depending on their game.

Eight students (aged 13–14, grade 8) took part in the programming project, which was organized as an extracurricular activity open for all eighth graders in the school pursuing junior university preparatory education (VWO, 171 students) or junior general secondary education (HAVO, 94 students). Twelve students started in the project, but four of them withdrew after completing the introductory course due to health problems (1), a lack of interest (1), or school results (2). This paper focuses on the eight remaining students, who all pursued junior university preparatory education. They had in common that they were all motivated to learn programming, while they differed in intelligence, diligence with respect to schoolwork and math interests. Three of them had been diagnosed as gifted students of various types (Neihart & Betts, 2010): type 1 (opts for safe route), type 5 (demonstrates inconsistent work), and type 6 (autonomous learner). For the statistical analysis, the students who dropped out have been included in the test group.

Since the programming project was a long-term, extracurricular project, random selection of participants was not possible. As a consequence, we were not able to compose a control group that was similar to the test group. To position the participants within their cohort of eighth graders ('comparison group',  $n = 171$ ), they all completed the *Attitude towards Math Inventory* (ATMI) questionnaire before and after the project, which consists of 40 five-point Likert-scale items on attitudes towards mathematics related to self-confidence, value, enjoyment, and motivation (Tapia & Marsh, 2004). For this research, the motivation scale (5 items;  $\alpha = .793$  (pre-test),  $\alpha = .803$  (post-test)) is especially relevant. The scores on mathematics tests in grade 8 have been collected for all students from the test and comparison groups as well.

Before joining the project, students were asked to write a motivation letter. At the end of the project, they completed a questionnaire covering several themes: (1) their motivation for programming, (2) the learning outcomes, (3) the transfer from programming to mathematics, (4) a comparison between the programming project and regular classes, and (5) the supervision during the project. Their answers to the questions were the starting point for semi-structured individual video-recorded interviews. We analyzed the motivation letters and interviews to identify students' reasons for joining the programming project and the factors of the learning environment within the project that contributed to the students' motivation using the categories distinguished by Malone and Lepper (1987) as a frame of reference: challenge, curiosity, control, cooperation and recognition. Fantasy and competition have been left out, since these were not relevant in this intervention. In addition, the interviews were analyzed to find out what lessons can be learned from the project for traditional mathematics class in grade 8.

## Results

### Preliminary analysis

As could be expected on the basis of students' voluntary participation and preference for STEM subjects, the score on the ATMI motivation scale was significantly higher in the programming

( $M = 3.58$ ,  $SD = 0.48$ ) than in the non-programming ( $M = 2.66$ ,  $SD = 0.71$ ) group ( $t(159) = 4.05$ ,  $p < .001$ , effect size Hedges'  $g = 1.32$ ). This was still the case after the project ended ( $t(155) = 3.16$ ,  $p = .002$ ,  $g = 0.99$ ).

### **Students' intentions**

The students' reasons for joining the project as described in the motivation letters can be summarized into four types, all of them related to cognitive curiosity. The first and most common reason concerned preparation for their future. They had a preference for STEM subjects in school and considered a programming job in the future as a likely option. As a second reason, students liked the challenge of learning something completely new. Third, some students who had already been introduced to programming wanted to deepen their skills. They did not manage to learn programming on their own, either because the learning materials were not suitable or because they missed support and guidance. As a last reason, one of the students wanted to learn programming, because the possibilities with respect to programs that can be coded are limitless. In the interviews, the eight students indicated that the project lived up to their expectations: it was more challenging, the assignments were more open, and they learned more than expected. The results are described in more detail below on the basis of Malone and Lepper's (1987) motivation taxonomy.

### **Individual motivation**

#### *Challenge*

Providing an optimal level of difficulty for learners is important for motivation (Malone & Lepper, 1987). During the project, it went too fast or was too complicated for some students at the beginning of the introductory course and at the beginning of the advanced course. Despite the level of difficulty being too high during these moments, the eight participants did not withdraw. Their reasons to persevere were diverse: practical ("waste to stop after investing so much time"), social ("nice group"), and personal ("want to be proud of own accomplishment").

At the end of both phases, in which students designed and built their own games, the difficulty level was adapted to the skills of the student in a natural way, which made it challenging for everyone. The outcome was uncertain, as they did not know in advance whether they would manage to implement all their plans. They were creating something completely new that had not been created in the same way by others before. The students challenged themselves to make the best games possible and acquired additional skills when needed, both at the programming and at the mathematical level (e.g., gravity, radians). Both the weaker and stronger programmers appreciated that they were able to work at their own pace and difficulty level.

A challenging learning environment provides learners with structure in the form of short-term and long-term goals. This was the case in the programming project as well. During the learning phases, weekly short-time goals had to be accomplished. The final assignment (creating a math game) was split into some smaller short-term goals as well. For example, the students were not allowed to start programming before tutors approved their idea on paper. Although the students got frustrated when they did not get the green light directly, they were aware that the detailed

plan helped them during the rest of the development process. In this phase, the students also had to set their own goals, because all of the games were different and required their own planning.

Performance feedback helps to keep students motivated (Malone & Lepper, 1987). An advantage of programming is that some basic feedback is provided directly by the computer: does the game do what I want it to do? However, when a program does *not* work properly, it is often difficult to understand what is going wrong, and therefore human feedback is useful as well. The small group size, the weekly sessions, and the availability of the WhatsApp group enabled prompt performance feedback. The feedback was always constructive and if an explanation was not immediately clear, students kept asking until their problem was solved. Tutors and peers promoted the self-esteem of the students during class as well as during group presentations.

Whereas the programming project was challenging for all students, this was not the case with their mathematics classes. When it comes to giving feedback, programming was considered superior to mathematics as well. The direct feedback provided ‘for free’ in programming (e.g., error messages, output on the screen, behavior of the game) is not available when making mathematics homework where it requires effort from students to receive feedback.

### *Curiosity*

Cognitive curiosity was one of the motives for students to participate in the project. Some of them had basic programming knowledge and wanted to learn more while others had no experience at all. When such curiosity and eagerness to learn something new is not present at the start, it will be more complicated to get students involved. Despite the absence of formative tests, students stayed actively involved and were willing to invest time and effort to achieve their learning goals because of their cognitive curiosity. According to one of the students, cognitive curiosity is not always stimulated properly in math class. Their teachers explain everything instead of promoting inquiry-based learning.

### *Control*

According to Malone and Lepper (1987), having influence on your own learning process is a prerequisite for being motivated. All students appreciated the fact that they had the opportunity to follow their own paths in the introductory and the final assignment. Only one of the students indicated that the assignments could have been even more open (not restricted to games). The final assignment, where the students got several months to create their own math game, especially promoted their feelings of autonomy. It gave them a sense of power to be able to create their own game:

*I really liked programming. It was problem solving, which took a great deal of time and when I then succeeded, it made me happy: “Yes, I finally did it”.*

The final assignment created a highly responsive learning environment, where students and tutors were continuously interacting on how to proceed. Even during holidays and weekends, questions were being asked and answered in the project WhatsApp group.

In the video-interviews and on the questionnaire all students (strongly) agreed that they got enough freedom to work on their own plans. One of them explained why he enjoyed the level of

freedom in the project over the common practice at school: in the programming project he could use his own imagination and creativity instead of “following a cookbook recipe”.

## **Interpersonal motivation**

### *Cooperation*

Although programming is partly a lonely activity, the programming project incorporated cooperation between students at several levels as well. The first way in which cooperation was ensured was the level of instruction. Instead of a teacher being in charge, peers who were only three years older (‘tutors’) gave the lessons and guided the students’ projects. This peer-to-peer structure made the setting more informal and lowered the threshold for students, especially when they needed help outside of the classroom. As a second way of promoting cooperation, there were no classroom rules with respect to seating, walking around or talking. Throughout the project, the students got to know each other and they got more and more involved in each other’s games. They also started to help each other and shared ideas. The third cooperation mechanism was the WhatsApp group, where students shared their questions with their peers. Students who asked more questions during class were also more active in the app group, both in asking and answering questions. The tutors did not always provide ready-to-use solutions, but asked questions and gave suggestions to stimulate students to come up with their own solutions.

Cooperating on school tasks was not common for these students during class. The reasons given for their difference in behavior between the programming project and regular classes are the lack of challenge and social pressure in their regular classes.

### *Recognition*

The students developed real games that could be played by others and their efforts were clearly appreciated by their surroundings. They were given the chance to present both their games once they were (almost) finished. The first presentation marked the transition of the introductory course to the advanced course. Their parents and siblings were invited at school for this presentation, where the students also received a certificate. They presented their games, but there was also time to try and play all games. The second presentation was given at the end of the project. The students sometimes showed their games to their friends and got recognition from them as well for their efforts.

## **Discussion and conclusions**

The question to be answered was how aspects of a formal learning environment in which students’ autonomy is supported contributed to an increase of the intrinsic motivation of students that have a positive attitude towards learning. Malone and Lepper’s (1987) taxonomy provided an appropriate framework for understanding what happened during the intervention. Although the number of participants was small and the outcomes could not be compared with a control group, we have reasons to believe that providing autonomy indeed had positive consequences for many motivational aspects, both at the individual (challenge, curiosity, and control) and the interpersonal (cooperation, recognition) level. Most importantly, compared to traditional mathematics classes, the learning process became more challenging, because students were

allowed to set their own goals and could make their games as complicated as they wanted. Focusing on the need for autonomy directly affected the needs for feeling competent and social belonging as well (Ryan & Deci, 2010). Integrating autonomy with guidance and support increased students' feelings of competence and thus the motivation potential. In addition, the autonomy to choose their own level of difficulty allowed all students to feel competent. The need for social belonging was unintentionally met: the eight students coming from five different classes developed a pleasant working atmosphere together, which increased their motivation to proceed and persevere even when they found it difficult.

As a follow-up of this project, it would be interesting to implement the motivational aspects from the programming project in a regular class, including students with less positive attitudes towards learning. Another question for future research is whether focusing on the need for autonomy in regular mathematics classes could also strengthen students' feelings of competence and social belonging. The current attention for problem solving in mathematics education in the Netherlands (Doorman et al., 2007) is a promising step in this direction, because this provides opportunities for responding to students' need for autonomy. Lessons learned from our intervention are that it is important to make problems as open as possible allowing students to use their own creativity and to make them understand why problem-solving skills are relevant.

The focus of the current study was on the impact of autonomy on motivation. Another aspect that could be analyzed would be the influence of such a programming project on the students' creative thinking skills and their mathematical knowledge. The students indicated in the interviews that the programming project was more challenging and more interesting than their mathematics classes. Although the participants' motivation for mathematics was higher in the current study, they did not outperform their peers with respect to mathematics test scores before the project started. The learning outcomes with respect to mathematics have not been analyzed in detail in this study.

The way in which the programming project was organized shares characteristics with the Maker Movement, a community of hobbyists, engineers, hackers, and artists that builds on each person's ability to create things (Martin, 2015). The movement did not start in education, but educators are becoming interested in adopting the *making* activity into secondary education to enhance opportunities for students to engage in STEM practices. The Maker Movement makes learning more tangible and less abstract. The programming project has shown that this motivates students and that it makes them proud if they manage to create something they designed themselves. As a follow-up of the programming project, the eight project participants decided to participate in a national competition in which they are going to program a robot (the micro:bit).

# **“I want a high-educated job that pays well and is fun”: Secondary students’ relevance beliefs for taking advanced mathematics**

Anders Wiik and Pauline Vos

Faculty of Science and Engineering, University of Agder, Norway

[anders.wiik@uia.no](mailto:anders.wiik@uia.no), [pauline.vos@uia.no](mailto:pauline.vos@uia.no)

*Many students experience the content of the mathematics classroom irrelevant to their lives. At the same time, achievement in mathematics is widely regarded as an important part of general education. In this paper, we report on a study regarding students’ relevance beliefs. For this, we network Engeström’s cultural-historical activity theory with Skovsmose’s theory on foregrounds, and introduce the terms ‘realized’ and ‘emergent’ activity systems. Students provided a wide variety of beliefs, in which the belief of mathematics as door opener to higher education and key to options in life was leading. The belief in the exchange-value of mathematics overshadowed beliefs on the use-value of school mathematics (for other school subjects, for undefined jobs or for mental training). We recommend teachers and textbook authors to include more information on the relevance of mathematics in future studies and jobs.*

*Keywords: Beliefs, exchange-value (of mathematics), cultural-historical activity theory, emergent activity systems, relevance (of mathematics).*

## **Introduction**

Many teachers of mathematics encounter the question “*why do we need to learn this?*”. While sitting in the mathematics classroom, listening to the teacher, doing tasks and tests, many students find little relevance in the mathematical activities they are made to engage in (Bishop, 1988; Onion, 2004). Rather than learning about the usefulness of mathematics or using mathematics to solve authentic problems from out-of-school contexts, the students learn that mathematics is about mathematical objects (numbers, triangles,  $x$ , etc.), and that they must find an appropriate procedure to reach a correct answer (and only one) within a short time frame (Dowling, 2002).

The finding that students ask this ‘why?’ question has been consistent for several decades. It opens a range of questions: why is it that many students find school mathematics irrelevant, how can mathematics teachers convey relevance, can mathematical modelling improve students’ experiences of relevance, do experiences of relevance influence performances, and so forth. We cannot cover all these issues. In the present study we focus on students and their reasons for engaging in advanced mathematics; if they chose that path, then they must somehow see it as relevant.

Students’ reasons for engaging in advanced mathematics are part of their belief system. Students have beliefs about themselves, about the school, about their peers, about life, and so forth. According to Skott (2014), beliefs are mental constructs that are subjectively true for the person in question, beliefs are considered relatively stable, and beliefs affect the person’s interpretations of experiences.

Following Hernandez-Martinez and Vos (2018), relevance is a connection between (1) a person’s subjective perception, (2) an activity by the same or another person, (3) an objective (an aim), and

(4) a value. In the present study, we consider *relevance beliefs* as a category of students' beliefs connected to a deliberate activity, in this case, choosing a certain course. Students' relevance beliefs can be mediated by the mathematical content, but also by interactions with others. A different category of relevance beliefs is part of teachers' beliefs and pertains to a teacher's perception of the relevance of mathematics to their students.

In the Norwegian school system, students in upper secondary can choose among several mathematics courses with differing aims, scope and difficulty. Students make a selection while negotiating contradictions, such as those between the apparent irrelevance of school mathematics, and the image of mathematics that is drawn out in the media as a subject of paramount importance for the future economic development of society (Lange & Meaney, 2018; Valero, 2017). This duality puts the students who engage in the hardest mathematics in an interesting position: how do they reason about selecting and pursuing the most advanced mathematics course available to their age group? Once they are in this course, they encounter mathematical topics such as derivatives, integrals, and trigonometry. In the school system, they encounter little information on how these mathematical topics are useful out-of-school. The few situated tasks are quite inauthentic. Also, teachers of such courses, generally, have a background in university mathematics with little emphasis on the mathematics' use-value outside of the school context. Our research on students' relevance beliefs regarding school mathematics was operationalized by the research question 'what reasons do students provide for engaging in a challenging mathematics course?'

## Literature review

The discussion on the reasons for teaching mathematics has developed over the past two decades. According to Heymann (2003), mathematics is taught as preparation for later life, for promoting cultural competence, developing an understanding of the world, developing critical thinking, developing a willingness to assume responsibility, as practice in communication and cooperation, and to enhance student's self-esteem. Ernest (2005) provides a similar list, although he differentiates between reasons to teach practical versus advanced mathematics. In either case, it remains questionable whether students get to 'see' these reasons. Also, it has been argued that the above reasons remain at the pupil's level without considering the social role of school mathematics. For example, Pais (2013) suggests that school mathematics is important not only for its intrinsic purposes (use-value, aesthetics, etc.) but also because it has exchange value, for example as a testing and grading device that gives some students access to prestigious positions in society, and other students not. In the public discourse, school mathematics is typically associated with socio-economic development, in particular with the development of advanced technology (Lange & Meaney, 2018) and economic parameters on the individual and national level (Valero, 2017). In this cultural-political tug-of-war, it seems that school mathematics is struggling to communicate the use-value of mathematics.

A crucial challenge is the dialectics of two processes, the mathematization of knowledge and the demathematization of society (Jablonka & Gellert, 2007). The first has to do with mathematics being increasingly important in social, economic and political issues, for example in dealing with complex data through modelling and visualizations. This mathematization process is accompanied

by a demathematization process where mathematics is hidden and trivialized, for example when software encapsulates mathematical practices and datavisualizations can be generated in standardized formats by a few clicks.

Various teaching approaches to mediate relevance have been proposed. For example, in a study with engineering students, Hernandez-Martinez and Vos (2018) used tailored mathematical modelling activities and an invited talk by a professional to demonstrate how mathematics is used and valued amongst engineers. They found that several students experienced these activities as relevant to their future career, but some found the extra activities irrelevant, because their primary aim was to obtain a passing grade for the course.

### Theoretical background: Cultural-historical activity theory

To study relevance beliefs, we consider students as having different backgrounds (where they come from) and foregrounds (aspirations, opportunities). The term *foreground* was developed by Skovsmose (2005) as analytic construct for interpreting learning processes, and is framed within the students' current political, cultural and social context. Additionally, we wanted to capture students' engagement in activities (doing mathematical tasks), which take place within a community (a classroom, peers, etc.), in which there are norms and conventions (e.g. the answers must be correct), tools (incl. language and symbol systems). To engage into an activity, a person is driven by a motive. In order to capture how the student (subject) is connected to the community and the object (aim of the activity), we adopted cultural-historical activity theory (CHAT) (Engeström, 2015), in which an activity system is a basic unit of analysis, see Figure 1.

**Figure 1: Engeström's (2015) model for an activity system**

To analyse students' relevance beliefs, in particular their reasons for engaging with advanced mathematics, we assume that these can be affected by (1) the students' backgrounds (e.g. having a parent who uses mathematics in her workplace), (2) the environment in which the learning of mathematics takes place (the activity system of the classroom), and (3) the students' foreground (Skovsmose, 2005). This foreground can entail complex imagined activities, of which the student may not know much about; a student imagining herself as a future engineer may not know anything about the daily activities of an engineer, but nevertheless can aspire to become one. Thus, the activities envisioned in a student's foreground are not *realized activity systems* but *emergent activity systems*.

## Method

To find participants, we contacted a teacher from an urban public upper secondary school. The teacher and the school were well-known to the first author, as he had previously worked there. The teacher agreed and informed the students in his class about the project in advance. Thus, students had time to consider whether or not they wanted to participate. When the interviewer visited the class, eight students (3 f, 5 m) agreed to participate. The interviews were conducted three days later.

The students were in grade 12, which in Norway is the second year in upper secondary school, and the year before the final exams. All had chosen the most challenging mathematics course available, referred to as *R1*, the name used in the local context. The students were interviewed in pairs for mutual support and comfort. All student names were anonymized, and the pairs follow the alphabet: A(ndré) and B(jørn); C(hristian) and D(aniel) and so on. The student pairs were interviewed for approximately 20 minutes on their back- and foregrounds. The interviews were semi-structured (Wellington, 2015) and the interview guide followed Kvale and Brinkmann (2015).

All interviews were audio-taped, transcribed, and analyzed using Skovsmose's (2005) constructs of back- and foreground, and the CHAT frame by identifying activity systems, particularly communities and associated objects and whether the activity systems were emergent or not. The statements were then interpreted in terms of relevance beliefs based on categories from the literature (exchange-value, use-value) and themes emerging from the data (Wellington, 2015).

## Results

In the following, we present excerpts from the interviews. Due to space limitations, some answers very similar to others were left out. First, we asked the students why they chose the R1 course:

- |           |                                                                                                                                                                                                                                                                                                                                |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Bjørn:    | I like mathematics and get good grades.                                                                                                                                                                                                                                                                                        |
| Daniel:   | It's pressure from parents of course, and also some from my friends. Many of them are performing very well. I want to be on the same level, you know. Also, I suppose, career aspirations and further studies are... about having a relatively high-educated job which pays well... and is fun. I think that's very important. |
| Fredrik:  | The reason I chose R1, it is kind of a continuation. I always performed well in maths ... and it went well in grade 11, so R1 was the natural choice.                                                                                                                                                                          |
| Gjertrud: | I think math is fun. It's great fun when you get the same answer as the answer list. There aren't tons of pages about "it may be this", or "it may be that". It's great!                                                                                                                                                       |
| Hilde:    | Because I want to keep the possibilities open because I don't know what to do next.                                                                                                                                                                                                                                            |

We see that students reacted very differently to this question. Two students, Gjertrud and Bjørn, answered to have chosen R1 because they liked mathematics, whereby Gjertrud emphasizes the clarity, and Bjørn likes getting good grades. Their answers are within the activity system of the present classroom, unlike the other students, who mention their background (e.g. parents' pressure, having been good in maths in the past), or their foregrounds (e.g. keeping options open, getting a

well-paid job). The second question asked the students explicitly about wishes and ambitions for future studies and career (foregrounds). They answered as follows:

- André: Likely that it'll be something related to science or technology. Or I'd study sports!
- Bjørn: I'm very unsure about further education, but probably I will do some university studies, and that will most likely be within science or technology. But I don't know much more than that, really, I'm a little unsure. It could be sports but it could also be social anthropology or psychology, those are things that I'm also interested in.
- Christian: I always had a dream of going into ... engineering direction for example ... be a marine engineer. That's what I have always wanted. But ... I don't know yet. I like to draw things, be creative, look at buildings, how they are built. And boats, how they break waves, how they manage to stay on water, not go down, like that.
- Emilie: I don't know what I want to become, but I'm taking IB [International Baccalaureate, a prestigious examination program] next year and then perhaps NTNU [Norwegian University of Science and Technology].
- Fredrik: I just try to keep all the doors open.
- Gjertrud: I think it will be something within science, like biology. But I also want to study psychology, I think everything is very exciting and I can't decide!
- Hilde: Nothing (...) I don't know.

The question on students' foreground showed that all students mentioned a future, but the range and focus differed. With the exception of Christian who had a clear goal, all were insecure and wished to keep options open. Many of them indicated future studies, most of which were within science and technology, and no one mentioned economy or business administration. Above, we see only Christian and Emilie mentioning a future profession beyond their studies, although for Emilie it was vaguer than for Christian. Towards the end of the interview, we asked why they thought they had to learn mathematics:

- André: I think [maths] is mostly about ... just having the foundation for further study.
- Bjørn: I think maths is really only about testing understanding and testing how the mind can assemble patterns and stuff. (...) it's about exercising the mind, IQ-testing ...
- Christian: ... ehh I think especially the maths we are learning now, for example, we will need it in physics. It is ideal for the ... calculations there ... to figure things out there.
- Daniel: I think a lot of mathematics we're learning is a little redundant. Of course, I see that many topics can be useful. Like what we're learning about now with differentiation, I think finding rate of change everywhere, can be relevant. But there are also the unnecessary things. Logarithms are actually one of the things that I'm not so sure of whether it is useful or not.

Emilie: I can help my kids, my little brother [with homework].

Gjertrud: I really feel that what we're learning is, like, further, that we're learning something we can use for ... Just like when you learned the multiplication table. Why do we need to learn multiplication? Now I use it all the time.

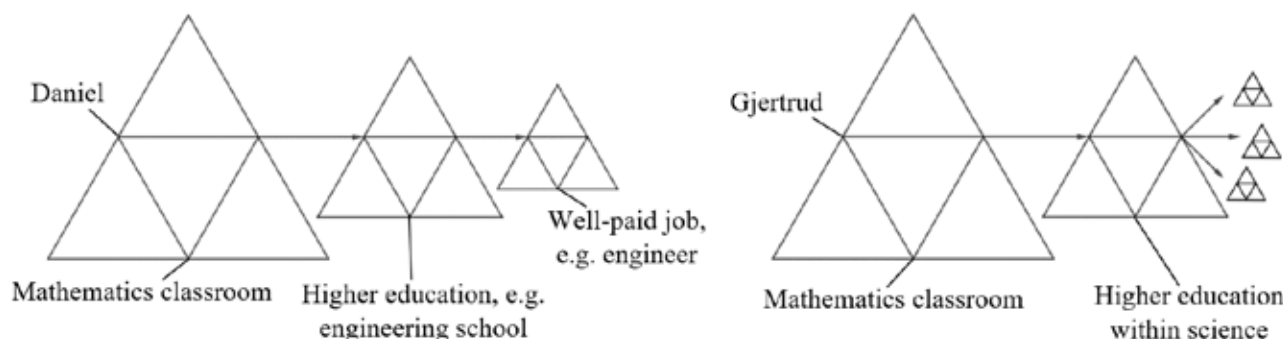

Most of the students considered their foreground. They mentioned that mathematics can be useful in future activities, for example in future studies. One student, Daniel, expressed concern that some mathematical topics may be useless. Only one student, Bjørn, considered the present activity system of the classroom when mentioning that the subject of mathematics has the purpose to train and test students' mental abilities. Emilie considered her present and emerging family activity system when she mentioned helping her kids and little brother. However, we must acknowledge that by first asking the students about their foregrounds, we primed the students to focus on their foregrounds thus biasing them towards focusing on the exchange value of mathematics.

## Conclusion, Discussion, Recommendations

The present study on relevance beliefs was guided by the research question: what reasons do students provide for engaging in a challenging mathematics course, R1?. The interviews revealed that for some students, their backgrounds (parents, earlier success) and their present achievement and enjoyment in mathematics play a role. However, most students mentioned the belief that the R1 course is relevant for their future. Here, we saw different patterns emerging. For example, Daniel ("I want a relatively high-educated job which pays well... and is fun") did not have a concrete plan for his future and strived to "keep his doors open", he aspired a high-status job, possibly within engineering. Similarly, Christian ("I always had a dream of going into engineering and be a marine engineer") looked beyond the course. The object of their engagement in the mathematics classroom had an exchange-value for getting into some form of higher education that led to a desired job. Their image of activities in higher education and workplaces were emerging activity systems, rather than realized activity systems. So, two subsequent emerging activity systems are in their foreground, see Figure 2 (left). For other students, such as Emilie ("I don't know what I want to become, but I'm taking IB and then perhaps NTNU") and Gjertrud ("It will be something within natural sciences, everything is exciting, I can't really decide"), the R1 course was relevant as having exchange-value to enter some form of higher education and keep options open. They looked at a nearer future in higher education without concrete ambitions regarding professions. Thus, their foreground was one or more emergent activity systems at early stages, see Figure 2 (right).

Two students believed mathematics to be useful, for other subjects (Christian mentions physics) or in an undefined use (Gjertrud: "we're learning something we can use"). Not one mentioned usefulness for their daily life, nor did they say anything about how mathematics can be useful, for example in modelling, data analysis or data visualization. Others believed that some mathematics could be useless (Daniel: "logarithms, I'm not sure of whether it is useful"). They also mentioned the mental strengthening function of mathematics (Bjørn: "exercising the mind"). The most frequently given reason for choosing the R1 course was that they believed it keeps their options open, apparently knowing the hurdle function of mathematics. This exchange-value of mathematics overshadowed its use-value, as already indicated by earlier research on Scandinavian secondary

students (Nosrati & Andrews, 2017; Pedersen, 2013). This suggests that a demathematization of school mathematics has happened, where the usefulness of mathematics has become obscured, and beliefs about other social functions of mathematics, for example its exchange-value, have taken over.

**Figure 2: Students realized activity systems in the mathematics classroom, with emergent activity systems as objects; the case of Daniel (left) and the case of Gjertrud (right)**

The networking of Engeström's (2015) and Skovsmose's (2005) theories proved fruitful in our analysis for connecting relevance beliefs to an activity (choosing a particular mathematics course). As a result of this, we found that for research on relevance beliefs regarding school mathematics, it is necessary to take into account students' (1) background, (2) current situation and (3) foreground.

Among the items on Heymann's (2003) list of reasons for teaching mathematics, the students on our study are clearly aware of its role in preparing for later life, although exclusively for further education and future workplace activities. The frequent reference to 'keeping all doors open' shows clearly that the students were aware of school mathematics' exchange value: a passing grade in this course is critical to many study programs that are otherwise not accessible. Furthermore, Daniel's assertion that the advanced mathematics course might lead to a "high-educated, well-paid and fun job" indicated an awareness of Pais' (2013) suggestion that school mathematics has a role in distributing prestigious positions in society. Based upon our research, we recommend, first, that beliefs may be divided into different categories, and 'relevance beliefs' regarding the usefulness of school mathematics is a separate category within students' belief system. Second, teachers, teacher educators and text book authors ought to create resources for students to inform them about the use-value of mathematics, not only within professions typically associated with mathematics (e.g. engineering and economy) but also its use-value in medical and social disciplines for purposes of modelling, analyzing, communicating and visualizing data. Clearly, many of the reasons for teaching mathematics mentioned in the literature have not reached the students.

*In pursuing the writing and presenting of ‘autonomous’ conference texts –i.e., conference texts functioning in terms of meaning making on their own–, all authors deal with issues of reduction, transformation and representation of the concepts and contexts of initiation and development of their research. In this introduction, we point to challenges tied to the writing and presenting of language-sensitive mathematics education research for communication in conference formats. We discuss some ideas for the improvement of current guidelines and standardised decisions relative to processes and texts produced within the CERME culture. Drawing on experiences provided through our roles as co-leaders of the ‘Mathematics and Language’ thematic working group (TWG09), along with the insights gained from the TWG09 set of papers and posters on the occasion of CERME11, each of us brings a focus to the discussion of challenges and changes that might be feasible and worthwhile.*

*Keywords: Research communication, conference formats, written and oral languages, language-sensitive mathematics education research, representational challenges.*

### Introduction

In conference papers, but also in journal articles, we often read sentences like “because of space restrictions, we do not show the totality of the interview transcript”, or “the lesson data transcribed has been translated into English”, “the lesson data translated into English have been transcribed”. It is also common to find written research without explanation of, or reference to, the original languages involved in data collection and/or the ways of addressing the transformation and reduction of data into certain written formats. These types of omissions and their implications at many levels deserve discussion in any domain of study. Such discussion is even more relevant in mathematics education research that is largely language-sensitive, regardless of the analytical traditions and theoretical standpoints taken. Indeed, throughout meetings of the ‘Mathematics and Language’ Thematic Working Group of ERME (TWG09), including the most recent meeting at CERME11 in Utrecht, many participants have expressed interest in challenging and improving some of the tacit typical practices when dealing with lesson and interview oral data in papers and posters.

In the following sections, we identify four major challenges around fostering a more language-responsive communication of research work, and propose specific changes and directions that could help in this respect. The two guiding questions that we pose to ourselves are as follows:

- What are some of the challenges of communicating language-sensitive mathematics education research in written and oral conference formats, particularly the CERME format?

- What changes in both the tacit positions of researchers and the written/oral products could improve the communication and understanding of the research reported?

Drawing on the experiences provided by our roles as co-leaders of TWG09, along with the insights gained from the TWG09 set of 28 papers and 2 posters on the occasion of CERME11, each of us brings a different focus to the discussion of challenges and changes that might be feasible and worthwhile. We hope that the sections below will give a sense of how research in the domain of mathematics education and language can inform important reflections for the whole field. Although there is increased understanding of the relevance of language in the various domains of mathematics education research, the point at which language issues are considered in written and oral conference formats is inconsistently reported and sometimes treated as a minor question. In our discussion below, each challenge is based on and arises in a number of papers and posters presented at CERME 11, however, each paper and each poster is only used once to illustrate the points being made.

### **The challenge of original language information**

The papers of Azrou, of Mizzi, of Prediger, Uribe and Kuzu, and of Salekhova and Tuktamishov are examples of work conducted in multilingual classroom settings addressing issues of mathematics education and language diversity. Mizzi provides two-column transcripts with the bilingual lesson data in the source languages, Maltese and English, in one column and the target English language in the other, hence doubling the length of the transcript in terms of space taken in the paper. When confronted with text formats of eight pages, doubling transcripts may require about two-thirds of the totality of the report for data presentation. In the papers of Azrou, of Prediger, Uribe and Kuzu, and of Salekhova and Tuktamishov, transcripts of the Arabic-French, Turkish-German and Tartan-Russian source versions of bilingual talk in the respective lessons are not shown, with all the written pieces of data translated into English, its alphabet and writing direction. Similarly, Ranges and Eikset refer to Norwegian students' home language, while presenting transcripts in English, and Rønning and Strømskag present data of conversations in a planning meeting with teachers of Norwegian schools in English. The use of Norwegian is limited to translating technical vocabulary and occasional incorrect terminology. In their presentations, some of these authors claimed practical reasons for the option chosen and particularly mentioned their willingness to share the original data with those participants who had further interest in their works.

Looking back at the whole set of papers and posters across ERME thematic working groups compiled in the CERME10 Proceedings (Dooley & Gueudet, 2017) and given the space restrictions, it is not surprising that the presence of original languages tends to be avoided with the resulting monolingual bias in the perception, representation and communication of the contexts of research. Any option in this respect is problematic. For those papers that incorporate information of original language with translated language text, accomplishment of space restrictions is not trivial. On the other hand, for all papers that have languages other than English in their contexts of research, translation between languages is not trivial either. At CERME11, in his paper, Sträßer refers to the many challenges of translating data and ideas from a source language to a target language (see also Geiger & Sträßer, 2015). Overall, we find several examples of papers dealing with the decision of how to communicate in English what is said in the source language. In Chesnais' paper, the discussion refers to French

grammatical features of the students' interactions, while the presentation of interaction transcripts and of their interpretation is done in English. This can also be found in Erath's paper, where the focus is on lexical and syntactical means produced in German but are presented and written in English. At the most recent meeting of TWG09, only the papers of Ingram and Andrews and of Postenilcu report work developed in a situation in which the source language of data is English exclusively.

Despite the difference of options being used, over these years the discussions in TWG09 clearly reveal that groups of authors, and in general all participants, consider data in the original languages as relevant evidence, not a technical distraction or tangential to the work we do. Reflections in this respect can be found in Planas, Chronaki, Rønning and Schütte (2015), Planas, Ingram, Rønning and Schütte (2017), Planas, Schütte and Morgan (2018), and Rønning and Planas (2013), among other CERME presentations and publications. The belief that untranslated source data is worthwhile, and that access to it is key, are strongly shared and rooted in our working group. We are very aware that untranslated source material retains a great deal of linguistic information that is of interest and can disappear in translation, with important implications for data analysis, interpretation and results. Importantly, the source languages provide vital information for gaining insight and understanding in multilingual contexts of mathematics education research, as well as for developing critical awareness of the monolingual emphasis under which most research products are shaped in our field.

Furthermore, the body of CERME Proceedings brings up paradoxical situations such as having a paper with the source data in French that is only read in its English translation by researchers who are French speakers or who are proficient in this source language and could therefore have a more comprehensive and direct understanding of the research reported in its original language. For each paper or poster, a number of researchers have the expertise and are able to review material in the original languages. With that in mind, CERME could possibly consider some changes oriented to facilitate access to the source languages without the necessity for a dramatic reduction of the space available for discussion in papers. In the age of technological developments and virtual environments, new arrangements could be made to include a multilingual site for registered access to repositories of source data matched with printable texts in the conference proceedings. Such arrangements would be similar to the practical experiences of what some journals do in the electronic version. This way, after consultation, authors could choose the option of linking their papers to the protected site containing information regarding the materials and texts that can be made available in the data's original languages. By using this option, authors could improve the communication of the research reported in the conference format.

### **The challenge of choosing what data is relevant for the paper**

The current practice of CERME papers is to offer authors who are transcribers the choice of two transcript styles. Either they may use Transcript or Numbered Transcript if the author needs to refer to specific lines in the text. However, the template does not number lines, it numbers turns. In language and interactional research within mathematics education, there is often a need to be more precise. For example, it is frequently interesting to consider interactions where two or more people are speaking at once, or when their turns overlap, particularly when considering classroom interactions where there are multiple speakers and the data is often messy, such as in the work by

Friesen, Schütte and Jung. Gestures, gazes and movements, such as pointing, that occur in social interaction are also often highly relevant to the analysis and these often occur concurrently with the spoken discourse. In these situations, line numbers rather than turn numbers are more appropriate, as well as the potential to use specifically designed transcription systems. Conforming to the transcription styles often results in a reduction of the data that members of TWG9 can present, and in some cases results in the loss of that data in the written presentation, as authors need to rely on their short presentation to share certain features of their data. More flexibility in the transcription formats is necessary if we are to offer closer representations of the language data that we are researching.

Greater flexibility in the transcription formats also implies some reference in the template for authors who choose to emphasize the multimodal nature of the data they work with, and who particularly do not produce verbal representations of gestures, body movements and uses of physical space and material objects, but opt for multimodal transcription systems. With the increasing use of video recording in our research field and the development of newer visual methods and analytical frameworks such as digital ethnography, the question of inserting photos and images in the transcript is very timely. Much of the research in TWG09 combines gestural, visual and verbal data, and hence goes beyond the purely verbal mode. This is the case of the papers by Fyhn and Hansen on how meaning of pattern changes depending upon the objects with which students are familiar and interact with, and by Götze on meaning-related language for understanding multiplication where the language is tightly associated with visual representations. The idea of communication ‘mode-switching’ (Sindoni, 2014), which relates to an important feature of multimodal data, is also present in the paper by Peters regarding learners’ reactions and responses to auditory material from radio podcasts.

Some theoretical traditions (e.g., conversation analysis, corpus linguistics) have a specific transcription system of annotation and coding associated with them where not only line numbers are required. There is a specific font and way of spacing transcripts to illustrate features such as pausing, overlapping speech and concurrent gestures (see the topic of transcription decisions and related representational differences and analytical implications in Ingram & Elliott, 2019). These systems often come with complex notation to indicate not only what was said, but also how it is said and this notation needs to be explained in the paper in order for the reader to make sense of the transcripts, which is another challenge to face in meeting the length requirements. Many of the papers in TWG09 are focusing on how students make sense of the mathematics they are engaging with, and this involves a combination of spoken interactions, written materials, and ways of interacting with objects. The current traditions around the written presentation of papers limit how this data can be shared as well as how much data can be shared. As suggested above, the repository of source data could enable the sharing of video or audio data that is often used during the presentations. This might also be a solution to the issue around the need to share transcription conventions, as well as offering an opportunity to share longer (multimodal) transcripts or additional transcripts for the interested reader.

## **The challenge of comprehensibility of theory development**

The last two challenges differ in nature to the previous ones since they focus on how to make theory and conceptual development more accessible to the readers and the audience. In the domain of mathematics and language, many researchers are guided by a qualitative-reconstructive methodology

and they use methods of qualitative social research in their inquiry design. The aim of many research endeavors is to reconstruct underlying structures and patterns of specialized verbal processes of negotiation through extensive analysis of data and the help of a comparative approach (“constant comparative method” in Strauss & Corbin, 1994, p. 273). Generally, research gaps can be identified and based on these gaps components of local theories or theories with limited scope but high comprehensibility are developed using the processes of conjecture and abduction (Peirce, 1991). In the conference proceedings and oral presentations of TWG09 –presumably similar to what happens in other working groups of CERME– only a small portion of the data can be communicated in form of a transcript. However, a transcript excerpt does not usually display, nor even illustrate with precision, the complex process of theory development. Rather, the process emerges across many structural comparisons within an analysis of constant selection of features, decontextualization to a certain degree, and theoretical abduction. In oral presentations and conference proceedings authors can usually only show the best possible visualization, explanation and synthesis of the developed theories, which are mostly striking examples from instances of data materials.

Some of the papers declare and address the challenge of presenting moving from concrete instances of data to theory development in the short space available. The papers by Sauerwein, by Keuch and Brandt, by Alfaro, by Bednorz, and by Umierski and Tiedemann all include some mention to the complexity of making theoretical development explicit and precise by means of the choice and use of selected empirical material. In some of these papers, the examples mirror the process of gradual theory development with local scope in a limited way and are not as comprehensible as originally intended or expected. The empirical material in the transcripts does not, and cannot, provide a sufficiently clear illustration of the theoretical argument. Cohors-Fresenborg and Mackay, Thurlings, Schüler-Meyer and Pepin, during the time for oral presentation of their respective posters, were reflective about the limits of communicating theory development and conceptual abstraction through the examination of examples. For understanding the concepts in the poster of Cohors-Fresenborg, for example, the relationship between what is observed in the lesson data and the scope of application of the concepts introduced by this author is very important.

For compatibility reasons with future research endeavors, especially from early career researchers, it would be preferable if publications and presentations could give a deeper insight into the cumulative process of theory development. Following the line of suggestions in the previous sections, this could also be made possible through a protected area, where researchers could provide further material for the working group. Thus, the gradual process of theory development for a certain period of time could be demonstrated and shared. This would include transcripts that are not yet published but were crucial for the forming of the developed theory components in the course of the constant comparative method. Additionally, there would be an opportunity to allow any author including early career researchers who have completed their PhD, to present their research process at the conference and give them the opportunity to publish a longer paper in the protected area. Anyone interested could hand in an 8-page paper, from which some could then be selected to be offered the opportunity to write a longer ‘master-paper’. All this would certainly contribute to the generation of more activity and transparency in theory building.

## The challenge of meeting informed audiences

The struggle of TWG09 participants to find new ways of expressing an updated understanding of what research on mathematics and language means today, and what the identity features of the domain are, frames the context for this last challenge. On the occasion of CERME11, due to the increase of the group size, a division of TWG09 into participants attending either Group 09A or Group 09B for all sessions was necessary. There were no ‘subtitles’ for the subgroups; rather, papers and posters were grouped into (usually) sets of threes by the TWG co-leaders, based on a perceived commonality among them. The organizational need for a practical division due to the number of participants, however, brought up a more profound conceptual discussion. Half of the papers had multilingual settings in common and hence, the recognition that a number of papers shared some multilingual specificity and fitted with each other was used in the final grouping. In the end, one language group consisted mostly of papers that considered language, interaction or mathematics within contexts that are (at least overtly) monolingual, as was the case for the paper of Theens (Swedish), and of Farrugia, which describes a context wherein English was used as *lingua franca*. In these studies, the languages of the speakers are (generally) not taken into account, unless the speakers themselves make it relevant. The second language group was then mostly constituted by papers wherein the presence of two or more languages in the mathematics classroom is a key element of the discussion, as were the papers of Schüler-Meyer, Prediger and Weinert (German-Turkish), of Ní Ríordáin and Flanagan (Irish-English), and of Chico (Catalan-Spanish).

While the arrangement appeared to make sense and to ‘work’, and participants’ collaboration ensured that things ran smoothly, during the last day it was suggested that multilingual specificity and interactional foci had been central to both Group 09A and Group 09B. In fact, throughout the working sessions the emergent discussion of the multilingual specificity in the papers presented in each subgroup became somehow problematic. The characteristic of ‘multilingual’ as being restricted to group languages was unintentionally suggested at some points in the discussions of the two subgroups and hence, the broader interpretation of switching between vocabularies, grammatical constructions, intonations, gestures, and so on was less attended to in one of the subgroups but considered in parallel to multilingualism in the other. For a long time, our group has discussed studies that focus on linguistic challenges faced by students that are not necessarily related to a diversity of ‘natural’ language systems but generally involve multilingualism in the form of (mode) switching between ways of communicating in mathematics lessons. In his paper at Utrecht, for example, Gíslason presented the linguistic and communication repertoires and challenges faced by students who are low attaining in mathematics. The determination of operational criteria for splitting TWG9 is not trivial at all and what is difficult indeed is to find labels of conceptual distinctiveness that do not diminish the opportunities for all participants to share their research with the interested audience.

In particular, the challenge of the group size with the subsequent splitting of TWG09 leads to the challenge of allocating the papers and posters for their presentation to the most appropriate audience. The conference format of short presentations does not allow much time for clarification of approaches and meanings that participants in the audience must then infer. What can be a rather comprehensible presentation for an audience, may not be equally comprehensible for an audience unfamiliar with specific theoretical stances and research emphases. With respect to this situation, it seems again

important to offer authors the possibility of uploading additional material of their work in a protected site so that other participants can more easily follow the ideas and reasoning both in advance and after the working sessions. It is important, for instance, to know what is involved in the use of common terms like ‘*linguaging*’ that may refer to very different stances and emphases (Shohamy, 2006). As can be attested by the variety of topics addressed by the papers and posters in TWG09, studying language in mathematics education may take many forms of *linguaging*, some of which involve different ‘*natural*’ languages or language systems, while some others are related to the alternation of discursive practices necessary for participation in mathematical activity. The papers by Fetzner and by Albano, Coppola and Ferrari show a kind of *linguaging* focused on written practices of argumentation, with shifts between ‘*natural*’, symbolic and pictorial languages within one language system (German/Italian). Other papers with multilingual lesson data show a kind of *linguaging* placed in the newer tradition of ‘*translinguaging*’ as the act of utilizing one’s full linguistic repertoire (García & Kleyn, 2016). Participants also need to know what is involved in the use of the term ‘*multilingual*’. TWG09 participants are aware that attempting to talk about group languages in the classroom context as separate (or separable) systems is artificial and hence, unhelpful for research purposes, but there may be substantially different ways of considering multilingual specificity in data. Of course, the use of group languages overlaps with the use of classroom- or subject-specific discursive practices, so that ‘*language in the mathematics classroom*’ is a complex area of study with a number of stances and emphases that cannot be introduced in short presentations.

We anticipate that the group size will require organizational measures in the near future. Due to the overlap between general language or discursive elements and the ‘*media of instruction*’ of the classroom, but also to questions regarding the precise meaning for contested terms in the domain, it would be important that the two subgroups find the time to have a joint session. There is a lot of commonality in the theoretical and methodological approaches that all members of the group draw upon or consider in their work, and thus identity distinctiveness should be addressed very cautiously. It will be an internal decision amongst TWG09 participants as to how to utilize the separate and joint sessions, in order to encourage fruitful and deeper discussion; however, it will be equally crucial that the CERME organization allows for the flexibility needed with regard to the organization of sessions as well as the provision of additional information and materials.

### **More challenges in what comes next**

The idea for this introduction paper began as a response to guiding questions posed to ourselves regarding challenges and revisable options of communicating language-sensitive mathematics education research in the written and oral CERME formats. Attention to these questions has been of help to uncover a number of theoretical and reflective issues behind the intricacies of improving the representation and sharing of our work within the CERME community. In our role of co-leaders we have done our best to become openly critical in bringing together some of the challenges that emerge when addressing the writing and presenting of language-sensitive mathematics education research for communication in conference formats. Despite the focus on, and discussion of, conference formats, we can also learn something important about the heterogeneous nature and theoretical complexity of the activity that goes in TWG09. Some of these many different challenges and approaches to mathematics education research on language will be investigated more closely in the diverse papers

and posters that constitute this chapter of the proceedings. Through these papers and posters, we will be able to find out what the authors themselves consider the challenges to be that make a strong case for their studies and professional development as researchers in the domain. The creative dialogue with all their points of view will enrich what we have written in more specific and unique ways.

# Taking advantage of the different types of mathematical languages to promote students' meaningful learning

Helen Alfaro Viquez

University of Tampere, Finland; helen.alfaroviquez@tuni.fi

*The low performance in mathematics of non-mathematics majors has forced higher education institutions to implement different measures to address the problem. Many of these measures have focused on curriculum modifications. This study presents a methodological way of approaching the problem, using written exercises, which combine symbolic, natural and pictorial languages to improve the mathematical learning of university students. These exercises promote the development of essential mathematical skills to achieve successful mathematical learning. In this paper, I describe one exercise and analyze the solutions of 28 students of Calculus 1 course, at the University of Costa Rica. The results suggest that the exercises allow exploring the benefits of different mathematical languages, so that the students can make connections between knowledge and theoretical concepts.*

**Keywords:** *Mathematical languages, university mathematics education, languaging exercises.*

## Introduction

During the last few years, improving the mathematics performance of university students has been an important issue. Special attention has been paid to students of non-mathematics majors in the transition process from school to university (Goodchild & Rønning, 2014), since the students' mathematical background is not strong enough when they enter university. They may reach the levels of reproduction of procedures, but without understanding the mathematical significance of the contents involved (Winsløw et al., 2018). Thus, the students do not have the level of mathematical reasoning, abstract thinking and rigor required at university (Gruenwald, Klymchuk, & Jovanoski, 2004). This situation is reflected in the alarming failure and dropout rates presented in the initial courses, from many students who have mathematics in their academic programs (Biza et al., 2016).

This gap in the mathematical knowledge of students has led universities to implement several measures to improve the problem. For instance, peer work, bridging courses, mathematical support centers, interactive lectures, videos, digital assessment, among others (Mustoe & Lawson, 2002). White-Fredette (2009) highlights that the actions taken for facing this situation should consider the instructional level. Similarly, Gruenwald et al. (2004) suggest that teachers should look for effective ways to help students to “understand the abstract concepts, master the formal language, follow rigorous reasoning, get a good feeling for the mathematical objects and acquire so-called mathematical maturity” (p. 12). In a nutshell, attention should be paid to the students' understanding of the mathematical concepts and the need to develop their mathematical thinking.

Considering this need, I present the written languaging exercises as a teaching resource to improve the understanding of mathematical concepts by students, using different languages. The exercises ask students to provide written explanations or justifications using symbols, drawings or their own words. In this way, they must organize their thoughts and review the reasoning that led to their solution, being aware of the knowledge and concepts used, and the connection between them. In Finland, the

linguaging exercises applied in university engineering mathematics (Joutsenlahti, Ali-Löytty, & Pohjolainen, 2016) and honor mathematics courses (Silius et al., 2011) have showed promising results. In this paper, I present the outcomes of applying linguaging exercises in a Calculus I course for non-mathematics majors in Costa Rica.

## **Theoretical background**

As literature indicates, it is necessary to promote conceptual understanding in students (Engelbrecht & Harding, 2015), teach them how to make connections between concepts (Nardi, 1996) and how to deal with the abstract nature of mathematical concepts and the complexity of mathematical thinking (Biza et al., 2016) required at the university level. Those actions may help students to experience a successful learning of mathematics and facilitate the process of transition from school to university. The mathematical proficiency theory offered by Kilpatrick, Swafford, and Findell (2001), proposes the development of key mathematical skills that help in this purpose. The theory suggests five main competences that are necessary to accomplish effective mathematics learning: conceptual understanding, procedural fluency, strategic competence, adaptive reasoning and productive disposition. These competences promote, among other, the ability to identify connections between concepts; to understand and provide justifications and reasons for procedures; to perform procedures flexibly, accurately and efficiently, knowing how, when and why to do it; to think logically, to represent, formulate and solve mathematical problems in different context; and to consider different strategies of solution. All the strands are therefore interwoven and should be practiced equivalently.

The mathematical proficiency competences can be developed by means of linguaging exercises, which are designed based on the linguaging theory. Linguaging is defined as the students' expression of their mathematical thinking using different languages (Joutsenlahti et al., 2016), including mathematical symbolic language (SL), natural language (NL) and pictorial language (PL). In this way, the linguaging written exercises combine models and tasks, which aim to promote different mathematics competencies. As well, the exercises use different languages to access the characteristics of the mathematical objects and students' mathematical thinking.

Languages play an important role in mathematics communication. Following the semiotic approach, it is a tool for representation, communication, thinking and constructing knowledge (Schleppegrell, 2010). Lemke (2003) argues that the integration and cross-referring of NL, SL and PL languages "form a single unified system for meaning-making" (p. 215) and is the combination of them that make possible the mathematical reasoning (Schleppegrell, 2010). In addition, research evidence that for students, the use of the three languages facilitates the understanding of concepts and mathematical exercises (e.g. Alfaro, 2018; Joutsenlahti et al., 2016). The use of different languages allows the exploration of more properties of a mathematical object than using only one (Dreher, Kuntze & Lerman, 2016), because each one shows specific features and connotations (O' Halloran, 2015).

The choice of written linguaging exercises is based on research which suggests that by writing, students have to organize their thoughts, review and clarify the mental processes they went through in the solution of a task (Morgan, 2002). Furthermore, they must try to express it in a clear and concrete way, so that readers can understand their mathematical thinking (Morgan, 2002). According to Kline and Ishii (2008), this process improves students' understanding.

## Context and method

Due to the high rates of failure of non-mathematics majors in Calculus 1 course in the University of Costa Rica, the School of Mathematics decided to introduce the pre-calculus course, in order to provide students with the necessary knowledge for studying mathematics at university level. However, the high failure rates simply transferred to this new course, and the problem remains unsolved. Therefore, in this study, I suggest a different way of approaching the problem, with a resource that can be introduced in classes for students to have meaningful learning, by analyzing their solution processes when they have to write or explain them.

These languaging exercises were applied to 28 voluntary participants of non-mathematics major taking Calculus 1 course at the University of Costa Rica. There were 17 languaging exercises (see Alfaro, 2018, for details) that were used in class or as homework during the study of the derivative. The exercises were designed combining different tasks, including: explain with your own words, complete missing steps, identify mistakes, argumentation of the solution, organizing solution steps, and follow given solutions; combined with the use of the three languages. The purpose of the exercises is to promote the different competences of the mathematical proficiency theory, especially procedural proficiency, conceptual understanding and adapting reasoning; and to allow students to experience the use of different languages to express their thoughts.

The aim of this paper is to answer the research question: how the students' understanding of the cases where the function is not derivable, can be evidenced by SL, NL and PL. For that purpose, I describe one exercise (number 3) which exemplifies the use of the three languages to make different representations of a mathematical knowledge. The intention is to provide evidence of the languaging exercises as an effective teaching resource for improving students understanding of mathematical concepts. For the analysis of students' solutions, I did a qualitative analysis based on the established knowledge of derivatives for the Calculus I course, studies about students' difficulties with derivatives (e.g., Asiala et al., 1997) and my teaching experience.

### Description of the exercise

Exercise three (Figure 1) consists of a table that presents three cases in which a function is not derivable. Each case is exemplified with one language: symbolic, natural or pictorial, and the students must complete the empty boxes with examples in the missing languages respectively, as shown in Figure 1. The use of the three languages allows students to explore different characteristics and properties of each case. Case I is described in NL with the phrase "At points where the curve presents peaks, since the lateral derivatives would be different." This statement has several characteristics. First, it does not refer to a particular function; therefore, students are not limited to the examples they can provide. In addition, it emphasizes the pictorial features by mentioning the graphical form (sharp points) of the function where the derivability requirement is violated. Finally, it refers to the theoretical aspect that fails (the lateral derivatives are different as shown in Figure 1).

For the case II, the example is given in SL, and refers to the situation in which the function has a vertical tangent line, at a point. This example refers to a specific function. However, the students must interpret from the symbolic expression what case it refers. It means that the student has to recall the definition of derivability to identify the characteristic that makes the function not derivable. Finally,

case III shows a graph of a function that presents a discontinuity in the point  $x_0$ . As in the previous case, the student must identify which case is presented in order to express it in NL.

The objective of the exercise is to observe if students understand the concepts and rules involved, in such a way that they can interpret them from any of the given representations and can express them in different ways.

What are the possible cases in which a function is not derivable?  
Give examples of each of them using the three types of language.

	Mathematical symbolic: numbers, symbols.	Natural Language: written words.	Pictorial Language: drawings, graphs, etc.
I		At points where the curve presents peaks, since the lateral derivatives would be different.	
II	$f(x) = \sqrt[3]{x}, \text{ in } x = 0$		
III			

Figure 1: Linguaging exercise #3

In the next section, I will present some excerpts of the students' solutions, as an evidence of the different uses of the languages they made, the different ways in which the students expressed the cases in their own words and some errors of interpretation and formality.

## Results and discussion

### Case I: Statement in natural language

For this case, students have to offer examples in symbolical and pictorial language. In the column of SL, they wrote diverse function samples such as absolute value and piecewise functions, with criteria of minor and greater complexity (Figure 2). As well, some included general expressions such as  $f'_-(c) \neq f'_+(c)$ , and calculated the values of the lateral derivatives.

<p>A) <math> x-2  = \begin{cases} x-2, &amp; x-2 \geq 0 \\ 2-x, &amp; x-2 &lt; 0 \end{cases}</math>  <math>c = x = 2</math></p>	<p>B) <math>f(x) = \begin{cases} \frac{1}{x} &amp; \text{si } x \leq -1 \\ x &amp; \text{si } -1 &lt; x \end{cases}</math>  <math>f'_-(-1) = \lim_{x \rightarrow -1^-} \frac{1}{x} = -1</math>  <math>f'_+(-1) = \lim_{x \rightarrow -1^+} x = -1</math></p>
-------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Figure 2: S9 and S15 examples in SL

In most cases, students ( $n=10$ ) did not make explicit in which point of the function the derivative does not exist, neither in the SL, nor in the PL. From this situation the questions of whether the students are aware of what is important in their example is the specific point where the derivative does not exist and what happens in it, can be raised. In the solutions in which it was possible to associate the example in SL with PL, one could verify if the student knew in what point the function described was not derivable by referencing the drawing. However, in the others, it was not clear. There were students' examples in which the function presented two cases where the derivative does not exist, and if they did not mark the point, one cannot know if they understood the case under discussion.

It is important to note that all the examples chosen by the students were correct and represented the given case, which means that they were able to interpret correctly the sentence in NL. In addition, by combining the SL and PL columns, it was possible to evaluate the students' abilities to graph functions correctly, pointing out asymptotes and points of intersection, as shown in Figure 3.

**Figure 3: Function with two cases of no derivability (S10)**

Finally, some errors of rigor can be observed when writing in SL, as in example B of Figure 2, where the student writes the limit without indicating the function involved.

### Case II: Example of the criteria of a function in SL

In this case, the most interesting results were presented in the NL column. In the PL column, most of the students drew the plot of the given function and a few drew the tangent line. The results in NL, however, show that the students were not sure about how to explain this case. Among the expressions, there were students ( $n=11$ ) who could not even identify what was happening, arguing that the function was indefinite at that point, was discontinuous, had vertical asymptote or was constant. Nevertheless, there were cases ( $n=8$ ) in which the students seemed unable to express their ideas in a mathematically correct way. Examples as such are when referring to a vertical line as the function: “where the function is a vertical line” or when associating the derivative with the line instead of the slope: “where the derivative is vertical.”

Within the phrases they used to explain the phenomenon in case two, we can identify different connections between concepts that students used to justify their claims. Some made references to the calculation of the limit of the derivative at that point and others properly to the relationship between the derivative and the slope. Examples can be found in Table 1. Although in these sentences one can identify some conceptual errors, such as the idea of a “vertical function”, they show that the students had an idea of what was happening in the given case.

---

*When the tangent of the point is vertical, as in this case, it is considered that the function is not derivable at that point. (S3)*

*In the points where there are vertical lines, because this has no slope and therefore has no derivative. (S15)*

*In the points where the derivative tends to  $+\infty$ , since this would mean a perpendicular tangent line, which does not exist. (S10)*

*When solving the limit results in  $\frac{x}{0}$ , then it is a vertical function. (S5)*

---

**Table 1: Students' answers in NL**

### Case III: The graphic of a discontinuous function

The task of the students in this case was to complete the SL and NL columns. In the SL column, responses with different characteristics were presented. Some students wrote piecewise functions in

which, as in case one, they forgot to point out the point of discontinuity. However, in other cases, the students, in addition to the criterion of the function and the point where the function was not derivable, also added the calculations of the conditions of continuity: lateral limits and the value of image in the point (Figure 4A). This was also evidenced in answers as in figure 4B. Nevertheless, in this case they used a more general form.

<p>A)</p> $f(x) = \begin{cases} 2x-1 & x \geq 3 \\ x^2-2x-2 & x < 3 \end{cases}$ <p>1) <math>f(3) = 5</math></p> <p>2) <math>\lim_{x \rightarrow 3^-} f(x) = 1</math>   <math>\lim_{x \rightarrow 3^+} f(x) = 2</math>  <math>\lim_{x \rightarrow 3} f(x) = \text{no existe}</math></p> <p>3) <math>f(3) \neq \lim_{x \rightarrow 3} f(x)</math></p>	<p>B)</p> $f(a) \neq \lim_{x \rightarrow a} f(x)$ $\nexists \lim_{x \rightarrow a} f(x)$
----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------	------------------------------------------------------------------------------------------

Figure 4: S12 and S4 examples in SL

Regarding the answers in NL, students were able to express the case of discontinuity recurring to the graphical feature of the “jump” or “breaks” ( $n=2$ ) and others mentioned conceptual aspects as the fact that the lateral limits were different or the that limit does not exist at the point ( $n=9$ ), the discontinuity of the function ( $n=15$ ) and the fact that if a function is not continuous in  $x = a$ , then it is not derivable in  $x = a$  ( $n=6$ ). Considering the different answers, it is possible to observe that students were able to recall different knowledge about continuity and the conditions of derivability to correctly explain what happened in the point.

## Final considerations

As stated at the beginning, when students begin their university studies, they lack mathematical skills and knowledge required for university level. I suggest languaging exercises as a methodological tool to address those issues and promote students’ meaningful learning. The written languaging exercises offer an option for boosting students’ understanding of mathematical concepts and noticing the connections between concepts, the rules and properties that justify the procedures and the different representations. The use of the three languages reinforces different strands of mathematical proficiency, such as conceptual understanding, adaptive reasoning and strategic competence. For example, from the results it is possible to conclude that for solving the exercise students must understand, identify and verbalize the connections between concepts, as well as represent mathematical situations in different situations. These actions are associated with conceptual understanding. It is important to highlight that in each case, in order to complete the empty boxes, the students had to interpret the given example, and from that point they were already connecting between representations. The adaptive reasoning is evidenced in the justifications and explanations that the students provide in natural language, and the strategic competence is present since the task presented to the students is not common for them, so they must show a flexible approach to solve this novel situation. All these actions helped them to experience meaningful learning and think about the concepts involved in the exercises instead of solving them mechanically.

The different languages allow studying different characteristics of the mathematical concepts involved. NL evidenced the theoretical knowledge involved and, how the connections between the ideas were made. SL showed aspects related to the correct use of the symbols and specificities in relation to the examples, as in the mention of the point where the derivability was violated. In PL, all

the features were combined and represented. In addition, the use of different languages makes it possible to observe the gaps in knowledge, misconceptions or difficulties the students have. As evidenced in case 2, where most of the students could make the graph from the interpretation of the symbolic expression, but they faced problems when trying to explain the situation in NL, for which deeper knowledge of the subject was required.

This experience shows the potential of the use of different languages to improve the mathematical learning of the non-mathematics major students and to promote their competences to become mathematically proficient. However, more studies are required to explore various ways to integrate different languages in mathematics learning at the university level.

# Learning mathematics in French at the undergraduate level in Algeria

Nadia Azrou

University of Yahia Fares, Faculty of Sciences, Medea, Algeria; [nadiazrou@gmail.com](mailto:nadiazrou@gmail.com)

*In this paper, some students' difficulties, related to learning mathematics in a second language (French) when entering university, in Algeria, are examined. I present these difficulties as part of other difficulties caused by the transition from high school to university. The analysis of students' interviews, using Cummins' theoretical framework, revealed that low mastery of French as natural language and low mastery of Arabic as academic language impeded several students from performing well in mathematics and expressing them in French academic language.*

*Keywords: French as second language, learning mathematics, students' difficulties.*

## Introduction

While mathematics is often seen as language free, in many ways learning mathematics fundamentally depends on language (Barwell, 2008; Planas, 2014). The relationship between language and mathematics has been considered within a range of perspectives: political perspective, social and cultural perspectives, epistemological perspective and cognitive perspective. Learning mathematics in a second language at different school levels has also been a subject of many investigations.

On the other hand, Ní Ríordáin and O'Donoghue (2007) expose two opposite positions about learning mathematics in a second language with many references; studies which argue about positive aspects and satisfying achievement (immersion programs) and studies which argue about the underachievement of pupils (submersion programs). Research about teaching and learning mathematics in a second or a third language is very popular at many school levels, but little research has investigated this issue at the undergraduate level so far.

The present study has been motivated by a PhD research about undergraduates' difficulties with proof and proving in Algerian universities. The findings indicated that the weak mastery of French as a second language for learning mathematics was one of the reasons for third year university student' difficulties with writing a proof text. Even though I acknowledge that low students' proficiency in languages is associated with underachievement in mathematics (Cummins, 2000), I tried to understand better how this really works. In this paper, I studied this relationship particularly with students at the beginning of the university, where they learn mathematics completely in French for the first time. I focused on the mathematical difficulties that are originated in the relationships between French language, dialect and Arabic considered as tools to approach, develop and report mathematical thinking; I also investigated students' behaviours when they make mathematics in French and their related opinions.

## Linguistic overview of Algeria

Algerian population communicate in different languages, according to different regions, ethnic groups, institutions and circumstances. The most spread languages are Classical Arabic, Dialect, Berber language and French (first foreign language). Classical Arabic is shared by Arabic countries. The Dialect is the common language; it is the most used spoken language in daily life in Algeria; it's

a mixture of classical Arabic, French and other languages (Spanish, Turkish, Italian...). In Algeria, people speak in their families either Berber language (indigenous language) or dialect, which is the same in all the country with slight differences in some words and accents. The language of instruction in schools is classical Arabic, so children learn from primary school on in a different language. Only Arabic language is used for writing, but for the oral, the situation has declined; around thirty years ago, Arabic language was used also for the oral, but dialect has been used more and more. Actually, it's rare for teachers and students to speak only Arabic in the school. French is the first foreign language in Algeria, it is taught from grade 3 to grade 12. With the exception of French language, all courses in all school levels are taught in classical Arabic. Teaching French has been affected during the dark decade of the civil war (1990-2000) by the lack of teachers in many regions; consequently, many students have not had French courses for many years. On the other hand, the technological development and the increasing use of English for computers, cell phones and social media have pushed students to be distant from French. At the end of high school level it is quite rare to find students who master correctly the speaking and the writing of this language, in spite of ten years of learning French.

### Languages of teaching mathematics in Algeria

The teaching of mathematics in Algeria has shifted from French to classical Arabic (oral, writing and mathematical symbols) for the three school levels (primary, middle and secondary school) since the 70's. Teaching mathematics in classical Arabic (including Arabic symbolism) has lasted more than thirty years, till the beginning of the 21<sup>st</sup> century, when it shifted again. In 2005, there was a big change in teaching mathematics: in school formulas and symbols are written from left to right with Latin alphabet (that stands for French), while comments, terminology and verbal expressions are maintained in classical Arabic (from right to left). This is an example to see how to read and write in both senses: the area of the square ABCD is equal to 20 m<sup>2</sup> (arrows show the direction to read).

$$\text{مساحة المربع ABCD تساوي } 20 \text{ m}^2$$

This reform has been undertaken to make the transition to university mathematics (taught in French) less difficult. However, this situation has resulted in a mess and caused some difficulties for students at different school levels. The language of higher education, in Algeria, has always been French for scientific and technical disciplines (medicine, mathematics, architecture, computer science, engineering sciences, etc.) with French textbooks; while the other disciplines (history, Arabic literature, humanities, psychology, etc.) are taught in Arabic.

### Literature review

The interest is in investigating undergraduates' difficulties when they learn mathematics in a second language. Durand-Guerrier et al. (2016) pointed out delicate points related to language, which might present difficulties for students. In particular, same words in two languages have different mathematical meanings when we translate from a language to another (decimal in English and decimal in French); and even mathematical notations that "contain a lot of information, so that being able to decode or unpack such information is an important part of mathematical proficiency" (Durand-

Guerrier et al., 2016, p. 87), like gcd (greater common divisor). The difficulty of interpreting formal statements in their native language that undergraduate face might be worsened when learning in a second language. Students might have problems when they learn new mathematical words they already know in the natural language (like group or distance) “learning the new vocabulary that is centrally mathematical may be easier than learning the technical meanings for words that students already know in other contexts” (Schleppegrell, 2007, p. 142). Students should be encouraged to express mathematics using a language, otherwise, their learning would be sterile, “at college level, there are few opportunities to put into practice long term activities aimed at improving linguistic skills. Requiring high degrees of correctness to students with a poor linguistic background just means inducing them to learn by heart or to use stereotyped expressions with no understanding” (Ferrari, 2004, p. 389). When students do not master the second language they fail to understand their teachers communication (spoken and written), mostly the part that is expressed in a highly academic language; “the language of textbooks and instruction frequently calls for a high degree of familiarity with words, grammatical patterns, and styles of presentation and arguments that are wholly alien to ordinary informal talk (Fillmore, 1982, p. 6)” (Cuevas, 1984, p. 135); what Cummins (1980, p. 43) has identified as the difference between basic interpersonal communicative skills (BICS) and cognitive academic language proficiency (CALP) as “the manipulation of language related to literacy skills in academic situations” Another major issue is the assessment of mathematics achievement of students when made in the second language, many researchers argue that one principal reason for inappropriateness of tests is the use of language that students do not understand (Cuevas, 1984).

## Method

### Theoretical framework

Given that this research concerns difficulties of undergraduates when learning in a second language, it is important to examine how do students shift from Arabic to French and how do they behave with their teachers talking, and with their written courses. I will use, for the analysis, Cummins’ theory. Cummins distinguishes between conversational and academic languages, as being respectively basic interpersonal communicative skills (BICS) and cognitive academic language proficiency (CALP). The latter is defined as “the extent to which an individual has access to and command of the oral and written academic registers of schooling” (Cummins, 2000, p. 67), in other words, it is the ability to think in and use a language as a tool for learning, by using abstractions in a sophisticated manner. What is important to note here is that, while second language learners may pick up oral proficiency (BICS) in their new language in as little as two years, it may take up to seven years to acquire the decontextualized language skills (CALP) necessary to function successfully in a second language classroom (Cummins, 1979). Later, Cummins expanded these concepts to include two different types of communication, depending on the context in which it is involved: context-embedded communication and context reduced communication; both concern conversational fluency and academic language proficiency. Context-embedded communication provides supports to the listener or the reader (as gestures, images or basic math computations) in order to make the information comprehensible. Context-reduced communication provides less support to understanding (as a phone conversation or lecture with few illustrations). Moreover, Cummins makes the difference between cognitively demanding and cognitively undemanding communications. And considers that BICS (in

both contexts) are cognitively undemanding, while both contexts of CALP are cognitively demanding, as shown in his model, illustrated in Figure 1.

**Figure 1: BICS and CALP (Cummins, 2000)**

This theory is furthered by his Interdependence Hypothesis, which proposes that the greater the level of academic language proficiency developed in the first language, the stronger the transfer of skills across to the second language (Cummins, 2000). I suppose that, for many students, BICS in French language are poor, which would effect the development of their CALP, and the few students who could have developed BICS in French, need much more time to develop their CALP. Moreover, I hypothesize that students did not develop university mathematics in an academic Arabic language in high school because school mathematics are reduced to algorithms and management of formulas that do not require such a level of academic language proficiency. Consequently, students are faced with the difficulty of going from context-embedded tasks (B quadrant, Figure 1) to context-reduced tasks (D quadrant), which is the most difficult for students.

### Formulation of research questions

I would like to answer the principal research question: How undergraduates' difficulties with mathematics are related to learning in French as a second language?

According to literature and my PhD work, I made two research sub-questions, each question related to specific difficulties, about how students deal with the teaching and learning of mathematics in French during the first university year, taking into consideration Cummins' theory. Being inspired by the research cited before and observing students and interacting with them as a teacher made us aware of some facts that stand for first hypotheses.

1. Students confuse some French words as they have close pronunciation in French, for example: 'ou', 'où' and 'd'où' (same pronunciation) which are 'or', 'where' and 'hence or thus'. Example:  $x=1$  ou  $x=0$ , où  $x \neq 0$ , d'où  $x=1$ , this might mean ' $x=0$ ' for a student who considers all of them as the same as 'ou (or)', (because 'P or Q' is true if either P or Q is true). Students miss the meaning of the uniqueness when we use 'le' or 'la' (as 'the') with the use of 'un' or 'une' (the article 'a') – a difficulty which might not depend on mastery of French only. When we talk about bases in vector spaces, we

say B is ‘une’ base and ‘la’ dimension because we can have more than one base for a vector space but only one dimension. This meaning packed in these articles is not clear for students.

RQ1. Why do students not perform well in French as an academic language? Is it only about second-language performance?

H1. I suppose that their weak BICS is a major reason for their problems in CALP. But also their CALP in Arabic has not been developed, which prevents them to make the transfer to French CALP.

2. Most of the time, students are not able to read parts of their course notes, written by them, because they might not know what is the meaning of what they wrote or even to spell exactly what they wrote (written sometimes wrong). In general, I perceive students’ big difficulties when I observe their behaviours when dealing with CALP with context reduced tasks (and communication). Taking into consideration that teachers write in French, explain in French and in Arabic (both classical and dialect), while students write in French – but several of French words are unknown to them.

RQ2. Why do students meet difficulties in managing their mathematics activities (reading, memorizing and revising their notes from lectures and exercises’ sessions)?

H2. I suppose that even if teachers would simplify their explanation in Arabic (or dialect), students face the difficulty of shifting between three languages when copying, revising the courses and writing their own responses in French.

### **Interviews and students’ responses**

In order to confirm my hypotheses and find out more about the difficulties of students when they learn mathematics in a second language, I designed semi-structured interviews for first university year (18-19 year old) students in the University of Medea (Algeria). The statistics show that more than half of the students (first year) fail, but only one third repeat the year. Eighteen students were chosen (half of them are male) within the discipline of mathematics and computer science. This discipline has two main courses, at the first year, algebra and analysis, where students manifest many difficulties. I included two students with very few difficulties and good marks, ten students with some difficulties and average marks, and six students who are remaking the first year (had many difficulties and low marks last year: RPT student). Interviews have been audio-recorded in May 2018. I have categorized the questions according to the two stated hypotheses as follows:

Q1. If teachers write and speak only in French, would it be better? H1.

R1. 18 students said ‘no’. *In the first year, some student are bad in French language, that’s why they give up when teachers speak and write only in French*; ‘no, it depends on the level of students in French language but for me, this method did not help me’ (4 RPT students).

Q2. If teachers translate orally into Arabic (classical and dialect), would it be better? H1

R2. 18 students said, yes. *We could at least follow what teachers is dealing with, otherwise, we are lost*; ‘if the teacher explains in Arabic, yes it would help us, because we memorize the words better’ (a RPT student).

Q3. When you make mathematics in French, do you translate to Arabic or do you try to understand in French language? H2

R3. 17 students said they always translate in Arabic then try to understand. *'I always translate to be able to understand in Arabic language'* (a RPT student).

Q4. How do students copy their courses in French? What if some words are not clear? H2

R4. 14 students said, they write everything even if they do not understand. *'we should copy, in case a word is not clear we copy it as it is'*. Students say they should copy any unclear words because they are part of the course: *'If the teacher wrote them, they are part of the course and must be important, so we copy them as they are, even if we have to draw them'*. *'Students do not ask questions about the unclear words, because they do not understand them and because they cannot speak French very well.'* One student said that he writes just what he needs (a good student), two students said, they write and try to understand, one student said *'when I write I try to understand what I am writing, and if I can't understand I ask the teacher to help, because if I try to translate maybe it's not the same meaning as the teacher's'* (a good student).

Q5. What happens when a student writes the solution, in French, on the exam-sheet? H1, H2

R5. All the 18 students declared to have difficulties with the use of words when they write their solution on the exam paper. Four students said, they wrote in classical Arabic if they could not write in French language. *'I am not good at French language so, if I can't write a solution in French I write in classical Arabic'* (a good student); *'Naturally, I translate the question in Arabic in order to get the solution but often when I try to shift into French language it is difficult'* (a RPT student); *'If I write something wrong the teacher would not understand it'*; *'I had always difficulties in writing the solution, this is why I'm always scared'* (a RPT student).

Q6. In which language do you think when you solve an exercise? H1, H2

R6. All students said, they think in Arabic language first, then they write their solution in French language. *'I think in Arabic to understand the question then I write in French language'* (a RPT student).

Q7. There is almost no student speaking good French and understanding perfectly French, but how did students who succeeded do, according to you? H1

R7. 10 students responded that students, who cannot speak French and succeeded, rely on memorization (3 RPT students). Among the responses *'I think those students learn with memorizing'*. 8 students said that students rely on mathematics formulas without using words, *'maybe they are good in mathematics and so they don't need language, they would use only symbols'*.

## Results of the analysis of the interviews

All students do not accept that teachers speak only in French, they need teachers speaking in Arabic to better understanding, according to responses to Q1 and Q2. Students who failed last year declared that they are lost if they hear explanations only in French; according to them, Arabic would help them also to memorize the words they need often in mathematics (as mathematical terms or as verbs and

words that are used regularly). Responses to Q3 and Q5 show that almost all students translate into Arabic language to understand mathematics (the exception was for one good student). In lack of developed CALP in Arabic language, translating in Arabic is not of much help too. In fact many confusions, and misunderstandings can occur. This validates H1 about weak mastery of natural language that affects logical aspects of mathematics.

Answers to questions Q4, Q5, and Q6 show that students have difficulties with the writing, most of them copy down what teachers wrote on the blackboard as it is, even without deciphering the letters. Because students believe that it is their job and cannot ask questions about unclear words (literally or semantically) as their understanding is very limited and also, because of their weak mastery of French language (to make a clear question). This impedes them to revise their course notes at home. The difficulty of writing is showed more during the exams, when students have to translate from Arabic (used to think), to French (used to write). Most students have doubts about their written texts to be not understood by the teacher when correcting them; consequently, they feel powerless and unconfident. These responses show the big difficulty when they deal with tasks involving context-reduced communication with a high cognitive level, as expected in H2. Responses to Q7 reveal two criteria that were mentioned by students: memorization and focusing on symbols and formulas. Students' conception of mathematics from their long school experience dictates them the fact that language is not so important. They believe that formulas or symbolic expressions are more important and so, language has a secondary role. In doing so, their BICS do not improve and so will be their CALP. This sustains H2.

## Conclusion

Students depend completely on translation, they expect teachers to talk in Arabic, explain in Arabic and translate all the words given in French. They also think in Arabic, translate in Arabic and then try to translate again to French for the writing. This fact shows that students' BICS in French is weak and will persist to be so. This fact persists longer as sustained by students' beliefs about language as being not so important in learning mathematics that are reduced to formulas and calculations. I also think that this belief is strengthened by the way they learnt mathematics before (formulas in French and verbal expressions in Arabic). They repeat the same experience: as mathematics in high school focus mainly on calculation, the role of Arabic language is minimal, consequently, students behave similarly with university mathematics whose formulas are clear for them (as they are written as before), and verbal language (in French) might not be important, as before. Thus, students would ignore verbal expressions and focus only on mathematical formulas; consequently, they might memorize a chain of formulas as a procedure for solving some exercises as they are used to do in high school. This is caused, according to me, by two important factors; the first one is due to their mathematical conception from school; that presents to students mostly exercises that are solved by a chain of formulas based on calculation rules. The second factor is the loss of the logical structure in mathematical statements and the lack of knowledge about the process of solving problems. This suggests the validity of H1. If students manage what teachers say orally in Arabic, when it comes to writing, students are in front of a difficult process. When they copy down from the board, they might lose the ideas they got before (in the listening process) because the words (in French) are meaningless for them, that is why they copy them incorrectly or just transcript them as they are presented. Under

the didactic contract, students think that they have to copy down what teachers write in the boards, even if it means nothing for them. Moreover, they hesitate and do not ask questions because their French is so weak. The problem of writing rises again, when students have to write by their own, the solution of the tasks of the exams. Students face serious difficulties with CALP with reduced context tasks. This validates H2.

# Textual configurations as an approach to evaluate textual difficulties of mathematical tasks

David Bednorz and Michael Kleine

Bielefeld University, Germany; [david.bednorz@uni-bielefeld.de](mailto:david.bednorz@uni-bielefeld.de)

*Language is a major factor in learning mathematics. Language learners or those with a low socioeconomic status have special difficulty solving mathematical tasks with high language demands. The project evaluates linguistic task difficulties in mathematics. This paper discusses the first step of the project: empirical evaluation of textual configurations and analysis of the lexical and grammatical structures of a corpus of 348 tasks. An explorative factor analysis is used to analyze the configuration of 17 linguistic variables. The analysis revealed a reduction of the variables to five factors, which are interpreted as different textual configurations of mathematical tasks based on their obligatory allocation of typical situational use. The structure offers potential for an empirical model to evaluate the difficulties.*

*Keywords: Language, language variation, mathematics education.*

## Introduction

Language is omnipresent in human life; it helps us to create a cultural base for human interaction. Language enables a direct interaction to make meaning between people. To define what language is and what potential relevance language has to learn math, this paper introduces the systemic functional linguistic (SFL) theory. The important theoretical terms to describe language for the analysis are the instantiation and realization of language. Furthermore, the notions of register and the contextual configuration are presented in the theoretical part of this paper. Registers and contextual configurations are only considered in terms of the objectives of the empirical results in this paper. Afterwards, the research questions of the project “Language Difficulties in Mathematical Tasks” (LIMiT) are presented, followed by the empirical method and the results of the factor analysis. Finally, a prospectus is made of the next goals of the project LIMiT.

## Theoretical framework

The framework conditions for successful pedagogical processes are constantly changing, and the importance of language is becoming more relevant for mathematics classrooms. In addition to the content specific requirements of mathematical tasks, language requirements are a factor that determines the complexity of mathematical tasks (Abedi & Lord, 2001). To solve tasks with content related subject, on the one hand students need to have contextual knowledge, which are essential to solve the problem which are presented in the tasks. On the other hand, the grammatical and lexical textual basis of mathematical tasks are important factors of difficulties for understanding (Abedi & Lord, 2001). In particular, language learners and learners with a low socioeconomic status show special difficulty in mastering mathematical tasks (Abedi, Hofstetter, & Baker, 2001; Haag & Heppt, 2015; Martiniello, 2008). The academic language and mathematical language are theoretical constructs to explain the language requirements in mathematics tasks (Maier & Schweiger, 1999; Morek & Heller, 2012; Prediger, Wilhelm, Büchter, Gürsoy, & Benholz, 2015). On the perspective of academic and

mathematical language as register, the difficulties can be explained by the variation of language. Register tend to vary, especially in lexical and grammatical features (Morek & Heller, 2012).

### **Language in mathematics classrooms**

With the focus on language variation, a possible theoretical approach to explain the relevance of language in mathematics classrooms is the SFL theory (Halliday, 2014; Halliday & Hasan, 1989). The SFL theory describes, theorizes and analyzes language through the meaning of the environment (Halliday, 2014). Language is considered in a systemic functional approach as a resource for making meaning. To develop meaning, humans use different kinds of semiotic systems which are useful or functional in a specific context (Eggins, 2004).

### **Instantiation of language**

According to Halliday (2014, p. 28) language is described through a “cline of instantiation”, with two different poles, one potential pole and one instance pole. On the instance pole, a specific textual instance is embedded in the context of a situation. The context of a situation is characterized after Halliday (2014) with three variables called field, mode and tenor. According to Eggins (2004, p. 90), field refers “what the language is being used to talk about”, mode describes the way language functions in interaction and tenor focuses on the relationship of interactants involved in the discourse which are a short description of the three variables. The potential of a particular language is described by the contextual conditions within a culture (Halliday, 2014). Halliday (2014, p. 33) defines this contextual potential of a community as the “context of culture”. The context of culture describes what members of a community may mean by cultural terms. Culture is described as a system of higher importance, as an environment of meanings in which different semiotic systems function. This describes a “multi-dimensional semiotic space” (Halliday, 2014, p. 34) that we also find in mathematics classrooms. The perspective for exploring culture is the reduction to specific cultural domains, such as analyzing different contexts of situations within an institution. The isolation of culture relative to the institution allows the linguistic analysis of language used within the institution.

### **The concept of register**

It is clear that situations vary depending on the location, time and participants. It is not quite so clear that at the same time, language varies corresponding to various situations. The notion of a register describes the variation in language in relation to the context of situation (Eggins, 2004). One viewpoint to define registers, especially for a quantitative purpose is that registers are systemic probabilities of the use of language in specific situations or a set of possibilities for the entry in a situation (Halliday, 2014; Halliday & Hasan, 1989). For example, symbolic notation will occur more frequently in mathematical texts than in stories, and the graphic proof of the Pythagorean theorem will occur more frequently or even exclusively in mathematical texts compared to geography textbooks. According to Morek and Heller (2012) as mentioned above, registers vary according to usage and tend to vary within semantics, especially in grammar and vocabulary. This leads us to Table 1, which shows a possible categorization for the variation of language in typical situations (Eggins, 2004). Furthermore, the three variables field, tenor and mode constitute the language used in a situation. Because of the changing situation, these three variables are also called register variables (Eggins, 2004). The value of

each register variable defines the language used in a text. Eggins (2004) combined the three variables with typical situations of use which enables a lexical and grammatical fixation of the systemic probability of specific lexical features.

Register variables	Field		Mode		Tenor	
Typical situations of language use	Everyday situation	Technical situation	Spoken language	Written language	Informal	Formal
Selection of characteristic features	everyday terms (words we all understand), standard syntax	technical terms (words only 'insiders' understand), acronyms, abbreviated syntax	everyday lexis, content-dependent, low lexical density, open-ended, non-standard grammar	prestige lexis, context independent, high lexical density, closed, standard grammar	attitudinal lexis, colloquial lexis, typical mood choices	neutral lexis, formal lexis, incongruent mood choices

**Table 1: Summary of register variables and characteristic features (Eggins, 2004)**

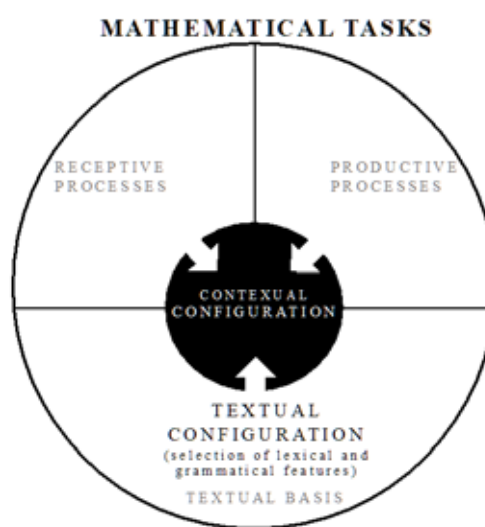

### Contextual configuration

Within cultural practice, similar linguistic structures or obligatory linguistic features are used among other things for pragmatic reasons. Halliday and Hasan (1989) describes these structures as contextual configurations which are recurring in similar situations. Similar situations, framed by a context of culture or an institutional basis, lead to the realization of specific values for field, tenor and mode, which can be described as a contextual configuration. The contextual configurations do not imply a concrete situation, but a type of related situations. As such, the contextual configuration instantiates through a multiplicity of instances of related types which can be classified by specific values for a particular purpose. Applied to mathematical learning processes, this means that the contextual configuration of specific, similar situations is characterized by the inclusion of recurring elements or structures. Thus, the introduction to a mathematical problem differs from the solving of the task and each sequence has a set of possibilities for the realization of the register variables.

### Theoretical model and research question of LIMiT

For mathematical tasks, as a standard mathematical classroom situation, the same conclusions apply to contextual configurations. A mathematical task is contextualized with a textual structure which forms the textual basis of a mathematical task. In addition to the textual structures, there are additional activities that determine the contextual configurations in the process of solving a task, including receptive processes such as extracting information and productive processes such as creating a solution. However, the textual basis of mathematical tasks forms the initial structure of mathematical problems which can be interpreted as

particularly crucial for the further processes of problem solving. The starting point of the study is the analysis of textual configurations of mathematical tasks and the interpretation of the specific values for field, mode and tenor, based on a selection of grammatical and lexical features as seen in Figure 1. The model lies in terms of the cline of instantiation between the system pole and the instance pole. Considering the fact that registers vary in lexical and grammatical structures in particular, and this variation may present difficulties for learners, textual structures should be analyzed in the project. This model is preliminary in the way that it serves to illustrate the empirical analysis. For the project, a further extension of this model based on the metafunctions *ideational*, *interpersonal* and *textual function*. The textual configurations will be analyzed, and the following questions emerge: Which textual configurations can be extracted from mathematical tasks? How can the extracted structures be interpreted?

**Figure 1: Theoretical model of LIMiT**

## Method

The empirical analysis was based on 348 tasks from nine different secondary-school textbooks for mathematics classrooms. The textbooks are designed for students aged between 10 and 16 years. For each task, 17 different lexical and grammatical features were determined. A part of the lexical and grammatical features was quantified by expert ratings, such as mathematical terms, other parts of the data was quantified using corpus analysis, such as determining the frequency of words in a comparable corpus to determine the rarely used words (Michalke, Brown, Mirisola, Brulet, & Hauser, 2017). The selection of the lexical and grammatical features was made because of their relevance in the literature. The findings on difficulty-generating traits indicate that there are particular difficulties, especially in vocabulary, the presence of compressed structures but also in relational connections (Caplan & Waters, 1999; Kintsch, 2007; Leisen, 2013; Maier & Schweiger, 1999; Ozuru, Rowe, O'Reilly, & McNamara, 2008). Table 2 shows the chosen association between lexical and grammatical features and the typical situations of language use. Compared to Table 1 some changes were made. Thus, the category *relator* was added in *mode*, which can be regarded as essential for math problems, and

furthermore, the everyday situations were excluded from consideration for the empirical analysis, since there is no clear evidence regarding difficulty-generating traits.

Register variables	Field	Mode			Tenor	
Typical situations of language use	mathematical situations	spoken language	written language	relator	informal	formal
Lexical & grammatical features	mathematical terms, mathematical symbols, discontinuous text, numbers	compound s, lexical density, synonyms, passive voice	filler words, present perfect	prepositions, conjunctions	modal verbs	nominalization, propositional density, rarely used words, impersonal language

**Table 2: Selection and arrangement of lexical features**

## Results

The suitability of the correlation matrix for the use in a factor analysis was checked with the Bartlett test of sphericity, the test criteria have been met ( $\chi^2 = 454.31$ ,  $p < 0.001$ ). The KMO test for checking the adequacy of the data indicates only a moderate fit (overall MSA = 0.67). The moderate result can be explained by the fact that in the case of lexical and grammatical variables, a low share of common variance can be assumed. Accordingly, the present MSA may be considered sufficient for the adequacy of the data. Overall, a potential five-factor solution, can achieve a variance explanation of 45%, with a reduction of totally 70.6 % of the variables. The scree plot in Figure 2 shows the possible number of factors. To select the number of factors, the parallel analysis, shown in Figure 2, was used. According to the parallel analysis, a choice of 5 factors is sufficient.

**Figure 2: Scree plot to determine the factor solutions**

Figure 3 and 4 presents the five-factor solution in different versions. Figure 3 shows the loadings of the variables for each factor. This figure illustrates the specific characteristics variation of the variable for each factor. To illustrate which are the central variables with high

loadings, the simplified factor diagram in Figure 4 is used. The figures illustrate that factor 5 and factor 3 have a simple structure, which means that on these factors only single variables have high loadings. For factor 5, the variable *mathematical symbols* has the highest loading. In addition to *mathematical symbols*, the variable *mathematical terms* have also a characteristic loading on factor 5. Small loadings on factor 5 also show *prepositions*, *numbers*, and *lexical density*. The second factor with a simple structure is factor 4. Particularly relevant variables for this factor are the *lexical density*, *rarely used words* with a high negative loading *numbers*.

Figure 3: Factor loading diagram

Figure 4: Simplified factor diagram

The remaining three factors have more complex structures. At factor 3, the three variables *synonyms*, *modal verbs* and *perfect* are the variables with the highest loadings. In addition to the three factors, mentioned in the simplified factor diagram, *lexical density*, and *numbers* are variables with characteristic loadings. Furthermore, as can be seen in Figure 3, *mathematical terms*, and *discontinuous text* have relevant high negative loadings. For Factor 2, the variables *compounds*, *passive constructions*, *lexical density* and *discontinuous text* loading high on this factor. Other loadings with characteristic loadings are *propositional density*, *nominalization*, and *modal verbs*. The results of Factor 1 show high loadings of seven variables. On this factor, *conjunctions*, *prepositions*, *impersonal language*, *nominalization*, *numbers*, *mathematical terms* and *filler words* are loading high.

## Interpretation

To interpret the results of an exploratory factor analysis, simple structures are the easiest way to choose appropriate names. However, in the present results of the explorative factor analysis,

three out of two factors do not show a simple structure, and the designation of the factors may be problematic. To simplify the problem, Table 3 is used to assign the different variables to the typical situations of language use. To name the factors, the variables with the highest loadings are considered and to which situation of the language use they can be assigned to.

The factor 5 is referred to *mathematical textual configurations* due to the high loadings of variables from typical *mathematical situations* of language usage. The variables from typical *formal* language situations load high on factor 4. This results in the naming *formal textual configuration* for factor 4. The term *informal written textual configuration* for factor 3 derives from the association of high loading variables from *informal* and *written* situations of language use. For factor 2, situations of *written* and *mathematical* use are central. However, it should be noted that the assignment applies only to *discontinuous text*. Accordingly, the term *written discontinuous textual configuration* for factor 2 is chosen. As expected, Factor 1 has the greatest variety of characteristic situation of language use. Here are *relational*, *mathematical* and *formal* situations of language use characteristic elements. Hence the term *formal relational mathematical textual configuration* was chosen.

In summary, there are five textual configurations due to the loadings and the variations of the variables on the different factors: *mathematical TC*, *formal TC*, *informal written TC*, *written discontinuous TC*, and *formal relational mathematical TC*.

## Outlook

The naming of the factors shown above are qualitatively further specified in the present project in more details by individual instances. This means that regression scores are calculated for the individual variables and extreme cases are used to allow a further qualitative specification of the factor names. However, this specification is not possible at this point due to the focus of the paper. Rather, this paper should show that lexical and grammatical variables can be reduced to factors on which each variable varies.

In summary, the SFL-theory shows potential to analyze linguistic difficulties of learners in mathematical classroom. With SFL theory, the patterns of variation in the empirical study can be explained theoretically and thus, it is possible to present relevant implications for teachers. Moreover, the analysis of language on an SFL-perspective is content specific and therefore, more concrete for mathematics classes and provides pedagogical accessibility. The factor analysis, as an empirical method, is useful to identify textual configurations, but also contextual configuration in general of mathematical tasks. As shown above five factors can be identified, which provides an approach, on the one hand, to evaluate the difficulties. On the other hand, on this basis, a model for language proficiency in mathematical classrooms can be developed and implications for the practice of teachers can be made. The analysis provides an approach to determine the difficulty for each factor. The next steps of the project LIMiT are the theory-based interpretation and designation of the five textual configurations of the mathematical task. This is to be followed by the use of a further empirical method to evaluate the difficulties. Based on the results, a conception of an empirical model of task difficulties in mathematics and the construction of a pedagogical model for language proficiency in mathematics classrooms will be carried out.

# Relations between school achievement and language abilities in mathematics classrooms

Aurélie Chesnais

University of Montpellier, France; aurelie.chesnais@umontpellier.fr

*My research aims at studying how school achievement is related to social background in mathematics classrooms. I am comparing two sessions held in two contrasted schools, by the same teacher on the same subject. The analyses show that the fact that some elements related to the language of mathematics are “transparent” to the teacher might explain the differentiation in students’ achievement. The discussion will show how this research, conducted in a French context, meets preoccupations of the international community of researchers, in particular about the characterization of mathematical language and the question of multilingualism.*

*Keywords: Teaching practices, learning inequalities, multilingualism.*

## Introduction

My research focuses on the social dimension of language in order to investigate how learning inequalities are produced inside mathematics classrooms. This meets some preoccupations of CERME researchers, but with a point of view built in the French didactic research context. Building on the seminal work of Bourdieu and Passeron in the sixties that drew attention to the correlation between school achievement and sociocultural background, sociologists in France assume a “relational hypothesis”, stating that “the production of learning inequalities results from a confrontation between the socio language and the socio cognitive dispositions of the students on the one hand, and the obscurity and the implicit character of school requisites on the other hand” (Bautier & Goigoux, 2004). This implicit character results from the fact that these requisites are “transparent” to teachers which renders them “invisible” to students (Rochex & Crinon, 2011). This implicitness, which is nevertheless a condition of learning (Erath & Prediger, 2015; Planas, Morgan, & Schütte, 2018) sometimes creates ‘misunderstandings’ (Rochex & Crinon, 2011) for students who don’t have the ‘keys’ to decode it.

Moreover, sociolinguists like Bernstein, or Lahire and Bautier in France established that among these requisites, the ones concerning linguistic competencies play a fundamental role in the production of learning inequalities. This concerns not only linguistic competencies, but also competencies related to uses of language (Bautier, 1995; Planas et al., 2018): in everyday life, language is mostly used to support action in a given situation, whereas in learning activities, language is used to reflect on the world, speculate on it and categorize it using concepts. Students are more or less familiar with these latter forms, according to their sociocultural background.

An open question that interests researchers in mathematics education is trying to understand how the learning and teaching process within the classroom produces these learning inequalities, when specific knowledge is at stake (here, mathematics). Investigating this question supposes to identify, among the features of the language of mathematics and mathematics education (Pimm, 2004), linguistic competencies that might be unequally mastered by students, and the way they interfere in

the teaching and learning process in classrooms. The issue here is also to be able to consider alternatives especially to provide resources to support new teaching practices, in order to contribute to reducing learning inequalities by fostering every student's learning.

In this study, I considered the way language issues are handled in mathematics classrooms and the potential effects on learning outcomes in relation to students' sociocultural background. In this paper, I compare lessons held in two contrasted schools, one of which was situated in a 'disadvantaged' area, while the other school was not. The lessons were given by the same teacher on the same mathematics topic. Our analyses of the lessons aim at pointing out how differences in what occurs might induce differentiated learning for the students in the two classes; in particular, I try to understand the role played by linguistic competencies in these differences.

After presenting the theoretical framework and my methodology, I am presenting the preliminary analysis of the knowledge at hand, and of the tasks students are working on, during the observed sessions. I shall particularly stress linguistic issues. In the third part, I will present the results of the analyses.

### **Theoretical framework and methodological implications**

My theoretical framework is based on Activity theory adapted to mathematics teaching and learning in a school context (Robert & Rogalski, 2005; Vandebrouck, 2013). The main hypothesis is that learning results from students' activity which results (mainly) from the tasks the teacher chooses for students and the way s/he implements them in the class. Learning is defined as conceptualising. Conceptualization (as a product) of a specific piece of knowledge is characterized by three aspects, namely: the 'availability' of the knowledge to solve tasks in which it is relevant, its integration in the network of prior knowledge, and the use of associated 'signs' (in particular linguistic ones). Conceptualisation results from opportunities to use this piece of knowledge in various tasks, with various "adaptations" in the activity to solve the tasks<sup>1</sup>. From a Vygotskian perspective, managing specific linguistic signs - in particular verbal language - is an integral part of conceptualising, and the use of signs and the availability of a piece of knowledge to solve tasks develop dialectically. Our hypothesis on the role of the teacher in this process, resulting from the combination of Vygotskian and Piagetian ideas (Rogalski, in Vandebrouck, 2013), is that the teacher has to foster the activity of students to solve mathematical tasks, but s/he should also ensure that the solving of tasks actively supports opportunities for conceptualising. Interactions in classroom are then considered as potential opportunities for students' conceptualising but also as traces of how students interpret the mathematical and classroom norms (Planas & al., 2018).

The collected data consists of videos of the sessions about the notion of angles in two different classrooms of the first year of secondary school (6<sup>th</sup> grade) in two different schools: one which is situated in a disadvantaged area and one which is not. I shall respectively call them class 1 and class 2. In the two classrooms, the teacher, 'Mathew', is the same one and he is the regular teacher of both

---

<sup>1</sup> Robert, in Vandebrouck 2013, identified seven types of adaptations including the fact of mixing different pieces of knowledge or having to establish a procedure with several steps.

classes. Mathew explained in an interview that he sees no reason to make differences between the tasks he chooses for students of the two schools because his choice is made based on the coherence between the task and the aimed knowledge.

In the following section, I first explain the learning issues related to the mathematical content at stake (including official instructions), particularly stressing linguistic issues. I then describe the tasks set by Mathew to his students, predicting the possible activities that students might develop when completing them. Following this, I analyse the implementation of the tasks in the classroom. Using video-recordings, transcripts and in-situ observations (especially of the tracks of students' activity - what they do or say), I characterize students' activities as precisely as possible. Analysis of the videos also includes identifying what the teacher does or says and how it impacts directly on students' activity, but also the transformation of students' activity into learning.

## **Analysis of the mathematics at stake in the classroom sessions**

### **Preliminary study of mathematical contents**

In France, official instructions recommend to introduce the notion of right angle in grades 1 to 3 when pupils learn to distinguish between different geometric shapes (triangle, square ...), but the general angle concept is introduced in grades 4-5. In grades 4-5, pupils learn how to compare angles (by superimposing one on the other) and how to reproduce a given angle using a template of it on tracing paper. They discover the different types of angles (acute, right or obtuse angles), and they use a set square to validate visual estimations.

In 6<sup>th</sup> grade, students are still supposed to deepen their understanding of angle as an attribute, but the main teaching objective is learning how to use a protractor to measure angles and to construct an angle with a given measure. Moreover, the objects of geometry are supposed to change progressively, from drawings to theoretical objects, from the end of primary school to the end of lower secondary school. At the end of primary school, conceptualising of elementary geometrical figures is then still in progress: students are expected to know, in particular, about squares and right, isosceles and equilateral triangles and they can use instruments to confirm that a given figure is one of them, checking right angles using a set square and checking the equality of sides' lengths using a ruler. However, this does not guarantee that these figures are already fully conceptualised. In particular, students may know about squares and equilateral triangles, but do not necessarily conceptualise “the” square or “the” equilateral triangle as a figural concept. In particular, considering elementary geometrical figures as concepts eliminates the ideas of position and orientation in space, thickness and particularly size: the concept of square represents any square whichever dimensions it has. Indeed, what discriminates forms is angles, which is the element which is invariant under similitudes.

Thus, a crucial linguistic issue is to be able to discriminate between “a” square, “the” square, “all” squares or “any” square<sup>2</sup>. These terms may be used correctly unconsciously by experts, but carefully considering these variations appears to be fundamental when it comes to mathematics learning and teaching. Following Vygotsky, it may be assumed that a reasoned use of these determiners constitutes

---

<sup>2</sup> The same distinctions also exist in French: “un carré”, “le carré”, “tous les carrés”, “n'importe quel carré”.

a tool to foster the conceptualising of elementary geometrical figures. It also constitutes an indication of this conceptualisation when it is used by students. However, discriminating between these uses is complicated by the fact that the determinant “the” could either be used to refer to the concept, in its generic sense (“the square is a figure which angles are all right ones”), but also to refer to a specific object, in its deictic use (“look at *the* square we draw on the board”). Note that in French, unlike in English, the determiner used to signify singular or plural is not the same and the adjective also agrees with the noun (“the equilateral triangle” translates as “le triangle équilatéral”, whereas “the equilateral triangles” translates as “les triangles équilatéraux”).

### Analysis of the tasks

During the two sessions I observed, Mathew uses two tasks he found in a paper in a specialized journal<sup>3</sup>. The paper contained the description of a whole scenario about the teaching of angles which had been designed by a group of teachers. The idea of the project was to use a polyhedral box with faces that are squares, equilateral triangles and right isosceles ones. The first task of the scenario consisted of cutting models of the box with different scales to separate the faces and then group them to make ‘families’. Students are then asked to name and describe the families.

The second session was devoted to finding the measures of each angle of the faces, knowing that a right angle measures  $90^\circ$  (this value being announced by the teacher). I will particularly focus on the goal of establishing that the angles of the equilateral triangle(s) measure  $60^\circ$ . The expected activity of students is to put together three equilateral triangles (in adjacent positions) and observe that they obtain a “flat angle” (they are not supposed to know this expression) and that it corresponds to two right angles put together. They are then supposed to compute the double of 90 and divide the result by 3. This constitutes a complex reasoning in 6<sup>th</sup> grade, because there are a lot of subtasks and adaptations: for example, a lot of different knowledge is supposed to be used (about geometry, measure and numbers). Moreover, it relies (more or less implicitly) on the use of the property of additivity of adjacent angles’ measures. It also supposes to use the fact that angles of any equilateral triangle are equal and/or that all the angles of all equilateral triangles are equal. These properties are trivial for mathematicians (one can even consider that they define the equilateral triangle as a figure), but they are not necessarily known by 6<sup>th</sup> graders. At this age, a triangle still refers to a specific drawing and not necessarily to a figure as a concept; moreover, the notion of angle is not yet conceptualized either. In particular, students may not master the fact that angles are invariant under similitudes, i.e. that the measure of an angle does not depend on the length of its sides. Finally, equilateral triangles are generally characterized for students by the equality of their sides. Mathematically speaking, these properties concern THE equilateral triangle as a concept. The options offered to students then are either to first observe the fact that all three angles of a given equilateral triangle are equal, then apply the procedure and then generalize to all the equilateral triangles of any size, or to observe the fact that all the angles of all the equilateral triangles that they have are equal, whatever their size might be, and then apply the procedure. Both options seem to be difficult for 6<sup>th</sup>

---

<sup>3</sup> A journal that includes papers that present propositions for teaching (or for teacher training), coming either from researchers in mathematics education or from teachers.

graders. Completing the task and understanding what knowledge is at stake also implies considering the pieces of paper as representing geometrical figures and that some of them are the same figure, whichever size they are or even if they are not exactly superimposable because of the imprecision of cutting. Given all these considerations, these tasks might contribute to the conceptualizing of elementary geometrical figures as concepts, but it is not an explicit objective in the initial scenario, which is centered on angles.

## The two classroom sessions

At the end of the first session, families have been characterized in both classrooms by properties stated by the students: right angles and equal sides for the squares, one right angle and two equal sides for the right isosceles triangles; finally, about the equilateral triangles, students in both classes mentioned the equality of the sides, but only in class 2 did they mention the equality of angles.

## Differences in students' activities

Analyses show that in class 2, almost all students suggest solutions after 10 minutes. In class 1, Mathew observes that after 6 minutes students seem lost and he suggests putting some equilateral triangles together and observing if anything special happens. Only 5 students suggest answers (which remain partial) when the teacher stops individual work after 12 minutes. These differences suggest that students in the different classes were not equally able to complete the task: whereas students from class 2 do not seem to experience major difficulties completing it, the task seems very difficult for students from class 1. Analyzing the concluding phase in class 1 provides some clues to understand these differences. After showing that putting together three equilateral triangles gives a straight line (which is suggested by the most advanced students) Mathew tries to have students understand how this helps finding the measures of the angles. The addition of two right angles and the resulting  $180^\circ$  is mentioned, as well as the idea of dividing by 3 and the resulting value of  $60^\circ$ . After this, Mathew suggests writing down the whole solution on the board, but what appears is that some students' activity remains very far from what is expected, making me doubt their ability to seize the task as a real opportunity for learning. The following excerpt illustrates the misunderstanding lies:

- T: If I put the angles together, the angles of, of, which angles?  
 S1: of  $60^\circ$ .  
 T: each one measures  $60^\circ$ , but they are angles from which piece(s)<sup>4</sup>?  
 S2: equilateral triangle.  
 T: [writing on the board] if we put together three angles.  
 S1: the three angles of each triangle, one angle from each triangle.  
 S3: from each triangle.  
 T: from which triangle(s)? From any triangle?

---

<sup>4</sup> French language doesn't allow discriminating between singular and plural in the oral discourse.

- S1: the three over there [pointing at the board, where pieces are magnetically hung]  
 T: yes, but from which- Are they all three the same or not the same?  
 S1: they are identical.  
 S2: equilateral  
 T: [writing on the board] yes. If we put together three angles from equilateral triangles [...]

The question the teacher asks about “which piece(s)” and later “which triangle(s)” refers to the type of triangle and waits for “equilateral triangle(s)” as an answer but S1 refers to the material pieces: the discourse is not about the same objects. One might reasonably doubt that the students previously identified that all equilateral triangles have all their three angles that are equal (whereas, in class 2, students knew it from the first task). Note that, at the end, Mathew resolves the (theoretical) problem by mentioning the fact that all these triangles are “the same”, but it is probably not sufficient to make sure that all the students understand the reasoning.

The question that remains and is of great importance (in order to understand how why school achievement in mathematics is differentiated according to the sociocultural background of students) is to understand if these differences in students’ achievement could result from teacher’s choices, either because he does things differently or because some things he does similarly don’t have the same effect on all the students.

### **Differences in the teacher’s discourse in the two classes**

This excerpt suggests that the teacher has not understood what enables students, in class 1 to understand the reasoning. Moreover, the role of the property that all angles of all equilateral triangles are equal seems “transparent” to him: not only is it not explicitly stated when exposing the proof, but Mathew has students check that all the angles of all the equilateral triangles (all the pieces they have in their hands) are equal *only afterwards*.

I also compared the discourse of the teacher during the whole sessions. What appears as common between the two sessions is that Mathew alternates between saying “the equilateral triangles” and “the equilateral triangle”, attesting that these two expressions are equivalent for him. A difference that appears and seems important is that in class 2, he will earlier and more systematically use geometrical language: when presenting the task, he talks about “finding the measure of the angles of each figure”, whereas in class 1, the question is firstly formulated as “if I take this piece, the question is, this point, can I know how much it measures?” which is rapidly rephrased as “the aim is to say, for each piece, each angle, what is its measure?”. Vocabulary is more mathematical in the last formulation (for example he uses “angle”), and I conjecture that talking about the pieces instead of the figures does not help students to focus on the relevant objects. Moreover, it might explain why, at the end of the session (see excerpt above), some students still have not identified that what is at stake is the measure of the angles of the figure represented by the pieces of paper of the same family, and not the measure of the corner of each piece of paper.

## Discussion and conclusion

Differences between what happens in the two classrooms might explain some of the variability of students' activity and hence, learning. These differences seem to be related to elements introduced by either the teacher or the students, but without the teacher being aware of the possible impact of these differences (i.e., transparent elements). For example, mentioning "the" equilateral triangle might have implicitly helped some students to identify what was at stake but was not sufficient for others, especially in class 1. Moreover, the fact that the teacher mentions the pieces of paper in class 1 might have helped the students to start working, but jeopardized their identification of the learning issue.

Our study illustrates how the combination of socio linguistic and sociocultural characteristics of students on one hand and the transparency of some elements for the teacher on the other hand, appears to result in differentiating students' opportunities for learning in the two classes. The question that remains concerns the causes of the transparency for the teacher of elements that seem crucial to explain differentiation in students' achievement. I hypothesize that the issue of conceptualizing elementary geometrical figures is hidden behind language elements: the fact that "the equilateral triangles" becomes "the equilateral triangle" is very subtle. This is probably aggravated by the fact that elementary geometrical figures (and associated verbal language) are elements that are "naturalized" for teachers, like most of elementary mathematical knowledge, especially concerning mathematical logic (see Durand-Guerrier, 2013, or Chesnais, 2018).

Even if this research appears as closely related to the French context (by the fact that observations were conducted in French classrooms and concern French language but also that the research was conducted using French theories), it meets some crucial CERME's preoccupations for three reasons. First, following Pimm (1987), some features of mathematical language are common to diverse languages. Thus, considering the issue of the use of determiners in relation to quantification and conceptualization could constitute a relevant common object of research. Second, the transparency of issues related to mathematical language in classrooms is shared by teachers in all countries, and this hypothesis would be worth investigating. Third, the impact of the sociocultural background of students in school achievement could meet some preoccupations related to multilingualism. When multilingualism is related to poorer school achievement, it is often related to social backgrounds (in France and countries like South Africa as Phakeng, 2018, shows). Mixing the two preoccupations could help, in research about multilingualism, not to focus essentially on the mastery of language in terms of lexical and syntactical elements, but also on uses of language, which might be of greater importance to explain difficulties in school achievement (Bautier, 1995). This could explain why multilingualism seems to be an obstacle for students with lower sociocultural background whereas it appears as an advantage for students with upper sociocultural background. Even if the French educational system deliberately ignores multilingualism (except for new arrival students), French schools situated in disadvantaged areas often have a large number of students for whom French is not the first language. Considering the impact of multilingualism in mathematics achievement may allow enrich the approach of these students' difficulties and resources (Planas et al., 2018).

# Construction of mathematical discourses on generalization during group interaction

Judit Chico

Universitat Autònoma de Barcelona, Barcelona, Catalonia-Spain; [judit.chico@uab.cat](mailto:judit.chico@uab.cat)

*This study aims at analysing the impact of group interaction on the construction of learners' mathematical discourse on generalization in the classroom. Comparative and inductive analysis were applied to examine five group discussions with learners aged 15 and 16 involved in problem solving. I report the analyses of two segments of group discussion to illustrate how certain forms of interaction influence the production of mathematical language and the construction of discourses on generalization of patterns. Results show the positive effect of social interaction by minimizing the ambiguity of the language, connecting different linguistic expressions of a mathematical object and identifying the variables to construct a symbolic generalization.*

*Keywords: Group discussion, mathematical language, social interaction, generalization discourse.*

## Introduction

In Planas and Chico (2013), we reported the analysis of learning opportunities around the construction of algebraic thinking in the context of classroom group discussion. In that report, we established the bases for the study of the impact of social interaction on students' mathematical learning in a middle school classroom. On this occasion, I present the analysis of group discussion of another lesson of the same data corpus, with the purpose of arguing the impact of certain forms of interaction on the development of the language of mathematics in class. The mediation role of social interaction on classroom mathematical learning is key to social theories (Planas, 2014, 2018), but it is still necessary to expand and refine arguments about how this mediation occurs and with what effects for tasks focused on specific mathematical topics. Data, results and reflections in this report respond to the goal of identifying the impact of certain forms of interaction on the production of mathematical language and the construction of discourses on generalization processes.

In what follows I briefly present my theoretical views of social interaction, mathematical learning and discourse on generalization. Then I introduce the orientation of the methods applied in the research. From here, I comment on two lesson episodes to illustrate how certain forms of interaction influence students' mathematical discourses on generalization with specific implications for the development of languages of mathematics. I end with reflections on the relationship between social interaction and students' mathematical discourses on generalization.

## Social interaction, mathematical learning and discourses on generalization

Within the social theories of learning, I draw on the tradition of symbolic interactionism and socio-constructivism in mathematics education research (Krummheuer, 1995). Here social interaction is seen as a process in which individual actions are influenced by the interpretation of, and reaction to, the system of actions taking place in a setting. Specifically, my study is based on the tradition of micro-analyzing classroom discourses by interpreting empirical data in terms of participants' actions. The focus is on actions aimed at communicating and negotiating mathematical meanings articulated

in, and for the production of, mathematical discourse on generalization. A collective action is generated by linking participants' actions and depends on the individual meanings constructed in the interpretation process of the interaction (Blumer, 1969). If we add the vision of learning as recognition and use of meanings assignable to a discourse, we can say that while collective construction of the language of mathematics is produced, the bases for the individual mathematical learning of the participants in the interaction are established (Morgan, 2005). Accordingly, mathematical learning results from social interaction in contexts of use of the language of mathematics and the meanings associated with the appropriation of the school culture. From this perspective, I understand the notion of discourse as language in use with meanings depending on the context in which it occurs (Planas, 2018). Then, the conception of mathematical learning can be refined, seeing it as the recognition and use of meanings of a discourse by participating in it.

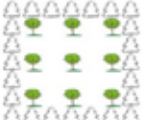

Mathematical learning understood as the development of the language of mathematics in a school culture requires the modification of student's discourse in those aspects that are far from the formality of the school mathematical discourse. Drouhard and Teppo (2004) claim that clear ordinary languages are a basic resource to facilitate the understanding of algebraic symbolism and syntax in problem-solving environments. The interpretive nature of assigning meaning to algebraic symbols and syntax requires substantial experiences with meaning-making activities around letters, words, and syntactic structures in ordinary school languages used to represent and discuss the problem to be solved (Planas & Chico, 2013). Difficulties in the recognition, understanding and symbolic representation of variables and their functional relationship endure over time for lower, upper secondary and university students (Ursini & Trigueros, 2006). Sorales and Kieran (2013) recommend classroom activities that allow connecting and developing syntactic and semantic levels to achieve a rich understanding of algebra. The problem-solving approach of generalization of patterns adopted in this research helps to develop both levels since it facilitates meanings for symbols from a functional perspective (Carraher & Schliemann, 2007).

As Radford (2010) claims, not all patterning activity leads to algebraic thinking in the same way as using symbolic language to express a pattern does not imply generalization reasoning. This is the case of inductive reasoning, frequently used by students, even if the inductive process can be expressed using symbolic language. Accordingly, I distinguish between inductive discourse originated by guessing strategies and generalization discourse that requires seeing something general in the particular. Moreover, algebraic generalization of patterns requires the use of symbols to reason about and to express a generalization (Kieran, 1989). If we see generalization of patterns as a route to algebra, there are different degrees of generalization (arithmetic, factual, contextual and symbolic) depending on the material form used to reason and to express the general (Radford, 2010). While an arithmetic generalization is based on "a local commonality observed in some figures, without being able to use this information to provide an expression of whatever term of the sequence" (Radford, 2010, p. 47), factual, contextual and symbolic generalization depend on the way a general rule is expressed, namely, using gestures and movements (factual), linguistic expressions (contextual) or algebraic language (symbolic).

## Research context and methods

A sequence of five lessons with five problems involving generalization of patterns was designed to facilitate algebraic thinking in a mathematics classroom with eight students aged 15 and 16. For each lesson, the teacher presented a problem and then the students discussed it in pairs while the teacher walked around the room. For the last thirty minutes, students were asked to discuss their approaches in a group and to examine and compare resolution strategies. The teacher acted as a facilitator of students' interactions. The students were used to pair work and group discussion. They were also used to problem-solving dynamics, to listening to each other, and to communicating their mathematical ideas. The problems included imaginable contexts outside mathematics and drawings of the first terms of a sequence. The questions were structured considering algebraic thinking: 1) concrete, considering small quantities; 2) semi-concrete, considering big quantities; and 3) abstract, using symbols (Carraher & Schliemann, 2007). Within the 5-problems sequence, the difficulty of a problem was also controlled by omitting the semi-concrete question and introducing a question that requires understanding of symbolic expressions as objects that can be manipulated (see Figure 1).

A farmer plants orange trees following a square shape and wants to plant pine trees all around. Here you can see the idea for 1-, 2-, and 3-row square.

1. How many orange and pine trees does the farmer need to plant for 5-row square?
2. For an  $n$ -row square, how many orange trees does he need? How many pine trees?
3. The main income for the farmer comes from selling oranges, and thus he wants to plant more orange than pine trees. Keeping the shape, is this possible?

Explain how you proceed for each case.

**Figure 1: Example of one of the problems in the study**

Data collection consisted of audio and video recordings of lessons. We began by transforming audio and video files into transcripts. First, I explored data of pair work and constructed a narrative detailing some aspects of students' interaction and generalization processes (Chico & Planas, 2011) to better understand the mathematical activity in group discussion. Regarding group discussion data, I began a process of comparative and inductive analysis (Glaser, 1969) to elaborate interactional codes. These codes mark students' actions informing about the continuation of mathematical content initiated in prior turns. In the interpretative process of codifying social interactions, two criteria were followed: i) attending to the closest context of interaction by differentiating the interaction between peers of a pair, ii) giving priority to the function of the language in relation to the mathematical content rather than to the linguistic form (see more detail in Chico, 2014). The interactional codes discussed in this report are: *Initiating* (new approach to the resolution), *Co-Initiating* (new approach to the resolution in pairs), *Co-Reflection* (on a resolution in pairs). To segment the transcript into episodes, I looked for changes in students' discourse on generalization, distinguishing between inductive discourse and arithmetic, factual, contextual or symbolic generalization discourses (Radford, 2010). The transcript of each episode was examined to complete the interactional codes with mathematical actions. From a linguistic perspective, I focused on mathematical actions that have an effect on the language used

such as word refinement, word (symbol)-meaning clarification, pattern linguistic (symbolic) expression or variable linguistic (symbolic) expression. At this point I had episodes characterized with interactional codes and mathematical actions. It took time to search for relationships between interactional codes and mathematical actions and regularities among the episodes. According to my goals, I looked for regularities of mathematical actions involved in a particular type of interaction. It gives information about the impact of social interaction on the production of mathematical language. Then, I looked for regularities in the combination of certain forms of interaction involved in changes in students' discourses on generalization. Hereunder, I present two episodes that represent what happened at different moments of the group discussions throughout the sessions.

### From inductive to symbolic generalization discourse

In the excerpt below, students discuss solutions for the second question of the problem in Figure 1. The interactional codes in this excerpt are *Initiating*, *Co-Initiating* and *Co-Reflection*. *Initiating* [1] and *Co-Initiating* [2-9] refer to the introduction of a resolution in the group discussion but while the first code is an individual action the second code refers to consecutive actions articulated by the peers of a pair to explain a new resolution. This is also the case of *Co-Reflection* [10-13], which indicates a reflection produced in and by pair interaction during group discussion.

- 1 Irene: We have used a rule of three, if for one row there are eight pine trees, for  $n$  there will be  $x$  orange trees. Oh! What a mess!  $x$  pine trees.
- 2 Gabriel: We have found directly that if we multiply eight times the number of rows it gives us the number of fir trees.
- 3 Jose: Of pine trees.
- 4 Gabriel: That's it. Of pine trees. First we have seen this observing the first and the second case. And then we have seen why.
- 5 Jose: Yes. Later we have seen why. We have seen that multiplying times two the number of rows, we have the number of pine trees that make a side of the square, this one. But not one. We already count one as being from the other.
- 6 Gabriel: The one on the corner.
- 7 Jose: Minus the one on the corner that we already count for the other side. Then, if it has three rows, three times two are six, so that here there are six pine trees, here six more, here six more, and here another six. Therefore, the number of rows times two gives you the number on one side and then you multiply times four that are the sides of the square.
- 8 Gabriel: Then if you multiply  $2n$  times four it gives you  $8n$ , which is the  $x$ .
- 9 Jose: That it is what we had seen before and we did not know why.
- 10 Óscar: It is more direct, is the developed formula.
- 11 Irene: It is like a simplification of ours if you do it.
- 12 Óscar: Ok... Theirs is thoughtful, we have been trying.
- 13 Irene: This is true. Theirs has a reason to be. Ours just worked.

The excerpt starts when Irene introduces the algebraic expression [ $1/8 = n/x$ ] based on inductive reasoning co-constructed with Óscar during pair work. Gabriel reacts by exposing a generalization based on multiplicative reasoning co-constructed with Jose during pair time [2]. Jose interrupts

Gabriel to suggest the use of the word "pines"-written on the wording problem- instead of "first" [3] and Gabriel accepts the suggestion [4]. Later, Gabriel points out the meaning of "one", *the one on the corner* [6], that Jose validates by including this linguistic expression in his explanation [7]. Gabriel's first explanation is based on the linguistic expression of the general rule  $x=8n$ , expressing the letters by referring to their meaning in the context [2]. Then Jose explains the counting strategy underlying the general rule as a commonality that can be applied in all terms of the sequence [5]. To name the variables, both students use the expressions "the number of rows" and "the number of pines", that is, linguistic generic expressions that can be applied in whatever term you may want to consider [2, 5]. Jose continues his own explanation of the counting strategy, making gestures on the pattern drawing to show how the general rule works in a particular term of the sequence. Gabriel follows-up by expressing the counting strategy and the final general rule using symbolic language [8]. In short, Jose and Gabriel share the responsibility of constructing a comprehensible discourse about a symbolic generalization that they have negotiated. The communication between them helps to make more explicit the language used and to connect linguistic expressions with different degrees of formality of the same generalization.

By the end of the excerpt, the direct communication between Irene and Óscar produce *co-reflection* on their discourse on generalization. First, they recognize the equivalence between the two symbolic expressions of the general rule, appreciating the syntactic simplification of the symbolic expression constructed by Gabriel and Jose [10-11]. Then, they reflect on their discourse as opposed to Gabriel and Jose's [12-13]. Although both pairs find and explain a general rule to solve the problem and use symbolic language to represent it, the heuristics of their discourse on generalization are different. Irene and Óscar's discourse is based on an inductive reasoning and using a trial and error strategy, they propose to apply a rule of three in a few particular cases. Gabriel and Jose's discourse points out what seems to be general in the common features of the given drawings. Irene and Óscar value the generalization discourse over the inductive because the generalization is "thoughtful" or "has a reason to be" and the inductive "just worked" by "trying" [12-13]. This suggests a qualitative modification of Irene and Óscar's discourse on the meaning of generalization mediated by the discourse constructed in the interaction between Jose and Gabriel.

### **From arithmetic to symbolic generalization discourse**

In the second excerpt the conversation is focused on another resolution to the second question of the problem in Figure 1. Cristina and Maria *co-initiate* the discussion by taking turns speaking to construct a generalization developed together during pair work [14-18]. Maria explains the meaning of the linguistic expression "the result" used by Cristina in the previous intervention [15-16]. This student validates and tests in case 5 what was said by Maria, who also incorporates the mathematical information given by Cristina [15]. Finally, Cristina synthesizes and orders the mathematical information of the previous turns to explain a counting strategy that depends on visual perception and does not contemplate the functional relationship between variables [18]. Thus, the interaction between these two students has a positive effect on the cohesion of the discourse that makes Cristina's explanation more comprehensible. The introduction of this approach in group discussion and the implicit request for help by Cristina [18] focus the subsequent conversation on the representation of this generalization in a symbolic language. This action was coded as *Requesting*. This code is a key

and repeated action that refers to the demand for clarification or help regarding an exposed mathematical reasoning. Gabriel and Irene request clarifications that lead to connecting the perceptual dependence of the counting strategy with the lack of references to the independent variable in the context [21-22]. Cristina implicitly asks for help in [23] and Irene identifies the independent variable [24], which is crucial to represent Cristina's resolution in a symbolic language. Irene connects the linguistic expression of the variable, "the rows", with the symbolic expression,  $n$ . Then Jose refers to the algebraic expression  $2n$  used in his resolution to represent the pine trees on one side minus one (see the previous excerpt) [25]. Although he does not explain the meaning of  $2n$  in the context of the problem, Maria represents the counting strategy in a symbolic language [26].

- 14 Cristina: I said, if you multiplied... you subtracted four from the result, the ones on the corners... I don't know...
- 15 Maria: You count one more in each side, the one on the corner. If there are four sides, four vertices...
- 16 Cristina: That is it! Four times eleven... adding the two corners in each side...
- 17 Maria: You add all and then subtract four, the ones on the corners.
- 18 Cristina: What you do is, from every side you count how many pine trees there are with the two corners. Then you multiply by four and then you must subtract four because you have counted the corners twice. But I am not able to write it down.
- 19 Óscar: Like in a formula?
- 20 Cristina: Yes.
- 21 Gabriel: But the number of sides, I mean, the number of pine trees, you cannot know it, right?
- 22 Irene: That's right, how could you know the number of pine trees if you do not have a drawing of it?
- 23 Cristina: But you guys knew it, right?
- 24 Irene: Sure! With the rows. The  $n$ .
- 25 Jose: Right with the rows, it is  $2n$ .
- 26 Maria: Then it will be  $2n$ . No!  $2n$  plus one, we multiply all times four and then we subtract the four vertices.
- 27 Cristina: And that is the number of pine trees, right? That is what we weren't able to do. We didn't find the relationship which holds, we have been trying, but we haven't found it.
- 28 Maria: Because this was the number of rows, not the number of orange trees... We haven't done it with the number of rows.
- 29 Cristina: Right, because of that we didn't find that those 11 were the  $2n$  plus one.

The excerpt finishes with *co-reflection* between Cristina and Maria on their discourse [26-29]. Cristina's initial discourse points to what is general in the particular. It can be said that it is a discourse about generalizing in the mathematics classroom, but not so much about generalizing algebraically. The development of algebraic thinking through the generalization of patterns implies representing the general case through the language of algebra in order to be able to later use a symbolic expression as a structural object (Kieran, 1989). This step is not trivial and involves identifying and representing variables symbolically as well as thinking about algebraic generalization as a functional relationship.

The modification of Cristina and Maria's discourse lies not only in the use of symbolic language to express a pattern, but in the recognition of the need to identify which are the variables to represent a functional relationship.

## Discussion

I have shown changes in students' mathematical languages along with the interactions involved in co-construction of processes of generalization. Results indicate that some forms of interaction have a special impact on the development of languages of mathematics and students' mathematical discourse on generalization. This is the case of *Co-Initiating*. The direct communication between students who were involved in the co-construction of a resolution have a positive effect on the explicitness of the students' language used and the cohesion of the discourse on generalization constructed. Peers of a pair share the responsibility to produce a comprehensible discourse to explain a resolution to the rest of the group. Students respond to, and build upon, the peer mathematical contributions in some appropriate way according to the classroom culture. Linguistic expressions with different degrees of formality to represent the same mathematical object are connected in the discourse co-produced by a pair in the group discussion. This fact mediates in discourse changes on generalization of other students as it was argued in the first excerpt. *Requesting* is also crucial to achieve changes in discourses on generalization. In the second excerpt, the identification along with the linguistic and symbolic expressions of the independent variable is influenced by *Requesting* and helps Maria and Cristina to move from arithmetic generalization to symbolic generalization discourse. These qualitative changes on generalization discourses are reflected again in the communication between students who were working together during pair time after they confront other discourses. Although these conversations have a private nature and are addressed to specific interlocutors, they are publicly produced and constitute a learning opportunity for the whole group. Under the assumption that the form of the students' participation in the classroom is determinant to mathematical learning, the role of the pair in the group has an important impact in the production of school mathematical languages used to construct discourses on generalization. Restructuring and connecting mathematical meanings in the group discussion represents a learning opportunity for all participants who, regardless of their participation in the construction of the certain discourse, are potential receivers of the mathematical information and are susceptible to experience conceptual changes on generalization.

# Metacognitive and discursive activities – an intellectual kernel of classroom discussions in learning mathematics

Elmar Cohors-Fresenborg

University of Osnabrueck, Department of Mathematics, Osnabrueck, Germany; cohors@uos.de

*Keywords: Classroom discussions, instructional quality, metacognition.*

## Theoretical background

Although metacognition is widely regarded as a promoter of sustainable learning processes (Dignath & Büttner, 2009), little is known about the implementation of metacognition and the mode of its functioning in classroom communications (Lingel, Neuenhaus, Artelt, & Schneider, 2014). When metacognition during classroom discussions is in the scope of interest, its conceptualization must refer to a broader scope of activities than in the case of problem solving. It cannot be restricted to metacognitive processes understood as cognition about one's own or others cognition, but should take into account also cognition about the inputs, subjects and results of cognition (calculation, verbal or written information, argumentations, questions). According to this conceptualization, the objectives of metacognition in learning mathematics are, for example, to *plan* the use of mathematical tools, methods, and representations to justify an argumentation or to explain an idea; to *control and evaluate* the accurateness of argumentations, the adequateness of external (e.g. formal) or internal representations of mathematical concepts, the correctness of the use of tools and procedures; to *reflect* on the ways of reasoning, defining or proving, and on similarities and differences in conceptions and arguments. The learning process in a class can lead to a deep understanding of concepts, representations and tools only if the planning, monitoring and reflection related to them are elaborated, take students' ways of thinking into consideration, and build a coherent discourse. Therefore, the class discussion must feature discursivity. *Discursivity* means activities carried out to support the coherence and precision of a discussion. On the contrary, *negative discursivity* means activities with a negative influence on understanding what is meant (Cohors-Fresenborg & Kaune, 2007).

## A rating system for evaluating metacognitive-discursive instructional quality

During the last three years<sup>1</sup>, we worked on the design of a rating system for evaluating metacognitive-discursive instructional quality in different school subjects. The rating procedure consists of two levels: first an extended version of the *category system* developed by Cohors-Fresenborg and Kaune (2007) is used to categorize metacognitive and discursive activities in students' and teacher's utterances; then, seven high inference *rating scales* are used for a global rating of the instructional quality of these activities in the given lesson (Nowińska, 2016). Each scale consists of an item (guiding question) focusing rater's attention on aspects to be evaluated, and of 3-5 answers describing in detail how these aspects are reflected in the discussion. The two-level rating procedure was tested and evaluated in the DFG-project, based on 24 videotaped lessons (6 teachers/classes à 4 lessons, grade 6 and 7). For 6 out of 7 rating scales, the generalizability studies indicate a high inter-rater reliability and a

---

<sup>1</sup> A research project supported by the DFG (German Science Foundation) under the reference CO 96/8-1.

relatively high stability of the evaluated aspects across lessons (g-coefficients  $>0.78$ ); only 3 lessons per class/teacher would be needed to get reliable and generalizable (over the lessons) assessments of the 6 aspects of the instructional quality (Nowińska & Praetorius, 2017).

### Some Insights from the Qualitative Lessons Analysis

When analyzing lessons an interesting type was observed in the case of some teachers/classes: there are many metacognitive, discursive, and only few negative discursive activities; but the class discussions are only on the surface of the underlying problems. If the mathematical content becomes a little bit more substantial, then the inability of the teacher and the students for elaborate metacognitive mathematical activities breaks through, and indicates the lack of metacognitive-discursive education of this class. Now, the classroom discussion shows a lot of metacognitive activities, but also lots of negative discursivity. Consequently, the global rating of the metacognitive-discursive instructional quality leads to many low marks: the metacognitive activities are not elaborate, do not build a coherent discourse, and therefore the students do not learn something substantial in this class. This observation is contrary to our hidden theory underlying the invention and use of the primary version of the category system (Cohors-Fresenborg & Kaune, 2007), as it was represented in this paper. The new observation can explain the low correlations between observed metacognition and learning achievements as sometimes reported in the literature. We assume that high ratings achieved with the two-level rating system are needed for a deep understanding of mathematics, and that such ratings can be regarded as an indicator for an intellectual kernel of classroom discussions in learning mathematics.

## Explorative study on language means for talking about enlarging figures in group work

Kirstin Erath

TU Dortmund University, Germany; kirstin.erath@math.tu-dortmund.de

*This paper presents a first step for designing language support for Grade 9 students working collaboratively on the topic of similarity, more precisely an adaptation of Brousseau's tangram task. The qualitative study identifies (topic specific) language means which students use for talking about their ideas on how to enlarge figures, combining geometrical and arithmetical ideas. Furthermore, a textbook analysis shows the target language that students should use and understand at the end of the teaching unit. The identified difference between both repertoires of identified language means calls for developing language-responsive teaching-learning arrangements in the future in which both language repertoires can be bridged systematically by macro-scaffolding trajectories.*

*Keywords: Language means, language repertoire of the learner, macro scaffolding, design research.*

### **Background: Need for supporting language means for rich discursive practices**

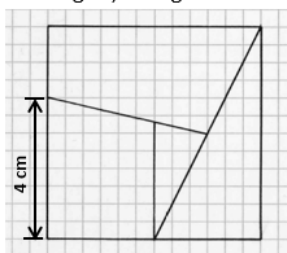

Students' participation is pointed out as crucial for learning mathematics by many researchers (e.g., Sfard, 2008) and is seen as “a process of enculturation into mathematical practices, including discursive practices (e.g., ways of explaining, proving, or defining mathematical concepts)” (Barwell, 2014, p. 332). Qualitative studies identify sequences of explaining and arguing as especially important for students' conceptual learning, in whole class discussions as well as in small group work (e.g., Mercer, Wegerif, & Dawes, 1999; Erath, 2017). However, especially for students with low language proficiency, participating in discursive practices that allow talking about conceptual knowledge is challenging (Erath, Prediger, Quasthoff, & Heller, 2018). Since language acts as a medium of thinking (Vygotsky, 1987) and following Interactional Discourse Analysis (Erath et al., 2018), this calls for supporting students in accomplishing demanding discursive practices in order to provide access to mathematical learning opportunities. Whereas in whole-class discussions, overcoming language-related obstacles can be spontaneously supported by the teacher, group work requires a prepared support when the teacher is absent. One dimension of prepared support refers to the establishment of norms about the ways students talk to each other, such as the “ground rules” proposed by Mercer (e.g., Mercer et al., 1999), emphasizing activities such as sharing relevant information and discussing alternatives. Students with low language proficiency often need additional support for accomplishing these norms, when lexical means or syntactical structures are required for explaining and arguing in the mathematical topic. Thus, referring to Gibbons' (2002) approach of macro scaffolding, these language means can be provided in prepared ways.

As Prediger & Zindel (2017) emphasize, the identification of mathematically relevant lexical and syntactical means for a specific mathematical topic is an *empirical task*; it can be conducted by analyzing textbooks and teaching-learning processes. Following the research approach of empirically identifying relevant language means, this study investigates a textbook and empirical video data for identifying the language means students initially use, the target language means, and for exploring possibilities of bridging between them.

## Research context: Exploring similarity in the Tangram Task

Especially teaching-learning arrangements that activate students' individual ideas and allow processes of solving problems and discovering mathematics have the potential to elicit vivid discussions about mathematics (e.g., Brousseau, 1997) and make demanding discursive practices necessary. For identifying students' initially used language means, the presented study focuses on the first task in a teaching unit on similarity using an adaption for four students of Brousseau's (1997, p. 177ff.) tangram task (see Figure 1; translated from German by the author). The task follows a more dynamic perspective on similarity since it leads to an understanding of similarity as the result of the process of enlarging figures true to scale: Hölzl (2018) terms approaches to similarity as *dynamic* if they relate to transformation geometry and as *static* if they refer to Euklid and define similar figures by identical angles and aspect ratios.

a) We would like to have a larger version of this figure.  
In doing so, a length of 4 cm should become a length of 7 cm.

(1) Each chooses a part of the figure.  
(2) Execute on the following steps in individual work:

- Draw the enlarged version on squared paper
- Cut the figure out

b) Check in your group if the enlarged pieces fit together again.  
What could be the reason?

**Figure 1: Task 1 of the teaching-learning arrangement of enlarging figures**

Thus, this paper empirically investigates students' initial language means in group work related to a task on enlarging figures true to scale and compares this repertoire to the target language means as identified in a widely used textbook by following these two research questions:

RQ1: Which language means can be identified in students' talk and in textbooks?

RQ2: Do some of these means have the potential to bridge between the identified repertoires?

## Methods: Qualitative analysis of students' interactions solving the tangram task

The presented analysis is part of the larger project MAGENTA that is conducted in the tradition of design research (Gravemeijer & Cobb, 2006). It aims at developing a language-responsive teaching-learning arrangement for the topic of similarity in German Grade 9 classrooms as well as building local theories on the students' learning processes.

## Methods of data collection

This paper reports research from the second cycle of collecting video data. The design experiments were conducted by two preservice mathematics teachers for their master thesis. Altogether, 6 groups of two or three students each (at the end of Grade 8 or 9; aged 14 to 16; all from the same lower

secondary school in an urban quarter in the Ruhr area) worked for 3 lessons on similarity. For all students, the design experiment was the first lesson on the mathematical concept of similarity. Following the idea of establishing ground rules, the importance of explaining and arguing and the way of working together was discussed with the students. For this paper, video data and written documents of the first task of the teaching-learning arrangement (Figure 1) were analyzed for investigating students' initial language means by making collections of the original expressions that were later on group by the used language means. The textbook analysis was conducted along the most sold textbook for comprehensive schools in North Rhine-Westphalia "mathe live" focusing on the pages introducing the topic of similarity until the summary (Böer et al., 2008, p. 20f.).

### Methods of data analysis

First, all sequences were collected in which students were working independently on Task 1, until students proceeded with another task or until the teacher started to intervene. Second, these sequences were transcribed and enriched by students' written products. The third step followed inductive category formation (Mayring, 2015) and coded all utterances by generalized versions of the language means that were used (i.e. language means using variables instead of numbers) in order to gain a repertoire of students' lexical and syntactical means. For the presented analysis, only categories related to talking about changing the sides of figures are considered due to space restrictions. The textbook analysis collected all language means in tasks related to enlarging figures and in the summary.

### Empirical results: language means for talking about enlarging figures

First, students' initially used language means and the target language means in textbooks are identified. Afterwards, the idea of bridging between these identified repertoires is discussed.

#### Students' language means for talking about enlarging figures

Task 1 proved highly suited for eliciting discursive group work, especially if students had different strategies for enlarging their parts, like in the group of Julian, Lara, and Nitika. Julian is the only student in the data of the presented research that utters the mathematically sound idea of *multiplying* each side with a constant factor that he calculates by using the rule of three (in German "Dreisatz" is a term for the rule of proportion) and that he furthermore connects with the idea of scale: "I don't know if this is correct now, but this 4 cm (...) this is like such a scale thing, right? So if 4 cm are 7 cm and 4 cm it is asked for two, the half, and the half of 7 is 3.5. Do you know what I mean?" (F1\_V1\_T1\_G1, line 53). All other students with multiplicative ideas think of enlarging a figure as *doubling* the lengths of the sides (which is only correct in special cases). Most students have *additive* ideas for enlarging figures. Hamsa, Jussuf, and Younis serve as an example for students talking about additive ideas, especially representing students struggling with expressing their mathematical ideas. The extract (F1\_F2\_V1\_T1\_G6; translated from German by the author) starts after the boys discover that their enlarged pieces do not fit together as a square:

- 72 Hamsa: [holds up Jussuf's enlarged piece] What's that? [all laughing]  
 73 Younis: This is much too small!  
 ...  
 78 Younis: Eh, mine is also a bit too large after all...

- 79 Hamsa: *[towards Jussuf]* Make new again!
- 80 Jussuf: Why? This is 7 cm, I think.
- 81 Hamsa well you have to- look, if 4 cm become 7 cm, you have to make larger by 3
- 82 Jussuf: There's from 4 to 7 after all...
- 83 Hamsa: You should do this one, right? *[points to the drawing in the task]* That are 6 cm here. They become 9. *[unclear]*
- 84 Jussuf: *[also points to the drawing]* I see, we should use from THESE data. I see. Well then. *[starts to draw]* [...]

Like all groups, the boys first describe quite broadly that somehow the size of the figures or some sides of them are too small or large (lines 73 to 78). Afterwards, Hamsa explains Jussuf how to additively enlarge the sides of the figure using the language means “if... (then)...” (line 81), “x cm become y cm” (lines 81 and 83), and “making larger by x” (line 81). The mathematically inadequate idea of enlarging the sides by adding 3 cm to all or some sides occurs in nearly all groups of the study. An overview on students' language means for talking about enlarging figures is printed in Table 1, sorted by the related mathematical ideas.

Language means	Examples from students' talk
<i>Students' language means for talking about additive ideas</i>	
to make x cm	Did you also make everything 3 cm, Leonie?
(to calculate) x plus y / plus x	Yes, I did everything plus 3. / So then you calculated 6 plus 3?
x become y	That are 6 cm here. They become 9.
x longer / larger / higher / more / ...	Yes, I though 3 cm longer. / Everything 3 cm larger. / Um, maybe it's just always 3 cm higher [...] to be 3 cm more?
x more / longer than	You have to be 3 cm more than true to scale. / You have to write 3 cm more than normal.
x on top	There was written that there are already 4 cm that you should enlarge on 7 cm in that I just calculate 3 cm on top.
to make larger by	look, if 4 cm become 7 cm, you have to make larger by 3
to enlarge on	There was written that there are already 4 cm that you should enlarge on 7 cm in that I just calculate 3 cm on top.
difference between x and y	I think 10.5, because 9 is only calculated plus 3. And that's just the difference between 4 and 7.
<i>Students' language means for talking about the idea of doubling</i>	
to take / make the double / to double	And eh it says 4 cm. And then I just took the double. Thus 8. And then this is enlarged. And quasi doubled.
<i>Students' language means for talking about multiplicative ideas</i>	
x corresponds to y / x are y	So, 4.5 are 7.875. So, this side is 4 cm long eh 4.5. But to begin with let's put away the 0.5. So, if we then calculate 0.5 corresponds to 0.875.
x times y	Just take the 6 cm and then 1.75 times 6. Simply just calculate times.
to calculate with the rule of three	Ehm, I did calculate with the rule of three for 1 cm 1.75 times 6, because it was 6 cm, that makes 10.5
on x cm	I have the rule of three, thus on 1 cm. To 3 cm because my side, well two were 3 cm, I think at least [...]
from x to ...	From 100 to .. And then from 1 times 3 and 1.75 times 3 are 5.25.

**Table 1: Students' language means for talking about enlarging figures identified in 6 groups**

Like Hamsa in line 81, students with additive ideas often initially use language means related to visual impressions of larger, more, higher, huger and related verbs. Furthermore, they often describe processes (instead of e.g. talking about characteristics or relations). Some groups also use the phrase “x cm become y cm” (like Hamsa in lines 81 and 83) that is also offered in the text of the task.

Another interesting inside refers to the line “x more/longer than” in Table 1 (not printed in the transcript but from this group): Jussuf’s utterance “You have to be 3 cm more than true to scale” (F1\_F2\_V1\_T1\_G6, line 249) combines two ideas in one sentence: the inadequate idea of additively enlarging the sides and the concept of scale which usually refers to the mathematically sound multiplicative idea of scaling with a magnification factor. Here, Jussuf seems to use “true to scale” for referring to the length in the original figure and/or for expressing that the shape is conserved. The phrase “true to scale” is taken up by the group and later on even used in their written general instruction for enlarging figures (Figure 2). But, since it is not discussed regarding its mathematical meaning, the term stays vague and is still used in connection with additive ideas.

~~Man muss 3cm länger als wie der Maßstab  
sein. Dann zeichnet man es auf  
dem Blatt. wenn man  
alles richtiggezeichnet hat  
man es sorgfältig aus. zum  
Schluss legt man die Figuren  
zusammen.~~

You have to be 3 cm longer than the scale. Then you draw it on the sheet. When you is all true to scale you cut it out thoroughly. At the end you put together the figures.

**Figure 2: General instruction on enlarging figures from Hamsa, Jussuf, and Younis**

The analysis of further language means related to multiplicative ideas reveals two important points. First, talking about the rule of three makes it necessary to talk about corresponding numbers, for example by the means “x corresponds to y” or “x are y” (see Table 1). These language means are relatable to a static perspective on similarity since they do not only describe a process but also relations. For example, the static perspective also talks about ‘constant length ratios of corresponding sides’. The expression “x corresponds to y” could also work with additive ideas but is not observed in this way in the analyzed data. Instead, only the expression “x becomes y” is identified which is very close to the formulation of the task and also has another meaning than “x corresponds to y”. Particularly, “x becomes y” (as a lot of the language means related to additive ideas) describes a process and not a relation and is thus more related to a dynamic perspective on similarity. Second, calculating with the rule of three makes it necessary to talk about calculating “on 1”. Mathematically this parallels the idea of calculating the magnification factor which is introduced in most German textbooks as the constant result of dividing the lengths of corresponding sides (see next Section).

### Language means identified in a textbook

The analyzed textbook starts with a page headed “Enlarging and Reducing” and introduces the new topic by referring to the dynamic perspective on similarity: several tasks ask students to draw enlarged/reduced pictures without giving any instruction. Task 5 is the only one talking about the process of reducing by “merging several boxes” (Böer et al., 2008, p. 20; see Figure 3 on the left side). The second page has the caption “Similarity” and starts with the questions “Which data does the drawer need to draw an enlarged version of the house? How do the line segments change, how do the angles change during enlarging?” next to a small and a larger drawing of a house, directly followed by the summary printed on the right side of Figure 3. Whereas the first question refers to a dynamic perspective on similarity, the second question is unclear but might be intended as a transition to the static perspective. In the summary, the first sentence refers to a dynamic perspective without talking about the corresponding processes, the remaining text to a static perspective.

5 Drawings in squared grid can be reduced by merging several small boxes. Merge four boxes each for reducing in your notebook.

### Übrigens

Der Maßstab  $k$  wird auch Ähnlichkeitsfaktor genannt. Er kann verschieden angegeben werden:  
 $3:4 = \frac{3}{4} = 0,75 = 75\%$

Wird eine Originalfigur maßstäblich vergrößert oder verkleinert, so sind Bildfigur und Originalfigur zueinander **ähnlich**. Das Längenverhältnis zwischen den Strecken der Bild- und der Originalfigur wird durch den **Maßstab  $k$**  festgelegt.

$$k = \frac{\text{Länge der Bildstrecke}}{\text{Länge der Originalstrecke}}$$

Jeder Winkel der Bildfigur ist genauso groß wie der entsprechende Winkel der Originalfigur.

Is an original figure enlarged or reduced true to scale, the picture figure and the original figure are similar to each other. The length ratio between the line segments of the picture and original figure is determined by the scale  $k$ . [...]

Each angle of the picture figure is just as big as the corresponding angle of the original figure.

**Figure 3: Extracts from the textbook (Böer et al., 2008, p. 20f.), translated by the author**

On the one hand, it was to be expected that the book does not offer a general instruction for enlarging figures on the first pages, since it follows the tradition of taking up students' ideas. Thus, except for "merging boxes", there are no language means for the dynamic perspective identified. On the other hand, the summary focuses on the static perspective on similarity with a strong emphasis on the concept of scale (most textbooks use the term 'magnification factor' which is here only mentioned as marginalia). The more mathematical perspective of this lack of transition between the perspectives will be discussed elsewhere. The analysis of language means shows, that "enlarging true to scale", "being similar to each other", "length ration" and "scale" (not as the concept scale but as the name for the quotient of length of the line segment in the picture and in the original) are language means that are of importance but not used in the tasks or texts before. The expression "corresponding" is used in this example only in connection to the angles. Other textbooks use this mean more prominent and especially for corresponding sides. A short review of more textbooks shows that starting with a dynamic perspective on similarity is quite common. After these first tasks of investigating how to enlarge figures, there is often a cut towards the summaries which are written from a static perspective on similarity, i.e. about "length ratios", "magnification factors", etc. which coincides with a change in the used language means from describing processes towards talking about relations. The comparison of students' initially used language means and the target language identified in textbooks shows that there is a gap: On the one side students talk about processes and visual impressions, especially if they refer to additive ideas. On the other side, textbooks initiate thinking and talking about this dynamic perspective on similarity (without offering related target language) but focus often exclusively on the static perspective in the printed summaries which is connected to talking about relations. Thus, even though using different tasks, the challenge of leading over from a more dynamic to a more static perspective on similarity can be identified in the textbook itself as well as by comparing the task from the project and the textbook.

### **Bridges from students' language means to the language means of textbooks**

Of course, it is not possible to compare students' oral language in the process of understanding with the written language of textbooks that display the already understood version of mathematics. Nevertheless, students need to be able to relate their language and the corresponding mathematical ideas from the phase of discovering mathematics with the counterpart from the textbook that is often the

basis for all other lesson phases (e.g., also as an idea in Gibbons 2002). Exploring possible bridges between students' initial language means and textbooks, three points appeared central: First, the textbook analysis revealed a cut between the use of the dynamic perspective in the first tasks and the use of the static perspective in the summaries which is paralleled in the used language means. Since the textbook does not offer language means for talking about the process of enlarging, it can be assumed that students in classrooms speak quite similar to the students in this study. This emphasizes the need of developing tasks that explicitly work on this transition of mathematical ideas along with supporting the corresponding language means in small groups or teacher guided whole-class discussion. Second, the notion of scale is used by Jussuf and Julian as well as in the presented textbook. But, this notion seems problematic since it is tied to a specific mathematical concept that needs to be understood in order to be used properly. Third and most important, the identification of language means used for talking about similarity in a dynamic perspective shows that students with additive ideas often use language means related to the visual change of sides and their language is very tied to describing processes. This also holds for the most cases in which students talk about their idea of doubling. In contrast, if students talk about the multiplicative idea, they tend not to use language means related to visual change. Especially Julian uses the language mean "x corresponds to y" which is close to "corresponding angles/sides" used in textbooks and also displays a more static perspective. Thus, the language means around "corresponding" can be identified as possible bridges between students' language and the language in textbooks since it can be used to describe parts of the process of enlarging as well as to talk about relations between features of figures. This could also hold for the expression "calculate on 1" which refers to the rule of three used in the process of enlarging but can be also interpreted as talking about the magnification factor which describes a relation.

## Conclusion and outlook

The study is limited in the small size of student groups that were observed. Thus, it is planned to extend the analysis to more groups and to enrich the data with more textbooks. Nevertheless, the presented research points to important directions: On the one hand, the study shows that students mainly talk about processes and refer to visually observable change, often staying a bit diffuse and not using mathematical wording (like adding, plus, etc.). On the other hand, textbooks often talk about similarity by means of characteristics and relations. This gap between students' initial language means and the target language parallels the difference between talking about similarity from a dynamic or static perspective. This highlights the need for developing a task that explicitly picks out this transition as a central theme and supports students by offering language related support. This especially holds for students with low language proficiency that are still acquiring language and discourse practices that allow talking about characteristics and relations of figures. The analysis points to two language means that have the potential to bridge between students initial language means and the target language: "x corresponds to y" and "calculate on 1" can be used for talking about similarity from a dynamic perspective and static perspective. Nevertheless, there is a need of further research for developing language-responsive teaching-learning arrangements in the future in which both language repertoires can be bridged systematically by macro-scaffolding trajectories as well as for teacher moves for supporting the group work and following whole class discussions.

# Young children's mathematising during free play with 'loose parts'

Marie Therese Farrugia

University of Malta, Faculty of Education, Malta; marie.t.farrugia@um.edu.mt

*'Learning through play' is an oft-quoted maxim for Early Years education. I was interested in investigating how free play with 'loose parts' (blocks, acorns, pebbles, etc.) might support children's experiences of mathematics. In this paper I discuss the first part of a study carried out with four 4-year-old children in Malta. The children were presented with various loose parts and allowed to play freely without adult intervention. I noted whether the children gave mathematical interpretations as they played; my main interest was numerical/quantitative interpretations. As a theoretical framework I drew on Vygotsky's theory of play and on the notion of 'mathematising' (Sfard), or participation in mathematical discourse. I considered this in terms of the relations set up by way of terminology (Walkerdine). My data showed that spontaneous mathematising during the free play was limited.*

*Keywords: Mathematics and play, early childhood education, mathematising; loose parts.*

## Introduction

As part of the recent Maltese National Curriculum Framework (Ministry for Education and Employment, 2012), the 'Early Years' (ages 3–7) has been recognised as a key period of education. The document emphasizes that the pedagogy to be used during this time should be distinguished from the more structured pedagogy used in the Primary years. In Malta, non-compulsory kindergarten education has been offered within State school settings since the mid-1970s, although, as Sollars (2018) explains, staff training, qualifications, recruitment and retention have posed challenges over the years. With the recent introduction of undergraduate training for kindergarten teachers, the hope is that over time, informal pedagogy will counter the established practices of formal literacy and numeracy sessions commonly carried out in kindergartens. My involvement in the new degree programme prompted me to carry out a study, in which I considered one type of play situation, namely invitations to engage with 'loose parts' (sets of items such as blocks, acorns, pebbles). My first research question was whether children would spontaneously give mathematical interpretations when playing freely with loose parts; I also asked if, and how, interpretations would be influenced when numbers were added to the sets of items available. A third question was how an adult's (myself) contributions could influence the children's apparent 'mathematising'. In this paper, I report on the first two questions.

## Mathematics and play

Björklund (2016) conjectures that there is hardly any early childhood educator or researcher who would not argue for the value of children's play. However, May (2016) reflects on what 'learning through play' means, highlighting that early years educators are pulled between two 'poles' (p. 21), namely construction and instruction. While 'construction' emphasizes more freedom for the child to discover and create meanings independently, 'instruction' assumes a greater role for the adult in the learning process. Several studies that have been carried out in Early Childhood settings focus on contexts wherein adult guidance is involved (e.g., Brandt, 2013; Sayers, Andrews & Björklund

Boistrup, 2016). It is less common to find studies on children playing freely. One notable exception is Helenius et al. (2016), who use free play situations to theorize what renders play ‘mathematical’. Helenius et al. (2016) suggest that play is rendered mathematical if it is creative, participatory and if it includes rule negotiation. They thus place social processes in the forefront of their analysis and used these criteria to describe episodes of 6-year-olds’ play as being mathematical or otherwise. They distinguish their method from a more common approach to associate the mathematics of young children with school topics such as number, geometry, pattern or measurement. I myself have taken the latter stance in my study for three reasons: First, I was interested in quantitative dimensions of reality (van Oers, 2014) from the perspective of the child; second, ‘Numbers’ are stressed in our kindergartens, and third, I wished to focus on the use of subject terminology to complement my research in primary classrooms (e.g., Farrugia, 2017).

Helenius, Johansson, Lange, Meaney and Wernberg (2016) explain that the acknowledgment of the importance of the educator in Early Childhood education has led to questions about the kind of learning that children gain when ‘left to their own devices’ (p. 7). Indeed, Lee and Ginsburg (2009) note that early childhood mathematics is broad in scope and doubt that much of it will emerge in free play. Similarly, Clements and Sarama (2018) argue that ‘mathematical centres’ (classroom areas set up with materials that might encourage mathematical tasks) might promote some incidental learning, but rarely build one mathematical idea on the next, which is a key characteristic of this content area. My interest in studying free play is founded on my knowledge that such periods are common in Maltese kindergartens. Sollars (2013, and works in progress discussed in personal communications) studied a large number of local early childhood settings, and has noted a common pattern of adult-guided structured activities interspersed with ‘free play’ at various times of the day. Structured activities (hence, ‘instruction’ time) include painting and crafts, storytelling, and also worksheets aimed to fulfil school and parental expectations for learning to recognize and write numbers and letters. Free play (presumably ‘construction’ time) might involve the home corner, table-top toys, coloured dough, wooden puzzles and sets of ‘loose parts’ (e.g., blocks, sticks, pebbles).

My interest in focusing on play with loose parts in particular derives from the assumption that such items, being open ended, are intended to invite interaction and creativity. With regard to mathematics, Tucker (2010) suggests that they offer opportunities for counting, sorting, pattern making, operations, investigations into weight and length, and problem solving. I am aware of only one project that (in part) focused on mathematics and loose parts. This was carried out by Novakowski (2015), who worked with teachers to provide children with ‘Reggio Approach’ inspired provocations. However, most of the activities were set up with an intention in mind (e.g., a pattern with gems is displayed, prompting the children to explore patterns of their own, or the children are challenged to try stacking five pebbles). It is not my intention to argue that this type of play is necessarily more/less suitable than other types of play for prompting mathematical interpretations. Rather, my intention is to offer an original focus by reflecting on young children’s mathematising during free play with loose parts.

## **Theoretical framework**

Vygotsky (1967) held that imaginary play had an enormous role in a child’s development, in that it is a transitional stage through which a child can ‘sever thought from an object’ (p. 12). The liberating

of thought and meaning from their origin in the perceptual field, provides the foundation for the further development of speech and its role in advanced forms of thinking. This liberation of meaning from object is facilitated by means of what Vygotsky referred to as ‘pivots’. If a child uses a stick as a horse, the stick acts as a pivot to transition to the child from a real situation to an imaginary one. Vygotsky (1978) further explains that when using a stick as a horse, the child retains the property of the thing, but changes its meaning. It is the meaning, in play, that now becomes the central point and objects are moved from a dominant to a subordinate position. Indeed, Vygotsky believes that a key characteristic of play is that it is a stage between, on one hand, the purely situational constraints of early childhood and, on the other hand, adult thought which can be totally free of real situation. Just as Vygotsky recognised play items as pivots for more abstract and imaginative thought, in this study I view the ‘loose parts’ as pivots that offer potential opportunities for mathematical interpretation.

Working within a Vygotskian perspective, van Oers (2010) explains that an unintentional, or spontaneous, action/utterance by a child may be taken as a cultural form [e.g. mathematics] and reacted to accordingly by an adult; in time, through participation in such interactions, the child him/herself may acknowledge the [mathematical] meaning of the adult reaction, and finally, of his/her own actions as well. The mastery of new language develops through communications with other people, even in play contexts (Van Oers, 2010). Sfard (2008) refers to the participation in mathematical discourse as ‘mathematising’. In her classic book, Walkerdine (1988) posits that a shift to mathematical discourse is a shift from one practice/system of signification (e.g. an ‘everyday’ activity) to another practice/system of signification (e.g. mathematics), wherein new relations are set up. For my analysis, I planned to focus on the children’s utterance of words that indicated a mathematical idea, and also on apparent relations expressed through these words. Relations may have been expressed by way of language alone, or with reference to the play items. I believed that the expression of such relations would allow me to discuss (a) whether the children engaged with mathematics ‘spontaneously’ in their play (first part of study); (b) if, and how, my prompts ‘pushed’ the children in the direction of considering the play items from a mathematical perspective (second part). My main interest was number and counting, although other ideas may also have been noted.

## Research design

The choice of school and classroom was opportunistic. I was acquainted professionally with the Head of School, who then put me in touch with a volunteer teacher who allowed me to work with her 4-year olds. I sat in the class a few times in order that the children and I become familiar with each other. Since the 14 children in the class came from varying language groups, the teacher used English as a lingua franca. This is a common language strategy used in Malta, where English is the country’s second language. The four children who participated in my study were chosen by the teacher such that they would feel comfortable playing together. Parental consent and the children’s own assent were also necessary. Mario and Sarah were Maltese, Dorina was Hungarian and Ling was Chinese. All four children understood English; they could also speak English, with Sarah and Dorina being the more fluent. During the study sessions, I used English, although switched to Maltese if Mario chose to speak to me in Maltese. Their teacher reported that they all ‘liked mathematics and numbers’.

Eight 30 minute video-recorded sessions were carried out in the school library. Sets of ‘loose parts’ were prepared in boxes/dishes and the children were free to choose items to play with; a selection of the following items were provided on various days: acorns, small tree slices, sea shells, plastic coloured blocks, plastic coloured connecting camels, white and black river pebbles, gemstones, coloured foam dice. Numerals in various forms were introduced in Session 5. My main interest was number/quantity, but I was open to note other mathematical ideas that might arise. The children generally played around a table, sometimes moving to other parts of the room. For the first five sessions, children played freely, with minimal interaction from my part. Although the intention was not to intervene at all, in practice I found that simply watching without saying a word was unnatural; some interaction was inevitable. However, for Sessions 6–8, I interacted much more, and with purpose, as they played. In this paper I report on the first part, Sessions 1 - 5.

Analysis of the data was done by viewing the videos and noting where ‘mathematical’ vocabulary was used by the children. Short transcripts were produced of these excerpts in order to trace interaction (for example, to document if, and how, a child’s comment was reacted to by the others).

## Results

The children played with the items eagerly. For much of the time each child was focused on their own task, albeit communicating with the others, and being influenced by the play going on around them. For example, if Dorina made a ‘necklace’ with connecting camels, the others picked up the idea and made their own necklaces, bracelets and crowns. At times Sarah and Ling played together. A lot of the play was imaginative and centred on the idea of birthday parties, an idea originated by Sarah. An element that persisted throughout all the sessions was making ‘cakes’ by filling the plastic dishes with pebbles and the other items. Pictures of children or monsters were sometimes placed in the dish to represent party guests; the table was sometimes decorated in various ways and the children sang ‘Jingle Bells’. The most popular items were the sea shells, gemstones and connecting camels. Figure 1 shows two cakes and a necklace.

**Figure 1: Examples of children’s play creations**

There were a number of comments relating to size and shape, and a high proportion of these were stated in the first session, when the children first saw the sets of items, for example “Oh! Tiny little shell!” (Dorina); “This is a pointy one” (Sarah); “This small one” (Ling). Not enough was said here for me to be able to conclude that the children were operating beyond an everyday use of qualitative descriptions (Walkerdine, 1988), although Mario did express direct comparison, a first step to the quantitative aspect of measurement (“Mine is going to be bigger than yours”). In relation to shape, Dorina once said that her camel arrangement was a rectangle, and Mario commented “it’s oval” in relation to a shell. Hence, they applied names of geometric shapes to their play items, even if the

labelling was imprecise. Occasions when *numbers* were mentioned were few. When the children first saw the monster pictures, and prompted by Dorina, they started commenting on the number of eyes (“One eye”, “two eyes” etc.); on two of the days, Dorina also selected monsters according to their eyes. In the first session, Ling pointed to the cameras saying “One, two.” At another point in the same session, Mario asked me why I had two cameras. These spontaneous uses of numbers were clear examples of quantification, and hence of these three children’s participation in the cultural practice of using numbers for expressing cardinality. It was interesting that quantity was alluded to more when a problem of limited number of each type of resource arose. Comments like “I don’t have enough of these” (Dorina), “But I need one of those!” (Mario) and other similar comments were heard, as children vied for the items they wanted/needed. The first time the problem arose this happened since we had limited space to work in, so I had to cut down on resources; then, the following day I limited the number of items purposely in order to confirm my observation. Mario and Sarah spontaneously indicated ‘emerging’ mathematical ideas relating to million as a large number, and half as part of a whole: “It was my birthday; it was a million birthdays” (Mario), “Hey Ling! You took half them!” (Sarah, referring to the gems) and “**Ghax jinkiser bil-half**” [**Because it will break with half**] (Mario, in relation to a delicate shell). On the other hand, I had included a set of foam dice to offer an opportunity for the children to focus on the dot arrangement, perhaps to subitise. However, the children used the dice as part of the cake decoration, or to construct a tower. Dorina mentioned that she had once had ‘one like this’ (a die), had lost it, and now had a new one. Although generally I was not intervening in the sessions, I pointed to the spots and asked Dorina if she knew what they were, to which she answered, “Yes, spots”. Thus she gave an everyday interpretation of the spot pattern, and did not spontaneously subitise.

On the fifth day I introduced numerals (1–10): a set of large red/blue/yellow plastic numbers, a set of magnetic numbers and cards with pictures of balloons printed on them. Dorina showed an interest in them immediately, crying: “Numbers!!!” She took magnetic numbers and laid them out in order on a metal sheet pointing to each one and naming them: “one, two, three ...” The relation between the positioning of the tangible numbers and the recitation of the names illustrated that Dorina could engage in the practice of counting using the one-to-one and stable order principles (Gelman & Gallistel, 1986). She proudly showed up the display to the others, but they showed no interest, continuing with their own activities. Dorina then moved on to making a necklace with the camels. Similarly, Mario started the session by looking through the large numbers, naming some of the them as he did, thus giving evidence that he could ‘name’ the items appropriately; however he very quickly lost interest and turned to the box of camels instead to make a crown and other things. Ling showed evidence of being familiar with the cultural practice of putting a number candle on a birthday cake: she placed a number 4 on her cake, stating “I’m four year”, then placed other different numbers on the other cakes. I consider this to be evidence of an ‘emerging’ mathematical idea, since although the symbol was used appropriately in relation with the ‘cake’, it is unlikely that such a young child would have a conception of the time measurement of ‘4 years’.

Other uses of the number items were non mathematical, for example as when Dorina grouped them by colour, placed them in different dishes and stated “I am making pies of the same colour”; Ling and Sarah used the magnetic numbers as they did the pebbles, acorns, etc., that is, to fill a dish to create

a cake. When I asked Ling why she had put ‘these new ones [items]’ on top of her cake, she answered “because this number cake”; in previous sessions she had made a ‘birthday cake’ and a ‘rainbow cake’. Sarah used the large plastic numbers as decorations around the cakes, as she had used the children/monster/balloon cards. At the end of the session, having exhausted all the items except the magnetic numbers, Ling and Sarah turned to these items and used them to ‘draw’ what they called a number castle (that is, a castle drawn with the numbers).

## Discussion and conclusion

Prior to the study, I had anticipated that the children might spontaneously engage with mathematics in general, and number in particular. This assumption was based partly on the fact that at school they were systematically learning the numbers and their values, and partly on research and pedagogy texts (for example, Seo & Ginsburg, 2004; Charlesworth, 2012 respectively) that mention how children ‘spontaneously’ engage with mathematical ideas. However, in my small study I noted limited spontaneous focus on ideas that I might classify as ‘mathematical’. That is, mathematical terminology was used only a little, and not necessarily in a way that implied mathematical relations (Walkerdine, 1988). In the absence of certain relations, one cannot conclude that the children were ‘mathematising’. Even when prompted with numbers, the children’s attention to the quantities related to these numbers was limited. Since I had seen large dice in the classroom, one with numerals and one with the spot pattern, I introduced the dice to prompt subitising, but these were used as blocks or decorations. Hence, following Helenius, Johansson, Lange, Meaney and Wernberg (2016) and others, I too query the amount of mathematics that children engage with when left to play freely, although it is worth noting that restricting the number of resources increased talk related to quantity/number. There was some evidence of ‘emerging’ mathematical ideas, such as when the children used discipline-related words in an approximate or referential manner. This is similar to when the children use grammar rules in an inappropriate way. Examples of the latter are when Ling said to Dorina “You broke-ed them” or Mario said “Ajma, subajji” [Ow, my finger]. In both cases the child was applying a general grammar rule (shown here underlined) which did not actually apply to the word being used. Still, as an adult I recognized the emergence of language rules that, presumably, the child was appropriating through social interaction over time. From the perspective of mathematising, ‘emergent mathematics’ might be viewed as the crossing of boundaries (Walkerdine, 1988) from one practice (everyday experiences and ways of expression) to another (school mathematics).

One possible explanation for the limited mathematising might be found in the children’s classroom experiences. The class teacher had explained that she targeted mathematics (mainly numbers) through daily routines (e.g. counting children present) and storytelling (e.g. counting the fruit the hungry caterpillar ate) and also through worksheets focusing on number recognition and quantities which were expected to be carried out. While the children were regularly given periods of free play (house corner, table top toys, puzzles, sets of loose parts and so on), the teacher admitted that during such time she did not interact with the children but tended to use the time to catch up with required paper work, to set up an activity, disinfect toys or to sit with individuals to help them through a worksheet (numbers / letters). It seems that the mathematics they were learning in the structured curriculum remained distinct from their play. Another reason may have been that from the children’s perspective, there was no ‘need’ or interest to count items or to engage with the numbers provided in a

mathematical sense. Rather, the tasks of (mainly) making cakes and joining up camels took over the children's attention almost completely. Although the children initially admired the pebbles, etc. and the numbers, ultimately, the use of all items appeared to be subordinated to the main task of interest, e.g. filling a dish to make a cake, 'drawing' a picture and so on. This may have been compounded by the fact that many of the items provided were novel and caught the children's attention/imagination.

Vygotsky (1967) has written about the development of abstract thought through free play; he theorises how meaning becomes central, while objects themselves are moved to a subordinate position. There is still much to be done in exploring the transition from a play situation to one where play items are given an abstract 'mathematical' interpretation. That is, focusing on the numerical/quantitative aspect rather than, for example, on the item's potential use in the creation of a cake. In the second part of my study, I made a systematic attempt at using the play items as 'pivots' for mathematising. My initial analysis (still to be reported) supports the argument that purposeful intervention can be effective for prompting a focus on mathematics. According to Walkerdine (1988), this focus involves creating new relations, even when using lexical elements already familiar from 'everyday' (hence different) experiences. In the context of free play - where children rightly assume a freedom to play as they please - the process is a challenging one.

## High school teachers' evaluation of argumentative texts in mathematics

Giovannina Albano<sup>1</sup>, Cristina Coppola<sup>1</sup> and Pier Luigi Ferrari<sup>2</sup>

<sup>2</sup>Università del Piemonte Orientale; [pierluigi.ferrari@uniupo.it](mailto:pierluigi.ferrari@uniupo.it)

*The goal of this paper is to start an investigation on how high school teachers evaluate students' argumentative texts. In particular, as an argumentation requires dealing with some mathematical content, to produce a verbal text, possibly equipped with diagrams and formulas, and to make clear the links between premises and conclusion, we are interested in finding out whether teachers focus on all of the three aspects or on one or two of them only. We have gathered the comments of 12 high school teachers on five argumentations written by university science students in order to justify their answers to a problem involving formulas and graphs.*

*Keywords: Argumentation, language, evaluation, teachers, mathematics education.*

### Introduction

The importance of argumentative practices in mathematics teaching at all levels has been increasingly highlighted in the last years. In the transition from high school to university these practices are especially important. This holds also for the mathematics classes for science undergraduates, as it is often necessary to teach some basic concepts to large numbers of first-year university students with assorted levels of competence and motivation, in a short span of time. In this context, it might happen that some students try to learn some content by heart or to solve problems through strategies not based on some interpretation of the meanings involved. The practice of asking for argumentations to explain and justify their solution procedures when dealing with mathematical problems has proved effective both to assess students' competence and to help them to adjust their learning processes. Still, a number of students seem not to be acquainted with argumentative practices, regard them as abnormal and cannot tell the difference between a correct and justified procedure and a correct but unjustified one. These remarks induce us to guess that there are some problems about the development of argumentative skills in high school. So we decided to start a study about how high school teachers interpret and assess argumentative text produced by students, in order to see which aspects are, in their opinion, relevant. Throughout the paper we use some terms (such as 'proof', 'argumentation', 'argument', 'explanation', 'justification') in a broad sense, without referring to some distinctions proposed in literature, such as, for example, Duval's distinction between proof and argumentation (2007), or Johnson's distinction between 'argumentation' and 'explanation' (2000), or the distinctions between 'argumentation' and 'argument' proposed in literature (e.g., Johnson, 2000, p. 105; Bermejo-Luque, 2011, p. 68). We regard the proof of a theorem, as well as the justification of a resolution procedure of a mathematical problem, as texts that, in some way, describe and make

explicit instances of the semantic relation of *logical consequence*<sup>1</sup>. We shall try to make this point clear in the a priori analysis.

## Theoretical framework

The evaluation of an argumentation involves at least three main aspects: the analysis of the ideas related to the semantic domain of the discourse, in our case mathematics; the linguistic analysis of the text produced and the analysis of how the links between the premises and the conclusion are made explicit. These three aspects are to some extent autonomous, since an argument might happen to be appropriate related to one or two of them and not to the other(s). As remarked by many authors, such as Bermejo-Luque (2011), an argument is, first of all, a piece of text. So language is to be regarded as a relevant factor in the analysis of arguments. We adopt a functional-linguistic perspective according to Halliday (1985) and Hasan (2005). This perspective fits well with frameworks assuming that language plays a major role in the development of thought, and also with a sociocultural, non-platonistic view of mathematics. In particular, we assume Hasan's description of the central role of verbal language (2005) and Halliday's definition of the three metafunctions of language, ideational, interpersonal and textual (1985). In short, the ideational metafunction is related to the representational meaning, i.e. what the text is about. The interpersonal metafunction is concerned with interactional meaning, i.e. what the text is doing as a verbal exchange between people. The textual metafunction regards the organization of the message, i.e., how the text relates to the surrounding discourse, and to the context of situation in which it is produced. We believe that in a context of communication like a classroom, all of these components are involved and so are to be taken into account. In particular, the textual metafunction is closely related to argumentation, since explaining the links between premises and conclusion requires a well-organized text. The debate on argumentation theory is widely complex and involves a number of stances. In our opinion both the specific features of the semantic domain of mathematics and the fact that an argumentation is essentially a text are to be taken into account.

## Goals

The main goal of this study is to begin to understand how high school teachers of different subjects evaluate the written argumentations produced by students, and in particular what weight they assign to each of the three aspects mentioned above, and how. This is important in order to reflect on the transition from a model of learning based on the acquisition of content only to a model aimed at developing the competencies required to take part in a discourse on such content. Arguing on a subject requires a different and somewhat deeper understanding of the subject itself.

More specifically, our main research question is: do the teachers involved also take into account the logical structure of the arguments they are evaluating (i.e., how the parts of the argumentative text are linked each other)?

## Methodology

We asked a group of 12 high school teachers of different subjects (9 Mathematics, 2 Philosophy, 1 Science) to evaluate the argumentations proposed by 5 first year science undergraduate students to

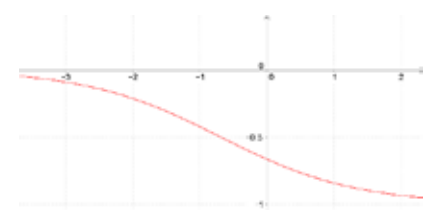

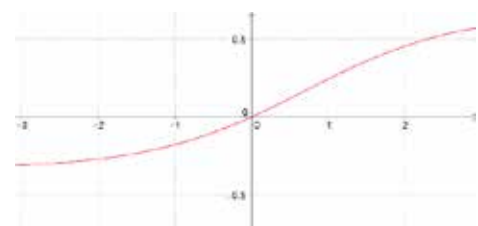

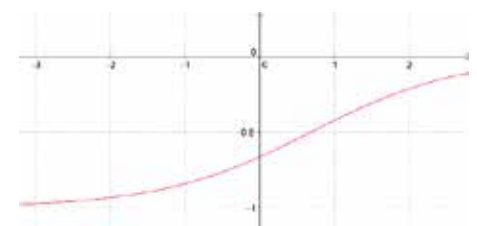

---

<sup>1</sup> A sentence *P* is a *logical consequence* of a set *G* of sentences if any interpretation satisfying all of the sentences of *G* satisfies *P* as well.

justify their answers to a problem administered during a tutorial session. The teachers were involved in a long-term in-service training course focused on transversal competences. We asked them to write down their evaluation of the arguments and any comments they felt appropriate. In particular we asked them to state if they regarded the arguments acceptable for students at the end of high school, with regard to mathematical correctness, linguistic adequacy and explicitation of the links between the parts of the argument. Afterwards we interviewed them. The aim of the interviews was not to elicit further information but to be sure of our interpretation of what they meant in their written evaluations, as it was possible that teachers of different subjects might use some words with different meanings. One example of such a word is ‘formal’ [‘formale’], which can be associated to a range of different meanings, such as ‘independent from content’ or ‘conformed to a given pattern’ or even ‘related to structure rather than to function’. The problem under discussion is shown below.

Let  $f$  be the function defined on real numbers by:  $f(x) = -\frac{2}{e^x + 2}$ . Among the following graphs one is associated to  $f$ . Mark it and explain in detail.

<p>A</p> 	<p>B</p> 
<p>C</p> 	<p>D</p> 

A good translation from one language to another, which is usually based on grammar, often succeeds in rendering the ideational meaning of a text. With interpersonal and textual meanings there are sometimes problems. In particular, the textual organization of Italian is quite different from English. For example, in the text of Student 1 some subjects are missing. In English this is both a grammatical and a textual error, whereas in Italian it is textually inappropriate but not grammatically wrong. In the translation, if we put the subjects, as we have been taught at school, we hide the textual inadequacy of the text, if we do not, we add a grammatical error (which affects the ideational meaning) to a text which was just textually inappropriate. So we have added the Italian original version.

Student 1: I exclude the graphs A and B because we have calculated  $f'(0)=2/9$  and  $2/9$  is the slope of the tangent line to  $f(x)$  in  $x_0$ . As is positive, the function is increasing, but in A and B we see that decreases  $\Rightarrow$  I exclude them. Moreover, doing the sign of the function  $-2/(e^x+2)>0$  we notice that the function is always negative, because of  $f'(0)=2/9$  he

minus in front of the function (otherwise positive). Then we exclude the graph *C*, since from 0 onwards it is positive. The choice then falls on graph *D*, correct.

[Escludo i grafici A e B poiché abbiamo calcolato  $\frac{2}{9}$  è la pendenza della retta tangente a  $f(x)$  in  $x_0$ . Essendo positiva la funzione è crescente, ma in A e B notiamo che decresce  $\Rightarrow$  li escludo. Inoltre facendo il segno della funzione  $- \frac{2}{(e^x+2)} > 0$  notiamo che la funzione è sempre negativa, per via del meno davanti alla funzione (altrimenti positiva). Allora possiamo escludere il grafico C, poiché da 0 in poi è positiva. La scelta ricade allora sul grafico D, corretto.]

Student 2: The exact graph is *D* since by computing  $f(0) = -\frac{2}{3}$  I found the point where the function cuts the y axis, that is  $-\frac{2}{3}$ . Furthermore, by computing  $f'(0) = \frac{2}{9}$  I see that the function in zero is increasing because the derivative in 0 is positive.

[Il grafico esatto è il *D* poiché calcolando  $f(0) = -\frac{2}{3}$  ho trovato il punto in cui la funzione interseca l'asse y cioè  $-\frac{2}{3}$ . Inoltre calcolando  $f'(0) = \frac{2}{9}$  noto che la funzione in zero è crescente poiché la derivata in zero è positiva.]

Student 3: Surely graph C does not correspond to  $f(x)$  as it passes through the origin. Graph A does not correspond to  $f(x)$  since it is decreasing in  $x=0$  whereas  $f'(0) = \frac{9}{2}$  which is positive, so  $f(x)$  for  $x=0$  is increasing. Graph B does not correspond to  $f(x)$  since it is decreasing in  $x=0$  whereas  $f'(0) = \frac{9}{2}$  which is positive, so  $f(x)$  for  $x=0$  is increasing. The graph that most likely represents  $f(x)$  is *D*.

[Il grafico C sicuramente non corrisponde a  $f(x)$  in quanto passa per l'origine. Il grafico A non corrisponde a  $f(x)$  in quanto è decrescente in  $x=0$  mentre  $f'(0) = \frac{9}{2}$  che è positivo quindi  $f(x)$  per  $x=0$  è crescente. Il grafico B non corrisponde a  $f(x)$  in quanto è decrescente per  $x=0$  mentre  $f'(0) = \frac{9}{2}$  che è positivo quindi  $f(x)$  per  $x=0$  è crescente. Il grafico che più probabilmente rappresenta  $f(x)$  è il *D*.]

Student 4: Graph C does not correspond to  $f$  as it passes through the origin. I know that in  $f'(0)$  the derivative is positive, so its function must be increasing in that point. In A and B this does not happen. So the graph of the function is letter *D*.

[Il grafico C non corrisponde a  $f$  in quanto passa per l'origine. So che in  $f'(0)$  la derivata è positiva, quindi la sua funzione deve essere crescente in quel punto. In A e B ciò non avviene. Quindi il grafico della funzione è la lettera *D*.]

Student 5: We exclude letter C at once since for  $x=0$  it passes through point  $(0; 0)$  while  $f(0) \neq 0$ . If we consider that  $f'(0) > 0$  holds, the function is increasing in 0 so I exclude letters A and B, as they represent functions decreasing in 0 and a differentiable function decreasing in a point has a non-positive derivative in that point.

[Escludiamo subito la lettera C perché per  $x=0$  passa nel punto  $(0; 0)$  mentre  $f(0) \neq 0$ . Considerando che vale  $f'(0) > 0$  la funzione  $f$  è crescente in 0 quindi escludo le lettere A e B, in quanto rappresentano funzioni decrescenti in 0 e una funzione derivabile decrescente in un punto ha la derivata non positiva in quel punto.]

## A priori analysis

Students are requested to find which graph out of a set of four corresponds to  $f$  and to justify their answer. Teachers are requested to evaluate those explanations. The relation linking the answer to the data is that of logical consequence: the fact that graph  $D$  corresponds to  $f$  is a logical consequence of the data. In other words, students have to illustrate a mathematical, semantic relation by means of a verbal text, with the option of adding symbolic expressions and other signs. Basically students had at least three kinds of data: (1) those available from the definition of  $f$ ; (2) those available from the four graphs; (3) the ‘closure’ condition “Among the following graphs one corresponds to  $f$ ”. The sentences that are logical consequence of the definition of  $f$  (in the context of classical mathematics) are of course a countable infinity. Of course we expect that students will focus on a small choice of them, such as, for example,  $f(0) = -2/3$  or  $f(0) < 0$  or  $f'(0) = 2/9$ . As regards graphs, the sentences obtainable are infinite too. The process is a bit more complex as the interpretation of graphs anyway requires some conventions. Properties like domain, continuity, differentiability and passage through given points cannot be inferred from the graph alone. At any rate, it is crucial for science students mastering multiple representations. The competencies required to devise counterexamples showing that properties of the kind mentioned above cannot be inferred by the graphs are not included in mathematics curricula for science undergraduates. So there is no alternative to compromise, in relation to the teaching goals. In our classes we usually accept that students, when dealing with a graph, adopt naive interpretations of properties like domain, continuity and differentiability. We usually require a more critical attitude towards properties such as the behavior of the function out of the range represented and the choice of the units of the axes. All of these aspects can be explained by means of examples, problems and activities that are within the reach of our students. So we expect that from the graphs the following properties are inferred.

*Graph A:* the function associated ( $f_A$ ) is negative and decreasing in  $(-3, 0)$ ;  $-1 < f_A(0) < -0.5$

*Graph B:*  $f_B$  is negative in  $(-3, 2)$ ;  $-1 < f_B(0) < -0.5$

*Graph C:*  $f_C$  is negative in  $(-3, -1)$ , positive in  $(1, 3)$ , increasing in  $(-3, 3)$ ;  $f_C(0) > -0.5$

*Graph D:*  $f_D$  is negative in  $(-3, 3)$  and increasing in  $(-3, 3)$ ;  $-1 < f_D(0) < -0.5$

The closure condition (see above) is perhaps the most important piece of information, as it makes reasoning by exclusion possible. Without this piece of information the problem would not be solvable. As a matter of fact, in many cases (even though not in all) it is possible to decide that a given graph does not correspond to a given formula, but it is never possible to be sure that a graph corresponds to a given formula. A Cartesian graph, for example, represents a function only in a limited range and in an approximate way. For any graph given in a real interval, there are infinite functions that might be associated to it. In a wide range of school problems, and in particular in many of real world ones, data are almost never usable at once, but they need anyway to be identified and extracted and afterwards they require some basic competencies in order to be used. Also, a seemingly primitive property like  $f(0) = -2/3$  requires to operate a replacement and apply some arithmetic operations, which implicitly involve a number of properties (and competencies). Even the recognition that the function  $f_D$  is negative in the range displayed requires some acquaintance with the conventions usually adopted to draw graphs, and some linguistic competence to master the meaning of words like ‘negative’ without

confusing it with ‘decreasing’ or with other words. In the same way, recognizing  $f_D$  as ‘increasing’ requires some knowledge of the appropriate definition.

## Criteria

In order to analyze teachers’ comments, we have taken into account the following aspects.

1. The aspect of the argumentation they have focused on (e.g., mathematical, linguistic or logical correctness, communicative adequacy, explicitation level of logical relationships).
2. The overall evaluation of each argumentation, with special care to contrasting evaluations.
3. Any other specific remarks about mathematical, linguistic and argumentative aspects.

## Outcomes

Of the 9 mathematics teachers only one (Flavia) considered the texts from the viewpoint of argumentation, while 7 of them almost exclusively focused on mathematical content. One of them focused on both mathematical content and language. Also Maria, the Science teacher, and Alberto, one of the Philosophy teachers, considered aspects related to argumentation. In particular Maria took into account the *explicitation* of the links among the parts of the texts produced by the students. Sara, the other Philosophy teacher appeared more interested in language. As far as mathematical content is concerned, the two Philosophy teachers did not make any remarks.

The teachers provided different and even contradictory evaluations of the argumentations, especially as far as Student 2 is concerned. Ada, Franca, Oriana and Sara place it among the best, whereas Aldo, Carlo, Fabia, Giulio, Lisa and Maria place it among the worst ones. Claudia and Giorgio considered the five texts substantially equivalent. The first group of teachers appreciated the conciseness of the argumentation of student 2. On the contrary, some of the other teachers found the argumentation incomplete. Giulio commented on this text in a different way compared to the other teachers. He claimed that “it is impossible to find  $-2/3$  on the graph, unless the unit is given divided into three parts, which is not the case, since on the y-axis there are multiples of 0,5 only”. He also claimed that, even this would be possible, “it would not be enough to exclude graphs A and B”.<sup>2</sup> From the interview, we gathered that Giulio thought that student 2 had stated two relevant facts but had failed to relate them with the goal of the argument. The text of student 3 has been criticized by some teachers as “redundant”. As a matter of fact, the student has explicitly excluded three cases to select the fourth. The structure of his argument is logically much more acceptable than explanation 2, which is compatible with wrong interpretations of logical consequence.

The most common objection raised by some mathematics teachers concerns the association of the sign of the derivative at a point to the monotonicity of the function at that point, whereas speaking of intervals would have been more correct. For example, Lisa, commenting on explanation 4, writes: “Once more we find confusion between pointwise derivative and monotonicity of the function in an interval”. Nonetheless, the same teacher, when summing up, states: “The reference to pointwise derivative, which is common to all explanations, could be accepted if one assumes that the students mean to refer to a neighborhood of the point”.<sup>3</sup>

<sup>2</sup> From  $f(0) = -2/3$  one can exclude graph C only. To exclude graphs A and B more information is needed, such as  $f'(0)$ .

<sup>3</sup> This difference is not relevant to this problem as all of the functions involved are continuously differentiable.

Some of the criticism involves aspects related to style, such as the use of plural forms (“We exclude ...”, “... we consider ...”) or of expressions like “letter  $D$ ” in place of “graph  $D$ ”. For example Ada comments: “In the conclusion expressions like ‘the graph of the function is letter  $D$ ’ do not sound well”. Some other remarks involve the (linguistic) confusion between “graph” and “function” or between a point and its  $y$ -coordinate, labelled as “imprecisions”. On the other hand, Aldo, Fabia and Maria spot problems that severely affect the understandability of the text, such as the lack of subjects or of connectives. Fabia speaks of explanations “linguistically inadequate for undergraduates”. Student 3 has been criticized for the use of “probably”, even though with different motivations. Giorgio thinks it is a mathematical error, for in classical mathematics a sentence is either true or false. Oriana claims that “it cannot be accepted in any case”. On the other hand, Ada, Fabia and Lisa interpret it as lack of confidence. For example, Lisa writes “the student is not fully convinced that the others can be excluded”.

The specific issue of argumentation has not been dealt with much. Aldo is the only one who explicitly analyzes the structure of arguments, in a classical way, in terms of premises-conclusions, possibly related to the model of Aristotle’s syllogisms. In his opinion “In no argumentation are premises and conclusion properly identified”, although he regards the arguments overall acceptable. Fabia, Giorgio and Maria underline the topic of the explicitation of the links among statements and remark that the argument of student 3 is the most explicit of the lot.

## Final remarks

Most of the mathematics teachers involved have focused on mathematical content. It seems that their view of mathematics is still oriented to knowledge rather than to competence or reasoning. In other words, their view seems sharply acquisitional rather than discursive. Moreover, some of the objections raised involve aspects (such as the questions related to pointwise differentiability) that are not crucial for students who need a basic mathematical education only. The same teachers seem not regard argumentation as a relevant part of mathematical instruction. This suggests to teacher educators that there is still much attention to pay to teachers’ interpretation of mathematics education and to familiarise them with the learning potential of argumentation. It suggests also that teacher formation should focus on argumentation as a component of mathematical competence, rather than as an additional subject to be taught. A nice discussion, at the educational level, of these topics, has been provided by Freudenthal (1988), who clearly related the logical topics in mathematics education to language. The interdisciplinary character of argumentation is damaged if it is narrowly interpreted according to the schemes of some content domain, such as mathematical logic, philosophy or law. Most of them seem to regard linguistic competence as conformity to some pattern rather than adequacy to some functions or goal. This is the case of teachers criticizing the use of plural forms or of expressions like ‘letter  $D$ ’. These may not correspond to some stylistic patterns but surely do not severely damage the readability of the text. Moreover, some teachers seem to give value to concise texts rather than to more extensive ones. It is possible that high school teachers’ expectations of undergraduates’ linguistic competence are too high and that they assume that undergraduates can fluently use literate registers, i.e. the more educated varieties of language. This unfortunately does not often happen. The use of plural forms and of ‘probably’, which has been criticized by some teachers, seem to be related to the interpersonal metafunction of language rather than to the ideational

one. In other words the students using such wordings did not mean to express some specific content but to position themselves in relation to the instructors or even to the other students. On the other hand, only three teachers notice some more substantial weaknesses of the texts, such as the lack of subjects or of connectives, which severely damages the accessibility of the text. In our experience of undergraduate teaching, this is a major problem with a number of students. This is not just matter of style, but, in a framework assuming that language plays a major role in the development of thought, it is a major obstacle for students, who lack the means for effectively representing and compacting information and verbally expressing the organization of their thinking process. It seems that some teachers do not recognize the importance of the language demands of a formal proof and do not relate them to the field of mathematical instruction. Verbally expressing argumentation can allow students to become aware of its logical structure, but the language means to do that, such as connectives and their combination within sentences, are crucial (Prediger & Hein, 2017). We have a feeling that some of the teachers involved had too high expectations about the mathematical competence of the students involved, as far as they were at university rather than at high school. In the future we need to improve the methodology to reduce the bias caused by the teachers' view of undergraduate studies, for example by asking them to evaluate argumentations produced by high school students of their or other schools. We propose also to expand the number of teachers involved (including both mathematics and other subject teachers) and to use these results in teacher education activities.

# The role of writing in the process of learning to speak mathematically

Marei Fetzer

Goethe University, Frankfurt, Germany; [fetzer@math.uni-frankfurt.de](mailto:fetzer@math.uni-frankfurt.de)

*A lot of research is being done on the interplay of mathematical learning and language skills. However, graphic aspects have been met with little response so far. What role does writing play in the process of improving language proficiency? This paper empirically reconstructs how language use develops within one lesson that provides manifold opportunities for students to negotiate and discuss. Special attention is paid to the role pupil's written notes play within that development.*

*Keywords: Language skills, writing processes, mathematical learning.*

## Introduction

We know that language plays an important role in mathematical learning. Consequently, mathematics education is not only about teaching and learning mathematical ideas and concepts, but also about the development of a language that reaches the demands of describing mathematical activities and expressing fundamental ideas. Mathematical and language learning accompany each other. One approach to improve mathematical and language skills in an interconnected way is to initiate interactive learning situations. Such discursive situations are meant to encourage language use *and* mathematical learning. Why should that work? First, language serves a communicative function. So it appears to be a platitude that learning language requires using language and interacting with others. Second, language fulfills a cognitive function. The challenge to develop mental mathematical objects is strongly linked to the availability of appropriate means of expression and language skills. Not only theories on language support the assumption that interactive learning situations are beneficial for cross-linked mathematical and language learning. However, the conceptualization of learning as a social process backs that idea. Learning takes place in the process of participating in interactive situations (Miller, 1986; Fetzer, 2007a). Referring to social frameworks of learning, all participating students should benefit from such a proceeding. Those who actively contribute to a mathematical discourse improve their language skills by developing an appropriate language that has the potential to convey their idea. Those who rather receptively attend the situation might profit by being part of a mathematical discourse. They might not only catch up mathematical ideas, but also ways to express them. But how does language use develop in classroom interaction? Graphic aspects seem to play an important role in settings that challenge mathematical language development; taking notes on solving processes, recording explanations and accounting for answers in a written way are constituent elements of cooperative classroom settings. Consequently, when studying processes of learning to *speak* mathematically, the role of *writing* should be taken into account. What role do graphic aspects play within that development? This paper provides a closer look at the two essential situations concerning these research questions: the phase of writing, and the phase of presenting on the basis of graphic notes.

## Development in language use

In order to describe developments in language use, we need to specify. Koch and Oesterreicher (1985; Oesterreicher, 1997) offer a distinction in two dimensions of language: the medial and the conceptual.

The medial dimension is dichotomic: language can be either specified as phonic, when something is said and can be heard, or, it is assigned to graphic forms like writing. In contrast, the conceptual dimension is gradual. Language can be conceptually rather oral or rather written. It stretches between the poles of communicative nearness (oral) and communicative distance (written). This specification applies for both, medially graphic and medially phonic, forms of language. Talking with a good friend for example is closer to the conceptually oral pole than a presentation at a conference. A newspaper article is ‘more’ written than a twitter post. If we talk to our child when having breakfast, we might use short and incomplete sentences and combine them with gestures. As we are in a face-to-face situation, we can react directly to our counterpart and spontaneously negotiate our roles. Koch and Oesterreicher call this a language of nearness. The strategies of communication belong to the pole of orality. In contrast, conceptually written language refers to the pole of literacy and language of distance. It is used when the interlocutors are not necessarily in direct relation and the processes of speech production and speech reception might be separated from each other. Thus, aspects of the situational and cultural context have to be made explicit. Consequently, sentences are more complex, main clauses and subordinate clauses are formulated. Specific terms come into play to be precise and explicit. Koch and Oesterreicher call this a language of distance. Examples are a text of law (graphic) or a scientific lecture (phonic).

Koch and Oesterreicher help to classify the registers of everyday language and academic language (Cummins, 2008). Halliday describes a register as “a variety of language, corresponding to a variety of situation” (1985, p. 29). According to him, the term register points to the detection that individuals adapt their use of language to a given situation. Thus, the register of everyday language is rather conceptually oral, no matter which medium is realized. It has to fulfil the function of a fast and unproblematic communication in our everyday life. As such, the oral language may be supported by gestures or by reference to a context. Words do not have to be clearly defined and sentences may be short or even incomplete. In contrast, the register of academic language is conceptually written, again irrespective of its medium. In academic contexts, language should be as explicit and precise as possible and intelligible without any reference to a specific situation. For that reason, words have to be well defined. Sentences might be complex in order to reflect relations.

Eventually, there is the register of mathematical language. It is an academic register related to a certain field; mathematics. Technical terms like probability, multiplication or subtracting, as well as specific sentence structures, are constituent elements of mathematical language. Especially on the medially graphic level, very short and decontextualized sentences or graphic representations are characteristic for that register.

In mathematics classes, we face the challenge to develop individual language use from orality towards literacy, from everyday language in the direction of learning to speak and write mathematically. The learning and teaching situation remains the same: students and teacher know each other and interact face-to-face. Nevertheless, a development towards precise and decontextualized academic, respectively mathematic, language has to be initiated. Fetzer (2007a; b) proves empirically that writing in mathematical classes and mathematical discourse on the basis of students’ written works fundamentally support *mathematical* learning. In this paper, special focus is put on *language*

development, and the way in which the implementation of medially graphic elements helps to provoke a move in the direction of literacy is reconstructed.

## Data and methodological aspects

The examples analyzed in this paper are taken from the empirical study MitMaL (**M**iteinander **M**athe **L**ernen) (Co-operative Mathematical Learning). In this study, cooperative and individual learning settings are compared to each other. Two math classes were observed and video- recorded for a couple of weeks. Both groups dealt with the same mathematical subject, but implemented different methodical approaches. In one class (group i), individual learning situations dominated. In contrast, the other teacher predominantly initiated cooperative group work and provided the opportunity for mathematical whole class discussion (group c). Pre-test, post-test and follow-up-test constitute the quantitative part of the study. Analyses on the transcripts of the videos account for the qualitative part of the study. They are conducted in a reconstructive manner applying analyses of interaction (Cobb & Bauersfeld, 1995). This method refers to the interactional theory of learning and is based on the ethnomethodological conversation analysis. In contrast to conversation analysis, it focuses on the thematic development of a given face-to-face interaction rather than on its structural development.

The videos for this paper are taken from group c, who worked in a cooperative manner. In order to reconstruct the development of language use, the paper concentrates on one single math lesson on probability in grade four. Debora is accompanied throughout the whole lesson. In this way, her individual performance and development can be reconstructed from the beginning until the end of the lesson. Special attention is paid to the role the notes taken in the group work play in the presentation. How do they influence the verbal language skills?

## Empirical example

The empirical example is taken from a math lesson on probability. 24 students of grade four try to find out which of the four given rules is the best to win when turning a colored wheel of fortune. The wheel of fortune is equally divided into eight sections, numbered 1 to 8. Two fields are red, two are blue, three are green, and one is white. The rules are: (1) *You win with 1, 2 or 3*; (2) *You win with red*; (3) *You win with white or blue*; (4) *You win with 2, 4, 6 or 8*. Card four is the most probable to win.

The lesson starts with a thematic introduction in a whole-class situation. The tutor presents the wheel of fortune, and some students go for a first attempt. Afterwards, the children work in groups of four. They are equipped with a wheel of fortune, one set of cards with rules, and with a task sheet: *Work together and find out which rule is likely to be the best to win. Why do you think so?* The challenge is to work on the tasks, take notes and give reasons in written form. At the end of the lesson, children and tutor come together. They discuss their findings with their written notes at hand.

**Language use in the context of probability:** Talking about probability requires mathematical terms like probable, improbable and equiprobable. In German, ‘probable’ sounds familiar to children. The expression is used in everyday language and is applied in the sense of ‘perhaps’ or ‘might be’. In contrast, ‘improbable’ and ‘equiprobable’ sound rather strange to young students. These expressions belong to the academic, respectively mathematical, register. However, talking and writing mathematically requires more than academic expressions and mathematical terms. Describing,

explaining and giving reasons require academic language proficiency on the sentence level. In this particular task, the students first have to describe their selection in written form. This is possible using a main clause. Conceptually spoken language in everyday register meets the demands. In addition, an explanatory statement on their selection is required. This is much more challenging, as German language demands subordinate clauses in order to formulate causal connections. In contrast to main clauses that are structured subject – predicate – object, subordinate clauses are put together in an inverted structure: subject – object – predicate. This inversion does not necessarily belong to the everyday register. The outstanding challenge in the context of probability is the fact that we do not only need a causal conjunction followed by a subordinate clause with inverted sentence structure, but also an infinitive clause as a third component. This last aspect clearly belongs to academic language. To put it in other words: in order to compliment the decision with reasons and justification, not only mathematical terms, but academic registers and complex sentence structures are especially necessary.

**Material for the group work:** The rules rely on conceptually spoken language. They address the students directly and refer to the concrete given context of turning the wheel here and now. Mathematically spoken, it rather aims at a situational or context-bound understanding of probability and representativeness of personal attempts rather than at abstraction. The rules provide for a strong link to the students' experience on the one hand, and to their everyday language on the other hand.

The tasks (see above) apply conceptually rather spoken language as well. Again, the students are addressed directly. None of the mathematical terms of probability is used. Instead, the children are asked to choose one of the cards. A second sentence aims at an explanation. Interestingly enough, these colloquial questions can hardly be answered on a conceptually spoken level: if you work on the task in the order of appearance, you first have to determine the selection. That is easy. Afterwards, you need a causal subordinate clause and the infinitive clause, which is grammatically complex. In principle, conditional connections could be a solution: "If you choose..., you are likely to win. That is because..." This structure is much easier in German than the causal connection. Nevertheless, it clearly belongs to the academic register. However, such an answer is only possible if the students have already reached a rather high level of abstraction at this time. Condensed: if students work on the tasks and provide answers, they either have to fulfil a move on the conceptual level from spoken to written language, or they have to develop an abstract understanding that enables them to choose a slightly less complex language use.

**Beginning of the lesson (phonic):** Children and tutor are sitting in a circle around a colored wheel of fortune ready to be spun. Debora does not contribute to this opening. The tutor starts the lesson referring to the students' experiences with wheels of fortune: "Perhaps you know something like this. Such a wheel of fortune has something to do with winning or not. This is why it's called wheel of fortune, cause if you win, you are lucky". (Wheel of fortune is '*Glücksrad*' in German, and being lucky is '*Glückhaben*'). In the first introduction to the theme, the tutor links not only the context of own experiences with the mathematical context of probability, but also different language registers. She plays on the fact that *Glück* bridges both registers. Pointing at the paper wheel of fortune, she moves her finger around in circles and says: "Today we have a closer look at the wheel of fortune." Repeatedly in this introduction, she moves her finger in this manner as if she spun the wheel. By doing this, she might strengthen an activity-orientated representative understanding of probability:

Rule X wins because my own (little) random sample ‘proves’ it. This understanding does not claim for decontextualized academic language.

The tutor’s language changes within the introduction. First, she seems to pick the students up and see them through by applying the everyday register. She distinguishes “good rules” you are likely to win with, rules you might “not necessarily” win with and rules that make it “quite impossible” to win. When explaining the task, she even grades further down and speaks of “a good way to win” and “stupid cards”. This colloquial language is accompanied by the turning gesture. Acting and speaking like this, the tutor marks the concrete situation as the starting point of the experiment on probability. Not before her last sentences, she uses the mathematical expressions: “For example, with this card, you will most probably win; with these two cards, it is perhaps equiprobable to win; and with this one, it is rather improbable.” This is the only time these terms are quoted in the introduction scene.

**Group work (phonic and graphic):** For a closer look at the group work, Debora’s group is chosen exemplarily. Three phases of language use can be reconstructed within the working process: (1) conceptually spoken language, (2) everyday language with scattered mathematical terms, (3) everyday language with specifications and conjunctions.

(1): Debora is the girl to take the initiative in the group. She suggests cutting the wheel out. While doing this, she lays the foundations for an activity-orientated approach and context-specific experiences. This first phase is dominated by the register of everyday and conceptually spoken language. Sentences remain incomplete; gestures play an important role for understanding. The challenge of writing is no issue of negotiating yet. The following scene emerges as soon as the girls have read out the rules. It illustrates the register of everyday language the girls apply.

Debora:	<i>Points at Dalya</i> That’s best
Sara:	Yes
Debora:	<i>to Dalya</i> say it again <i>reaches for the wheel and takes it</i>
Dalya:	I got <i>reads out her card</i> you win with 2/ 4/ 6/ or 8\
Debora:	<i>puts her fingers on the wheel</i> it’s the majority- all fields but three-
Sara:	<i>points at one field</i>
Debora:	I see- <i>moves her fingers on the wheel</i> five as well/
Sara:	no
Debora:	<i>looking at the wheel, fingers still fixed on fields</i> makes no difference- it’s equal\

However, they work straightforward on the task and find a first solution that is mathematically correct. The choice is formulated using conceptually spoken, deictic and context-bound language: “That’s best.” No mathematical term is applied. A first approach to explanation might be the physical detection (by touching) of four (out of eight) ‘lucky’ fields.

(2): The second phase can be characterized by conceptually spoken language with scattered mathematical terms. Graphic aspects still do not come into play. In this scene, one can reconstruct one example of how mathematical language works its way into the discourse: Debora picks up a comment from a neighbouring group “Red is the most improbable.” She spontaneously integrates the

term in her active language use and confirms with a look on the wheel: “Yes, red is the most improbable.” In the following, this term remains a constituent part of the interactive process. All four girls stick to conceptually spoken language using the register of everyday language. Their sentences remain incomplete with scattered mathematical expressions. For example, Debora sums their findings up as follows: “Red is the most improbable. One, two or three is same, and Dalya’s is best.”

(3): As soon as it comes to *writing*, there is no way of supporting words by pointing or showing. Written language has to carry the whole meaning. Accordingly, writing mathematically arises the necessity to develop language use. Debora’s group works sequentially. First, they answer the first part of the task: *Work together and find out which rule is likely to be the best to win*. They choose the conceptually spoken wording of their verbal formulation from the beginning “That’s best” and elaborate on it: “Best is card four which says you win with 2, 4, 6 or 8.” The deictic component of the face-to-face interaction is replaced by naming the card “card four”. The necessity to write results in specifying the concrete situation. The rule is taken from the card and copied word by word. This appears to be an appropriate strategy to create an answer that is socially accepted as ‘good mathematical language’. At the same time, the sentence structure remains conceptually oral. The elements ‘specification by concreteness’ and ‘copying phrases’ are put together one after the other. Though the subordinate clause is introduced with the appropriate conjunction, it is not conducted in the right grammatical arrangement.

Later in the group work, the tutor reminds them to provide reasons for their decision. Subsequently, Dalya picks up the pencil.

Julia: Because they are well spread\

Dalya: *holding the pen* Yes-

Julia: *points her finger to the paper* Well- because they are well spread on the turntable\

Dalya: *yes writes*

Julia: Wheel of fortune – write wheel of fortune\

Dalya: Well- we’ve found a because- uhm I’ve written *reads out* best is card four which says you win with 2 4 6 or 8 because they are well spread on the wheel of fortune.

Debora: spread *thumb up*

In this short scene, the justification is graphically recorded. The aspect of the winning fields being evenly or well spread on the wheel of fortune was mentioned earlier only once by Julia. At that time, her idea would not come through in the interactional process. Why is she successful now? The tutor directly addresses the group and asks them to find a justification. The girls are running out of time. In this situation, Julia starts her suggestion with “because”. Her first utterance is rather vague. Perhaps feeling supported by Dalya’s “yes”, she then elaborates “the turntable”. As a third move towards improved language, she implements a mathematical term “wheel of fortune.” Summing up, her suggestion is put forward at the right time within the solving process. Julia is working with the elements of *specification* and *integrating mathematical terms*. The *conjunction* ‘because’ indicates a justification. That was the task. The sentence structure itself still reminds of spoken language. This form of speaking mathematically appears to be convincing to the group members. Debora seems to

try that wording on her own by repeating it. Her thumb up can be understood as acceptance. Again, she picks up an expression and integrates it spontaneously in her active vocabulary.

**End of the lesson (phonic and graphic):** Gathering for the end of the lesson, the students have their sheets with their written works at hand. Debora is the first child to contribute in the presentation. As she hesitates and starts over twice, it seems as if she has to orientate herself first. In this situation, her group's notes appear to be helpful. After a quick glance at the paper, she performs much more fluently: "*Best* we found out is card four." In German, this is an example of conceptually spoken language: her word order is irritating. Precisely, 'best' is used as an adverb referring to 'to find out'. Taking into account the given context, it appears to be more reasonable that she uses 'best' to characterize card four. Thus, her sentence structure is grammatically incorrect. Instead, it might reveal her order of remembering: we had to select ("best"), we had to work ("we found out"), we made a decision ("card four"). Here, the notes appear to support the memory: what did we do? In the following, her language develops. "Cause best is card four". This is, in fact, only half a sentence. But, in contrast to the first attempt, it is in the right German word order. Then, she reads from the notes, probably in order to make sure to get the correct wording: "which says you win with 2 4 6 or 8". Turning her eyes away from the notes and looking to the tutor, she proceeds: "Cause they are quite well spread on the wheel of fortune." On the notes, the subordinate clause is in the wrong word order. Speaking aloud, she corrects the sentence structure. This can be interpreted as a step towards abstraction and language of distance. Her language develops towards academic register. Summing up, the notes warrant three aspects: orientation, reminder and thematic reassurance that helps to develop language skills.

Analysing the other contributions in this presentation confirms these findings. Every single contribution is thematically on point. Obviously, graphic notes help to *orientate*. Moreover, the students supply their comments with phrases that structure the whole presentation process: "We found out the same" or "Not as the others". That provides for orientation and structure not only within individual understanding processes, but also within the interactional discourse. The aspect of *reminding* of the own working process appears to take affect strongly. Every single student who contributes to the whole class presentation thematically closely links his or her comment to the notes. The quick glance at the paper is to be reconstructed in each sequence. Especially the observation that medially verbal language use improves compared to the graphic version in the notes confirms as an empirical result. For example, in one group, the notes say: "Weil Gewinnkarte vier das halbe Glücksrad einnimmt." (Cause winning card four takes half the wheel of fortune.). Contributing in the class, the presenting boy turns 'half' into a noun and combines it with a genitive construction ("nimmt die Hälfte des Rades ein"). Using substantives and genitive constructions is a German speciality, which is especially characteristic for academic register. Accordingly, this is understood as *development in language skills*.

## Conclusions

How does language use develop in cooperative classroom settings? What role do graphic aspects play? This paper provides a closer look at the two essential situations concerning these research questions: the phase of wiring, and the phase of presenting on the basis of graphic notes.

The necessity to *write* mathematically activates a development in language move at the conceptual level. Mathematical terms are embedded in rather spoken sentence structures; a first move towards mathematical language. Specification on the concrete context serves for more precision in descriptions. Even at the level of sentence structure, first developments can be reconstructed. On the one hand, students implement phrases that were socially accepted earlier as mathematically elaborated. On the other hand, they implement conjunctions. If-clauses and causal-clauses are characteristic elements of academic and especially mathematical register.

Presenting is eventually a medially verbal action. But, in the given case, graphic aspects work their way into interaction. They contribute fundamentally to orientation, structuring and reminding both individual learning processes, and the interactional process. Particularly the graphic notes thematically reassure students and thus provide capacity to develop language skills.

## Solving problems collaboratively in multi-age classes – a possibility for learning?

*From an interactionist perspective, interaction is seen as a foundational constituent of mathematical learning, as it creates the possibility for students to negotiate meaning, which then can lead to the construction and/or modulation of meanings which outlast the situation - framings. According to Krummheuer (1992), this is seen as learning. In multi-age classes, students have even more diverse framings than in single-age classes and when they are given the opportunity to learn collaboratively, an increased need to coordinate their framings might lead to an optimised possibility for learning. This research project has the objective of identifying how students participate in processes of collective negotiation of meaning and therefore how possibilities for learning mathematics emerge. First analyses show that the possibilities for learning emerging in the interaction vary depending on whether differences in framings can be coordinated and a taken-as-shared meaning is brought forth.*

*Keywords: Multi-age education, collaborative learning, interactional analysis.*

### Multi-age education

No matter the school, students in a classroom are never homogeneous, also in relation to their learning preconditions. Each individual is unique and therefore has differing abilities and experiences. Using age as the distinguishing factor for placing students in specific classes is the norm, because it is seen as a possibility to make classes as homogeneous as possible. But even in learning groups which are homogeneous in age, the differences in students' preconditions for learning can be up to five years at the time they enter into school (Lorenz, 2000, p. 22). One concept with the aim to purposefully value and meet this existing diversity is merging students of different ages and grades in one class deliberately (Prengel, 2007, p. 69), which can be referred to as *multi-age classes*. The benefit in making learning groups heterogeneous in age is e.g. seen in that, because the diversity of learning preconditions increases, the necessity for differentiation increases also. However, mathematics is often presumed to be a subject built up rectilinear whose content can only be learned following a specific order (Lorenz, 2000, p. 19). Nührenbörger and Pust (2006) found that because of this common assumption students in multi-aged classes are rarely given the opportunity to learn from and with others in mathematics classrooms. Instead, this often causes extremely individualised and separated learning to take place as teachers either feel they need to separate the learners back into the different age groups or they need to let each student learn individually at their own pace in order to meet the increased diversity of the students. However, both of these waste the opportunity seen in collaborative learning (Nührenbörger & Pust, 2006, p. 17), especially from an interactionist perspective on mathematics learning.

Besides overarching concepts, which have been developed for collaborative learning within multi-age mathematics teaching (e.g., Nührenbörger & Pust, 2006), interactions between learners who are

heterogeneous in age have been examined within multi-age mathematics education research. These studies predominantly focus on dialogues between two students from different grade levels and concentrate either on how knowledge is constructed in the interaction (Nührenbörger & Steinbring, 2007) or on when interactions are beneficial for learning in these settings (Gysin, 2018). Our focus is also on possible benefits for students' learning conditions when children with diverse preconditions interact with each other while solving problems collaboratively. However, we base our study on the interaction theory of learning, which will be described below, and include analyses of group settings of three students working together.

## **Interaction theory of (mathematical) learning**

From an interactionist perspective, the individual process of learning is constituted in the social process of the negotiation of meaning. The social interaction, therefore, holds the potential to generate meanings new to the individual. Especially for young learners, interaction is seen as a foundational constituent of learning. In this context, Miller (1986) creates a sociological theory of learning of at least two individuals – the theory of collective learning processes – in contrast to psychological theories of learning which predominantly focus on isolated individuals. Hereby, he does not, on principle, question that learning is also an individual process, but rather that, when learning fundamentally in the early stages of a child's development, an interactive collective process precedes or determines this process of learning something new (Jung & Schütte, 2018). In this sociological theory of learning, the concept of argumentation is essential and Miller (1986, p. 37) differentiates it from “communicative action.” Argumentation, and hereinafter more specifically collective argumentation, is mainly characterized by the aspect of rationality, whereas communicative action is based on something uncontroversial. Mathematical learning, therefore, takes place when two or more people negotiate what is viewed from a mathematical perspective as rational. Krummheuer and Brandt (2001) draw on this aspect of learning in collective argumentation and create an interaction theory of mathematical learning. For them, it is of great importance that students participate in collective argumentation within classroom interaction in which meaning is collectively negotiated (Krummheuer & Brandt, 2001, p. 20). This, at best, will lead to learning to occur which is seen as the construction and/or modulation of meanings which outlast the situation – also called framings (see below) (Krummheuer, 1992; Jung & Schütte, 2018, p. 1091) and can be reconstructed in the increasingly autonomous participation in these collective argumentations (Krummheuer & Brandt, 2001). Based on this understanding of learning and the significance of interaction in mathematics learning, diverse theories with rich empirical content have been developed in recent years from a foundation of “sensitizing concepts” (Blumer, 1954, p. 7) – a kind of theoretical skeleton for the interaction theory of learning, which will be described below.

At the beginning of an interaction, the participants develop preliminary interpretations of the situation on the basis of their individual experiences and knowledge – called *definitions of the situation* (Krummheuer, 1992). Furthermore, participants in the interaction attempt to attune their definitions of the situation to each other, ideally leading to the production of *taken-as-shared meaning* (Voigt, 1995, p. 172), a working consensus. The participants' interpretations of a situation can never be exactly the same, however, by creating an understanding between them concerning the objects, ideas and rules of the interaction, the participants are enabled to work together. The result of the

participants' negotiation only is something “temporarily” which serves as a basis for further processes of negotiation but might also be rejected or transformed as the interaction unfolds (Bauersfeld, Krummheuer, & Voigt, 1988; Voigt, 1995). The taken-as-shared meaning – *the working consensus* (Goffmann, 1959, p. 9) – is on the one hand socially constituted and, on the other, potentially novel for the individual if it pushes systematically beyond his or her interpretive capacities. The working consensus represents the ‘stimulation potential’ of individual cognitive restructuring processes. When taken-as-shared meanings are brought forth repeatedly in the interaction, the participants' individual definitions of situations can become standardized and routinized and can therefore be produced by the individual in similar situations. Drawing on Goffmann (1974), Bauersfeld et al. (1988) call these definitions *framings*. Thus, ideally, mathematical ascriptions of meaning which sustain beyond the situation (framings) are constructed, or the working consensuses, which are repeatedly collectively negotiated, ‘converge’ in individual mathematical framings.

However, it often happens that the framings produced by young learners either among themselves or in interaction with individuals with advanced skills are not in alignment with each other (Krummheuer, 1992). Students, for example, each interpret situations based on framings from the environments they have experienced outside of school and in their previous school career. In order to maintain the progressive mutual negotiation of content relating to a particular theme, the *differences in framing* between the participants need to be coordinated. This coordination should be done by an individual who is advanced in the subject-specific interaction. While these differences in framing can make it more difficult for the participating individuals to adjust their definitions of the situations to fit each other, they also provide the “‘motor’ of learning” (Schütte, 2014, p. 927) since, on the interactional level, they generate a certain necessity for negotiation.

### **Analysing students' participation in processes of negotiation of meaning**

One of the unique characteristics of multi-age education is that learners most likely have even more diverse framings than in single-age classes. We believe that this can provide an optimized opportunity for learners when working collaboratively, as there is an increased need to coordinate their differences in framing by negotiating meaning. In order to coordinate the differences in framings, the students have to bring forth a working consensus collectively. This can then lead to the construction and/or modulation of framings which is seen as learning. Based on this interaction theory of learning, the overall question this research seeks to address is: How do students participate in processes of collective negotiation of meaning within multi-age mathematics education and do possibilities for learning mathematics emerge.

### **Interactionist approaches of classroom research**

Methodologically, this work can be located within qualitative methods of social research which follow a reconstructive-interpretative qualitative approach and have the aim to ‘understand’ the actions of the individuals participating in class and develop local theories (Schütte, 2011, p. 776). More specifically, this work is located within interactionist approaches of mathematics educational classroom research (e.g., Krummheuer, 2011). For this study, the classes are filmed several times over a period of one to two years in order to reconstruct possible age-specific changes concerning the participation in collective argumentation of the children. The interactions of the students are then

transcribed and analysed using the interactional analysis, which was first deployed in the area of interpretive classroom research in mathematics education in studies by Bauersfeld et al. (1988). The interactional analysis allows to reconstruct the ways in which negotiations of mathematical meaning are interactively constituted by individuals. Furthermore, it can help to reconstruct patterns and structures of verbal actions of the teacher and the students. Overall, this research seeks to describe how mathematical learning takes place collaboratively in multi-age education and will use the sensitizing concepts in order to describe these processes.

## Collective argumentation of students in multi-age education

The group works analysed in this paper are from a mathematics lesson in a multi-age class including 24 children from first, second and third grade. At the beginning of the lesson, the students are divided into groups of three which mostly contain one student of every grade level. The students are given this task: “Tina and her family want to decorate their Christmas tree with hand painted Christmas ball ornaments<sup>1</sup>. They want every ornament to look different. To paint the ornaments, they have the colours red, green and blue. With these colours, they can paint dots or stripes. For each ornament they want to use two colours and one pattern at the most. Which possibilities do they have when painting their ornaments?” To solve this task, the students have material on their tables which includes circles, stripes and dots of each colour to try out different combinations without painting them. The interactions of two groups of three students, including a student from every grade level, working on this task were analysed and the summaries of these analyses will be presented below. Afterwards, the analyses will be compared to each other and a conclusion will be drawn.

### Analysis of the first group work

The first group includes Isabella (1<sup>st</sup> grade), Hans (2<sup>nd</sup> grade) and Elias (3<sup>rd</sup> grade). During the first part of this group work, the students start by creating two green circles, one with red stripes and one with blue dots. Then the following interaction emerges.

#### Transcript 1: Excerpt of the first group work

1		Isabella	I wouldn't just use green now but (if we) also the other two colors [ <i>points to the blue and red circle</i> ]
2		Elias	on red wait [ <i>takes a big red circle from the pile</i> ] on red we could [ <i>picks up a small blue dot</i> ]
3		Hans	no now now [ <i>touches red dots</i> ] now green dots [ <i>picks up two small green dots</i> ]
4		Elias	no we already have green dots . twice [ <i>first points to a big green circle and then with two fingers to the two green circles with patterns on them</i> ]
5	<	Elias	now we have to
6	<	Hans	but green dots [ <i>places his two green dots on the red circle in front of Elias</i> ]
7		Elias	yes okay . that that yes

In this excerpt, Isabella argues that they should not only use green circles but also the two other colours because they should not only use the same colour <1>. Elias then picks up this idea and starts

---

<sup>1</sup> In Germany, Christmas trees are often decorated with different kinds of ornaments (e.g. ball ornaments) which can be in one or more colors. Therefore, children in Germany are usually familiar with ball ornaments.

suggesting to put blue dots on a red circle <2>. Hans also follows up on Isabella's idea and suggests to put green dots on a red circle <3>. Elias seems to misunderstand Hans' utterance and reiterates Isabella's idea <4>. Then Hans repeats his idea to clarify it <6> and Hans and Elias agree on creating a red circle with green dots <7>. Hans and Elias then briefly disagree on the number of dots they should use but both seem to implicitly agree that for the differentiation of the possibilities the number of dots is not relevant. After settling for three, they also disagree on which background colour they should continue with. Elias now suggests to use a blue circle but Hans disagrees and suggests to create a second red one using the other colour left for the pattern (blue). They then agree on using a red circle and add two blue stripes. Isabella says that she has found another possibility and points to a blue circle with one green stripe. Contrary to Elias who then says he wants to create another red circle with a pattern, Hans explains that they have created two green and two red ones so far and suggests to now create blue circles. All three quickly agree that they will first use a blue circle with red dots.

In this part and in the continuation of this group work, one can see that all three children participate in the creation of the possibilities. All of them contribute suggestions but also disagree with each other directly. However, before they continue working on the next possibility, they always come to an agreement concerning a possibility. In doing so, they collectively negotiate their suggestions. In the arguments, which are brought forth in the processes of reaching agreements on the procedure and correctness of the specific possibilities, various strategies of the children can be reconstructed (even usage of all colours; maximum difference in the materials used; alternating colours and patterns at the same time; aesthetic reasons such as using the same or deliberately different number of dots and stripes; conservative usage of materials to avoid wasting materials). The two strategies which prevail – even usage of all colours, as well as the variation of the number of dots and stripes for aesthetic reasons – are both introduced by Isabella first and then picked up by Elias and Hans. It is noticeable that Isabella contributes a lot of ideas but does not implement them directly but rather formulates them in the subjunctive. Because she mainly relies on verbal suggestions without using the material, whereas Hans and Elias often directly use the material while bringing forth a suggestion (e.g. <3, 4>), her suggestions and arguments are often very explicit. Elias, in particular, takes up Isabella's suggestions over and over again and implements these as well as his own suggestions. Hans primarily takes up Elias' suggestions but often also contradicts them and starts acting directly on his own. However, in these contradictions - at the beginning especially between Elias and Hans – no competition develops for who prevails, instead the contradictions are used for finding the best possible strategies and methods for solving the given task. Elias, in particular, involves everyone in the process of solving the task by asking for their approval. Therefore, a working consensus seems to establish that all three participants should agree on a suggestion (or at least no longer disagree on a suggestion) before moving to the next possibility. This leads to the group bringing forth collective argumentations in order to solve the emerging differences in framing. Throughout this entire task, they all continue to work collaboratively because, even though they briefly start working alongside each other once in a while, they always agree collectively on a possibility before moving forward.

In this group work, the differences in framings seem to be coordinated as the children bring forth a working consensus through collective argumentations. Therefore the possibility for learning can be reconstructed as this working consensus can lead to the students constructing new or modulating

existing framings. In further analyses, different roles of the individual students within these negotiations could be reconstructed more specifically. Elias, for example, seems to act as one who coordinates the differences in framings and therefore seems to help them come to a working consensus as a group.

### **Analysis of the second group work**

The second group includes Kim (1<sup>st</sup> grade), Erich (2<sup>nd</sup> grade) and Hannes (3<sup>rd</sup> grade). In this group, we can also see that all three children participate in the creation of the possibilities by making suggestions, responding to the suggestions of others, but also by acting immediately on their own suggestions. As a group, however, they only agree on a possibility briefly before revising it again. At the beginning, they start by working on one possibility collectively, however Erich's proposal is rejected by Kim and Hannes without giving clear reasons. Kim only says „no I believe I don't know if that will work with red dots I don't believe [*takes the red dots off the blue circle*]“ <78> and after Erich moves the blue circle Hannes says „no Erich red needs to go [*takes the blue circle which Erich moved and puts it in front of himself*] <82>. From then on Erich withdraws from working collaboratively. The disagreements between the children are often solved by exercising authority and rarely by giving arguments and if an argument is given, this is not taken up by the others. This is also reflected in the fact that from the start Hannes repeatedly contradicts suggestions by referring to the task – only two colours may be used – but then does not comply with it himself. Therefore, a pattern is established in which all three children work side by side. Kim and Hannes seem to interpret this situation as aimlessly trying out various possibilities, as Kim, for example, repeatedly rejects or reverses possibilities and never leaves a possibility permanently. Erich, on the other hand, seems to be looking for possibilities in a more structured way. His structured approach can also be reconstructed by him letting his suggestions remain visible and not taking them apart again like the other two. At different times during the group work, Kim looks at other tables and then introduces new suggestions for strategies for solving the task (using the sheet of paper; gluing the patterns onto the circles; using a more structured approach) but her suggestions are not taken up or even rejected by Hannes and Erich. All in all, it can be seen that all three act very autonomously right from the start but do not find a working consensus about how to solve the task. They then start working side by side, presenting their own suggestions to each other but when contradictions arise they neither bring forth arguments (other than aesthetics), nor agree on possibilities and secure their results as a group.

In this second group work, the few attempts of the participating children to coordinate the differences in framing, which emerge, fail and therefore no working consensus seems to emerge. This may be due to the fact that they bring forth separate arguments but no collective argumentation is brought forth. From an interactionist perspective, the possibility for learning in this group work is therefore limited as without bringing forth a taken-as-shared meaning the possibility for constructing new or modifying existing framings is impeded.

### **Conclusion**

When comparing the interactions of the two groups, even though all children participate in solving the task, from an interactionist perspective, only in the first group an optimized possibility for learning can be reconstructed. Therefore, solving problems collaboratively in multi-age classes can vary in the

way it enables possibilities for learning to emerge. In further analyses, collective argumentations seems to be initiated e.g. when learners explicitly verbalize disagreements or ask questions about the correctness of a solution as this seems to put the other learner(s) – often the more advanced ones – into an interactive obligation to bring forth arguments. In the process of the students then bringing forth the argumentation collectively, both the advanced and the less advanced student seem to have the possibility for learning even though these may be different (cf. Friesen, forthcoming). However, as seen in the two group works presented in this paper, this interactive obligation does not always lead to a collective argumentation in which a taken-as shared meaning is produced. In both groups, there are arguments that are brought forth but only in the first group these are brought forth collectively as can be seen in the excerpt. In the second group, the students do sometimes give an argument when a disagreement is verbalized, however, these are not taken up by the others and therefore no argumentation is brought forth collectively. In the future, these analyses will be compared with analyses of further group work in order to more clearly describe the patterns that enable children to bring forth and participate in collective argumentation.

### Acknowledgment

*As part of a research project focusing on investigative approaches to mathematics, a teacher in a Sámi school created an interdisciplinary teaching unit about patterns: skiing- mathematics- Sámi language. The 1–2 grade students painted their own patterns and they created patterns using their skis and poles in the snow. The analysis shows that the students developed their rules for what constitutes a pattern when the context changed from classroom work to skis on snow. One more aspect of pattern is focused: Sámi languages do not use any overarching term for pattern. At least three words are needed to cover the meaning of pattern in the mathematics curriculum.*

*Keywords: Pattern, hearva, language, Sámi upbringing, skiing.*

### Introduction

This paper presents an analysis of an investigative teaching unit, which focuses on *patterns* related mainly to the students' local culture and some physical activities. Regarding *pattern* as mathematical concept(s), two aspects of language are highlighted, a) relations between Indigenous (Sámi) language and majority (English and Norwegian) language and b) how students express their conceptions of *hearvvat* (patterns) in paintings and through their physical activities. Unjárgga oahppogáldu/Nesseby oppvekstsenter/Unjárgga centre of education is a mixed age school where the students have either Sámi or Norwegian as their first language.<sup>1</sup> Sámi is the first language of the teacher and the students in this paper. Sámi schools, like Unjárgga oahppogáldu, have to provide an education that is based on Sámi culture, language and social life (Sámediggi, 2017). As part of the research project SUM (Coherence through inquiry based mathematics teaching), the school develops investigative teaching units in mathematics from kindergarten to grade 10. Outdoor schooling is on the school's regular program. During a SUM meeting with teachers and the researcher, Anne, Lisbet got the idea of an open task where the students investigate skiing patterns they create in snow. She argued, "... I could work with patterns with skis. They could investigate patterns, because that is an open task..." (Transcript from conversation, 18.06.2018). In January 2018, students in grades one and two carried out an interdisciplinary teaching unit skiing - mathematics - Sámi. Lisbeth teaches mathematics and Sámi language for grades 1–2, so she often works interdisciplinarily with these subjects.

Trinick, Meaney and Fairhall (2016) point out that revitalization and maintenance of Indigenous language, including the teaching of mathematics, is insufficient unless cultural knowledge is also revitalized and maintained. The teaching unit considers their point, and thus mathematics, language and culture are intertwined in the teaching unit. According to Vorren (1995), there are several findings

---

<sup>1</sup> Sámi and Norwegian languages are equal in the Norwegian municipalities governed by the Sámi language act.

of ancient Sámi skis from the Unjárga area. One of these, the Mortensnes ski, is two thousand years old, so skiing has strong roots in the students' local culture.

Zazkis and Liljedahl (2002) point out, that patterns are the heart and soul of mathematics, but the exploration of patterns does not always stand on its own as a curricular topic or activity. According to the national mathematics curriculum's competence aim for grade 2, the students shall be able to "make and explore geometric patterns... and describe them orally" (Ministry of Education and Research, 2013). The teaching unit in this paper is about students' understanding of geometrical patterns. The teacher and the researcher communicate in Norwegian, while the teaching unit's language is North Sámi. Sámi culture and languages has a variety of pattern concepts, related to meaning and context. There is no overarching concept of pattern. Germanic languages, on the other hand, like English and Norwegian, use *pattern* and *mønster*, respectively, as overarching concepts.

Students' exploration of patterns/*hearvvat* in snow is the teaching unit's main mission. *Hearvvat* is a new concept for many of the students and the teaching unit opens with *hearvvat* in contexts related to clothes and fabrics. One goal is to provide the students with experiences of investigative approaches to mathematics, related to local culture. An additional goal is for students to develop their understanding of *hearvvat* through oral reasoning and reflections. The research question is; how can students' investigations of patterns in different contexts contribute to their conception of pattern? The data is a) an audio recording of teacher Lisbet's narrative about the teaching unit and b) posters with the students' work. The teaching unit includes five steps in total; two preparatory lessons that focus on patterns in fabrics, on clothes and in students' paintings, two outdoor skiing lessons and one reflection lesson in the classroom. The preparatory lessons intend to provide the teacher with an overview of the students' previous knowledge and to create a common idea of *hearvvat*.

### **Sámi languages and Sámi upbringing**

Fishman, Gertner, Lowy and Milán (1985) point out that language itself is a part of culture and every language becomes symbolic to the culture with which it is intimately associated. The Sámi is an Indigenous people who live in northern Scandinavia and in the Kola Peninsula of Russia. There are ten different Sámi languages and Sámi culture can be described as diverse. This paper refers to North Sámi language. Sámi handicraft, *duodji*, is a powerful identity marker and generator of many traditions, such as language, social relationships, customary rules etcetera (Helander-Renvall & Markkula, 2017). The traditional Sámi livelihood of hunting, fishing, trapping and reindeer husbandry are important for sustaining Sámi culture and language (Keskitalo & Määttä, 2011). Skiing is an old Sámi tradition and the art of skiing originates from the ancient Sámi hunting, fishing and trapping culture (Birkely, 1994; Vorren, 1995). Skis are among the eldest relics of culture from Sámi settlements, and variations in landscapes and snow conditions caused the development of a variety of skis and sleds, for which the Sámi languages developed a wide nomenclature of expressions (Vorren, 1995). Due to the Norwegianization process (Heidemann, 2007) many of these words are not in daily use any more. In Unjárga today, Norwegian terms for skiing are commonly used in the students' Sámi language. The teaching unit introduces students to Sámi skiing concepts.

The main goal of traditional Sámi child rearing is to develop independent individuals who can survive in a given environment; and to give the children self-esteem and zest for life and joy (Balto, 2005).

The focus is on the learning process and less on teaching, so evidently experience-oriented learning is favoured. Trial and error is important for the learning process. As for skiing, knowing how to ski uphill and downhill is learned through trial and error and from the support of grown-ups and the older children. Keskitalo and Määttä (2011) developed a framework for Sámi pedagogy, where Balto's (2005) work has the central position. Upbringing is based on story-telling, connection with nature, and independence. Sámi pedagogy is based on a holistic and constructivist idea of learning. Strengthening the Sámi language is a core factor in the framework of Sámi pedagogy (Keskitalo & Määttä, 2011). All students should have the possibility to develop as language users at their own pace.

According to Balto (2005) as well as Keskitalo and Määttä (2011), autonomous students is a central theme in Sámi upbringing; the role of the teacher is to be advising, guiding, and trusting, while the students' role is to be active, flexible, and autonomous. Children should be provided with opportunities to find information and learn in nature and other places outside the classroom. Skovsmose (2001) underlines the importance of leaving the traditional mathematics textbook-based lessons when the teacher aims to support the students' autonomy. A move towards more investigative approaches can cause the students to be acting subjects in their learning process. The teaching unit allows the students to learn at their own pace and to develop as autonomous individuals.

### ***Mathematisation of hearvvat or patterns***

To mathematise phenomena from a non-mathematical or insufficiently mathematical matter, like skiing, means learning to organize it into a structure that is accessible to mathematical refinements (Freudenthal, 1991). Mathematising patterns in cloth, gloves, and skiing involves representing phenomena from these contexts by mathematics, for instance as drawings and geometrical figures, or representations by more or less mathematical concepts, expressed in different languages. However, topics related to Sámi culture exist because they are intertwined with cultural context; they cannot just be mathematised as if they exist independently from context. This is an important issue to consider for researchers and teachers with non-Indigenous backgrounds. Lakoff and Núñez (2000) point out, that mathematical symbols are just symbols and not ideas. The intellectual content of mathematics lies in its ideas, not in the symbols themselves. Symbols are representations of ideas that often can be expressed in more than one way. In this paper, we present students' descriptions of mathematical ideas; students' own *hearvvat*, patterns, with a focus on their drawings and their words.

Context plays an important role when translating the English word *pattern* into Sámi. Repeating patterns in woven bands and around gloves' wrists, like in Figure 1, are called *hearvvat* in Sámi. According to Nielsen's (1932/1979) dictionary, *hearva* means finery, adornment, and ornamentation. He presents two more Sámi words for pattern; *minsttar*, which means pattern, model or template, and *girje*, which has two meanings. *Girje* means a spot of another colour (on an animal). In plural form, it means coloured ornamental patterns, like *girjefáhccat*; gloves that are patterned all over. However, the word *girje*'s second meaning is *book*. According to a more recent dictionary (Kåven, Jernsletten, Nordahl, Eira & Solbakk, 1995), *hearva* means decoration, trimming, or embroidery, while *minsttar* means pattern or formula, and *girji* means book, letter, or spot. So, in total there are three different North Sámi words that can mean *pattern* in English. The North Sámi version of the mathematics curriculum (Ministry of Education and Research, 2013) consequently uses *minsttar* for pattern

(Norwegian: *mønster*). *Minsttar* may work for number patterns, but not for the geometrical patterns in the teaching unit. Lisbet uses the word *hearva* in the teaching unit. She discussed the question of using *minsttar* or *hearva* with Harald Gaski who is a professor in Sámi culture and literature. He too found *hearva* to be more appropriate for *pattern* in the teaching unit's contexts. Gaski (1998) describes the lyrics in the traditional Sámi song, *luohti*, as something that follows a pattern. In that context, he uses the Sámi word *girji* for pattern. *Pattern* is a central concept in mathematics, but the literature has not problematized the Sámi translations of it.

**Figure 1. Example of *hearvafáhcca*: The patterned Unjárgga/Nesseby glove (photo: Lisbet Hansen)**

Sámi languages do not use overarching terms to the same extent as Norwegian and English do, they have chosen different ways of expression (Fyhn, Eira, Hætta, Juuso, Nordkild & Skum, 2018). This should be an important issue to consider for mathematics education in Scandinavia. Bishop (1990) warns that it is very difficult for anyone conditioned to the western way of naming and classification to imagine that there exists other ways of conceptualizing and using language. McMurchy-Pilkington, Trinick and Meaney (2013) point at the importance of debating standardization of terms and the place of dialectical differences, in the development of Indigenous mathematics curricula. It could be that *hearva* and *minsttar* are used differently in eastern and western parts of the North Sámi area.

### The teaching unit's preparatory steps

The first step of the teaching unit was based on a collection of patterns that the teacher brought to her classroom; Unjárgga gloves as shown in Figure 1, pieces of fabric like the examples in Figure 2a and 2b, an apron, homemade woollen socks, and a *holbi* from an Unjárgga *gákti* (the bottom part of the local Sámi dress) as shown in Figure 2c. Stars and candles in Figure 2a were the first items the

**Figure 2a. Stars and candles**

**Figure 2b. Stripes**

**Figure 2c. *Holbi* from Unjárga**

students managed to recognize and name here. The students' discussions lead to a common rule for what counts as a *hearva*; it has to be a system of colours. When asked to search for repetitions, everyone found something; for example red-green-red-green ..., square-rectangle-square-rectangle ... and star-candle-leaf-star-candle-leaf... After a while, one student pointed at two fabrics, claiming that one has *hearva* while the other has not. This student distinguished between what is *hearva* and what is not by a counterexample; that something is not *hearva*.

In Step 2, most of the students' work was autonomous. This is in accordance with Keskitalo and Määttä's (2011) description of Sámi pedagogy and with Balto's (2005) description of traditional Sámi child rearing. The students' task was to create and paint their own *hearvvat* and the teacher had no control of their choices. Every student created multiple paintings. The paintings in Figure 3 show how three students represent their ideas of *hearva*, pattern. Each painting shows a system of colours. Each painting also shows repetitions of something. The three paintings show repeating dots. The leftmost painting shows repetitions of blue dots; some dots are only blue and some dots have a brown circumference. The two other paintings also show zigzag patterns, this could be related to the zigzag pattern in Figure 2c, which is named *njunnesuorránat*. Considering that the Sámi word *hearva* means *finery*, *adornment* and *ornamentation* in English, it is reasonable to expect that the students include colours as a property of *hearva*. The other paintings also showed systems of colours and repeating items.

Figure 3. Three painted *hearvvat*

### Work with *hearvvat*, patterns, in snow

Step 3 took place outdoor. When the teacher asked if the students could make any *hearvvat*, patterns, in the snow with their skis and poles, the answer was no. Then Lisbet skied around the schoolyard with the students following her trail. Pointing at the fresh ski trail, she asked if there were any *hearvvat*. This is interpreted to be a leading question, a support for those who had ideas they did not dare to present the first time they were asked. Several students answered no and no one objected. This is interpreted to mean that the students' conceptions of *hearvvat* did not include patterns in snow. Most likely it was limited to coloured patterns on clothes, fabric and paper. The students' rules for *hearva* included a system of colours. The white snow is just white; there is no system of colours. The teacher's aim was that the students developed their ideas of what constitutes a *hearva* to something independent of colours.

The teacher offered the students time for thinking. After a while, one student suggested that maybe the poles create *hearvvat* in the snow. Lisbet then asked whether the skis make any *hearva*. One student replied that the skis make lines, like the stripes in the fabric in Figure 2b. When you go skiing, you usually move forwards while the patterns and marks from your skis and poles appear behind you. One student expressed this as "Ovddes guvlui go čuigen šadde sárgát" [when you skied forwards, there appeared some lines] (Lisbet, transcript from conversation, 18.06.2018). In order to see what you have created, you have to look behind you. Children at school age are familiar with what ski trails look like. Students' investigations of skiing patterns also include investigations of how they move their entire bodies; they learn at their own pace, "In one way they investigate the *hearva* as well as the skiing technique... they have to try things out to see what happens", (Lisbet, transcript from

conversation, 18.06.2018). “They have to try things out”, means that the students are acting subjects in their learning process, as Skovsmose (2001) underlines. This is in accordance with Sámi traditional upbringing (Balto, 2005) and Sámi pedagogy (Keskitalo & Määttä, 2011).

Figure 4a. *Spiehččut*

Figure 4b. *Duolbmá*

Figure 4c. *Guolli*

Step 4 took place at the school's soccer field. The students were asked to create their own *hearva* in the snow. They explained their *hearvvat* to the others, and Lisbet captured photos of their work. Usually, the students use Norwegian skiing concepts when they speak Sámi, but now they have started using Sámi concepts like *spiehččut* (herringbone skiing) as shown in Figure 4a, and *duolbmat* (sideways uphill tramping) as shown in Figure 4b. When you perform skiing techniques like in Figure 4a and 4b, the outcomes are patterns in the snow. These patterns are named by the technique; by the way you move your body. So, the students' ideas of *hearvvat* were represented by how they moved and by the marks made by their skis and poles. At the end of the lesson, the teacher and the students looked at all the patterns. The students explained in their own words. The two students in Figure 4c first made a *dávgehápmi* (curved shape) and *njuolga sárggá* (straight line) and then *rieggát* (rings). The result was *guolli* (a fish). One student said, “When I skied forwards, the result was straight lines.” In order to bridge the students' daily Sámi language and their mathematical language, Lisbet supplied their choice of words with mathematical terms like *circle*.

The drawings and texts in Figures 4a–c present outcomes from Step 5; a reflection lesson that took place in the classroom. The students were presented to A4 photos of their snow *hearvvat*, and they recognized the photos and discussed their *hearvvat*. Each student chose one photo, made a drawing of the *hearva* and wrote a text for that drawing. The teacher had no control of the students' choices. Some of them needed assistance in writing down their words related to the photo; they asked how to spell some of the words and the teacher then showed them before they wrote on their own. The students were active and autonomous, while the teacher's role was supporting and trusting; this lesson was in line with Sámi pedagogy. The first graders needed more assistance in writing than the elder ones.

## Closing words

The conversation between the teacher and the researcher revealed that the teaching unit provided the students multiple experiences with investigative approaches to mathematics related to their local culture. Students were acting subjects in their learning process by creating their own *hearvvat*, patterns in different contexts. Their development of rules for what is a pattern was guided by the teacher. The students' first rules for what is *hearva*, pattern, was related to clothes, fabrics and paintings; it had to be a system of colours and it had to be repetitions of something. When the context changed to skiing, the students at first found no *hearva*. Maybe that is because there were no contrasting colours or maybe that is just because the context changed. The teaching unit caused a development of the students' concept of *hearva* such that it does not have to include different colours. The teaching unit highlights the challenge students meet when they move from one context to another; students do not automatically transfer knowledge into a new context. The analysis also revealed a need for discussing the mathematics curriculum's choice of Sámi terms for *pattern*. It turned out that the three different Sámi words *hearva*, *girji* and *minsttar* all can be translated to pattern. These words are related to different cultural contexts. This may have influenced the students' ideas when they made up their rules for what a *hearva* is. More research is needed on the meaning of these words in order to prevent misunderstandings between teachers, students, and parents, not to mention those who write textbooks and curriculum texts. The teaching unit also appreciates and strengthens local Sámi language; the students used Sámi concepts for skiing techniques that they usually refer to with Norwegian concepts in their daily Sámi language. An interesting follow-up study would be to interview Lisbet's students one year later in order to see what words they use, when describing what is meant by *hearva*, and what is meant by *minsttar*, the curriculum's word for pattern.

## Acknowledgements

# Centripetal and centrifugal forces in teacher-class dialogues in inquiry-based mathematics

Ingólfur Gíslason

University of Iceland, Iceland; [ingolfug@hi.is](mailto:ingolfug@hi.is)

*In this report I examine classroom dialogue in the practice of a teacher who is explicitly committed to a dialogical, inquiry-based approach to teaching mathematics. Of primary interest are the ways in which the dialogues on the mathematical tasks are in continual tension, alternately being pulled towards and pushed away from a proper mathematical discourse, as seen from my perspective as a mathematics educator and an observer of the lessons in the classroom.*

*Keywords: Classroom communication, discourse analysis, inquiry-based learning, dialogism.*

## Introduction

If students are to gain a command over mathematical discourse, they need to practice talking mathematics. It is well documented that in traditional classrooms it is predominantly the teacher that talks mathematics, and the IRE (initiation- (short) response-evaluation) format of teacher-student interaction is ubiquitous. Many studies show the meaning making potential of inquiry-based teaching-learning, where the students do more of the mathematical talk (e.g., Boaler, 2002; Goos, 2004; Lampert, 1990) but there is little research on mathematical discourse in inquiry-focused classrooms on the upper-secondary level. I report here on my longitudinal case study of inquiry-based teaching-learning in the practice of an upper-secondary level mathematics teacher working in a challenging classroom in Iceland. I analyse teacher-class dialogue on realistic tasks from a dialogical perspective, showing how the concepts of the centripetal and centrifugal forces (Bakhtin, 1981) may be used to describe and understand the dynamics of the dialogue.

## Theoretical perspectives and prior research

In line with discursively focused research, I consider mathematics learning as the increased command of mathematical discourse, a progress from discourse confined to informal everyday language towards the command of a more advanced and formal mathematical discourse – the culturally specific, tool-mediated, historically established ways of communicating that competent users of mathematics use (e.g., Sfard, 2008; Chapman, 1997; Barwell, 2016; Roth & Radford, 2011). Dialogues are the primary objects and units of analysis, and I consider dialogue, following Linell (1998, p. 13) as “interaction through language (or other symbolic means) between two or several individuals who are mutually co-present”. A dialogue is a chain of utterances, which are the complete meaningful contributions persons make to the dialogue. An utterance is always a response to what has gone before, addressed to someone(s) in anticipation and expectation of future responses. Utterances contain intentions, emotions, evaluations, which are dependent on context, and sometimes conveyed through means such as tone and gestures. From a dialogical viewpoint, utterances do not have fixed meaning but they do have partly open meaning potentials rooted in culture, history and ideology and the specific speech genres and social languages they belong to. Communication does

not presuppose or produce total shared-ness of meaning; rather it consists in people's continued and on-going attempts to expose and test their understandings (Linell, 1998).

In the inevitable difference of two or more perspectives inherent in each utterance Bakhtin identifies a tension between a centripetal force towards uniformity, a shared and common meaning, and a centrifugal force towards diversity of discourse, the meanings made in particular situations by particular persons (Bakhtin, 1981). These forces are depicted in Figure 1 as opposite directed arrows, as we imagine the dialogue happening on a boundary surrounding a shared meaning.

**Figure 1: Forces in dialogue**

From this Bakhtinian viewpoint I consider the mathematics teacher as working towards the (relative) uniformity of mathematical discourse, while the students make and express more diverse meanings, as they are imbued with language, values and views from their social worlds. When people attend mathematics classes and sense it as a painful, or even meaningless experience, this is because the words of the teacher and the textbooks do not resonate with them and do not move them. Following Bakhtin (1981) we say that the discourse lacks inner persuasiveness. In this all too familiar case, students do not make the discourse their own, it is alien to them. They behave as factory workers although they are not producing things of value for capitalist owners. Rather, they are producing strings of symbols, that are as such of no market value, in order to prove their own value (as good students and future productive citizens). Research published on mathematics in secondary school in Iceland points to a dominance of this kind of alienated form of mathematics work: an emphasis on symbolic manipulations but little emphasis on meaning and no, or very little, exploratory work; the textbook dominates and the class sessions are characterized by teacher transmission and students sitting at desks solving exercises individually (Bjarnadóttir, 2011; Gunnarsdóttir and Pálsdóttir, 2015; Jónsdóttir et al. 2014).

## Research method

The setting of the study is an upper-secondary school classroom in which most of the students have a history of very low achievement in mathematics. In order for me to make sense of the classroom dialogues I was present in the classroom the whole semester-long course as a mostly passive observer, concentrating on capturing audio and video of the speaker(s) who have the floor at a given time. I attended the class with a videorecorder in 32 of the 39 classrooms sessions of the course which lasted from late August to December 2012. Although my role was mostly passive, I did interact with students, discussed the situation of me being present in the classroom, asking for permissions to record a pair or small group conversation and sometimes responding (usually rather minimally) to

questions about the mathematics tasks. For the purposes of this paper I focus only on the three lessons where there was a public whole-class discussion about realistic mathematics tasks. The tasks are all teacher translations of tasks from Swan, Pitts, Eraser, and Burkhardt (1985). A video analysis tool, Transana, (Fassnacht & Woods, 2012) was used to transcribe video segments synchronously.

I coded the teacher-student dialogues using open coding, drawing on a grounded theory approach (Charmaz, 2006) aided by the dialogical principle that it is the participants' responses that provide evidence for the meaning of a prior utterance. Still, it should be borne in mind, as Bakhtin argues, that “understanding a dialogue as a researcher implies participating in that dialogue as a ‘third voice’.” (Wegerif, 2007, p. 21). This means that I, as the researcher, make sense as the other participants, anticipating, responding, and creating tentative sense in my own way, based on my cultural background and personal history. After a few iterations, recurrent themes emerged that seemed to capture the different ways the participants responded to the tasks presented, thus contributing to different types of dialogue. In the following I present purposefully selected short sequences of dialogue to illustrate the types. These fragments are then analysed in more detail in order to bring further attention to the centripetal and centrifugal effects of the contributions to the dialogue.

In order to make the reading of the fragments feel natural, the students have all been given unique pseudonyms.

## Results and discussion

Inspired by Bakhtin's ideas of learning as adopting words (and gestures, phrases, drawings and all means of communication) of others and using them with one's own intentions with varying degrees of “our-own-ness”, and his notions of centripetal and centrifugal forces operating in a dialogue, I classified four types of dialogue. Two of the types refer to distancing in dialogue: *the alien word* (11) and *irony* (29) and two are types of accepting dialogue: *authentic real world* (123) and *emerging mathematical* dialogue (48). The numbers in brackets indicate a count of utterances contributing to a types' appearance to give some indication of their relative frequencies, although an utterance does not always contribute clearly to only a single type of dialogue. The first three types function more centrifugally than centripetally.

To illustrate the most frequent type, *authentic real-world* dialogue, I present a fragment of a dialogue on the question of the nature of a general relationship between the weight of a person and her high-jump ability. The task text states: “Suppose you were to choose, at random, 100 people and measure how heavy they are. You then ask them to perform in 3 sports; High Jumping, Weight Lifting and Darts. Sketch scattergraphs to show how you would expect the results to appear, and explain each graph, underneath. Clearly state any assumptions you make.” The following sequence of utterances starts after the teacher has drawn positive coordinate axes on the whiteboard and has exchanged a few turns with students about the nature of the task.

Ari: Like, like, the body weight shouldn't matter crucially, like in high jump. [Eagerly]

Teacher: What.

Ari: Like the guy who is one ninety and a guy who is one sixty. A guy who is one ninety could be heavier than the guy who is one sixty, isn't that right?

- Teacher: But if you have two guys that are one ninety and one is heavier and the other is lighter, who
- Ari: The lighter guy.
- Teacher: What do you think about that? [Addressing the class]
- Bjarni: Not necessarily.
- Ari: It depends on the technique and where he is muscular.

The request for a relationship immediately provokes a comment from Ari that a functional relationship between body weight and height jumped is not appropriate, body weight is not the most important thing to consider in this context. He also introduces the theme of the height of the imagined people and the relations between those and their body weights. This is not at all mentioned in the task but may be related to the general knowledge that taller people usually are better at the sport of high jump and because the heights of people were a theme of a task these students worked on earlier. In their apparently sincere discussion about the context, they pull the theme of the dialogue from mathematical representations to sports and body types which I understand as a centrifugal force away from the core of mathematical discourse. Ari and the other students are perhaps understandably confused by the realism of the task. They do not know that they are expected to focus on an abstract (and arbitrary) relationship and that for the mathematics teacher it is not important what is important for success in high-jumping. The teacher attempts to pull the dialogue back, trying a what-if question where the real-world factors are controlled, trying to bring the attention to the variables of mathematical interest. The students seem unaffected by the centripetal force of the teacher's utterance and go off on a further tangent. There followed an animated discussion about important factors relating to the sport of high jump, while the intended task of representing a statistical functional relationship by a scatter graph receded from the dialogue. It is open to question whether some amount of this type of dialogue could actually be a necessary precursor to emerging mathematical dialogue. It can be seen as building emotional connections between teacher and students, showing that their thinking and perspectives are valued and not brushed aside.

The *alien word* was infrequent as a type of sustained dialogue. This is because usually when students experience mathematics as alien to them, they are simply silent, or show their alienation indirectly. They might for example choose to look at irrelevant computer programs, play with their phones, or talk with peers about social matters. Only rarely does the theme of the alien word become explicit in dialogue.

- Teacher: Are you all following what we are doing? (...) Do you think this is mathematics?
- Einar: I think this is unnecessary bother.
- Teacher: Unnecessary bother?
- Einar: Yeah.
- Gunnar: It's philosophical mathematics.

Anna: If you think about it in that way, see, that this is the weight plus the weight, but like in weightlifting, I don't feel we are talking about mathematics, rather talking about sports than mathematics.

The first utterance in this sequence was a response of the teacher to the situation that the majority of the student group seemed to be confused by the discussion and had ceased to participate in the dialogue. He tries to pull the class into a meta-discussion about the nature of mathematics and mathematics class, but Einar rejects the question on the grounds that it is unnecessary and a bother. Mathematics to him does not include students' own consideration of real-world complexities. His contribution also indicates that what is important is the amount of bother expected of him. He evaluates bother negatively. Gunnar partially supports Einar in that this is a special type of mathematics. These contributions are centrifugal. Anna makes an interesting comment that resonated with me, as she expressed what I was thinking about the dialogue up till then. It was about sports and not about mathematics. In a way this contribution is centripetal in two ways. She gives a reasonable answer to the teachers' question (she is affected by his pull) and criticizes the discussion on grounds that (in my theoretical terms) it is an authentic real-world dialogue, which she considers (again, in my theoretical terms) to be centrifugal and not conducive to mathematical discourse.

*Irony* means saying one thing and meaning another. To illustrate irony as a type of dialogue, there follows a dialogue on a task the point of which is to investigate the relationship between the number of workers and the time it would take them to finish a task. The task text asks the student to sketch a graph describing the time it would take to harvest a field of potatoes, depending on the number of potato pickers. The task is presented with unmarked axes in the positive direction, with the label "Total time it will take to finish the job" on the y-axis, and "Number of people picking potatoes" on the x-axis. The students were asked to work on this in their seats, the task being in their text. One student soon exclaims: "I don't understand" and the teacher goes to the whiteboard in front of the class.

Teacher: We are going to think about ... can we maybe assume. What are we going to say that one person would take long to harvest this field?

Siggi: How big is this field?

Teacher: Well, you just decide.

Siggi: Okay, it's just one meter.

Teacher: One meter. [Disbelief in the voice]

Siggi does not answer the teacher's initial question but asks a different one, and I assume he thinks this is an important question to answer in order to finish the task (in fact in the abstract mathematical model this is completely irrelevant and does not need to be answered). The teacher does completely shut down this line of inquiry but indicates a choice available for the student even if it does not really matter what the choice is. Siggi then responds with an extreme example that does not make sense if interpreted in the context of the real-world. Double-voiced discourse is a discourse that has "a twofold direction" (Bakhtin, 1984, p.184); it is directed toward someone else's discourse or toward someone else's position. One interpretation of the student's response is that that the task does not make sense

to him or that he is not committed to make sense of it, that the question (and therefore the teacher) is silly and his answer is going to be silly; that the question is too open, and he will test its boundary. It contains an evaluation of the whole situation; it is an ironic rejection to engage authentically in dialogue. The teacher's final utterance in this sequence is an echo, a repetition of the prior utterance, but in a falling tone, with a different pattern of stress on the syllables. I interpret this as an expression of disbelief, and as if to say, "that is ridiculous, you know it, reconsider your suggestion". An alternative interpretation could have been possible: in mathematics it can be informative to specialize (try out specific values in a general expression) with extreme values (not infrequently 1 or 0). The student's ironic assumption could have been taken as an attempt to specialize to see what happens in an extreme instance. However, in light of the effect of the utterance on the teacher and the dialogue closing up at this point, it seems clear that the teacher takes Siggi's contribution to be ironic, and some form of rejection to take the task seriously.

To illustrate the *emerging mathematical* type of dialogue I present a fragment where students are working further on the potato picking task. They have been asked to draw a graph of the relationship between the number of workers (x-axis) and time it takes to harvest a potato field. The teacher has circulated and comes to the whiteboard and says that he has seen "a lot of these" and draws a straight line segment with y-intercept at 100 and a negative slope, but not touching the x-axis. The students' drawings are consistent with the fact that they have not had much (or any) experience with other kinds of graphs in their mathematics in school. Their repertoire of graphs consists of straight lines, as this is what a graph means to them, and they use it to express increasing or decreasing functions. After some students confirm that this is how it is and the teacher acknowledging "in a way, approximately" expecting something more, there follows:

- Katie:            You need to know how many people you want at the end.
- Teacher:        Do we?
- Katie:            Yes.
- Teacher:        Can't we just...
- Katie:            If you have the time, you know, the maximum time ... how many people are you going to have in the end.
- Siggi:            We're going to have thirty people.
- Katie:            Okay, if you are going to have thirty people you just do a hundred divided in thirty, then you have the time a single person has.
- Teacher:        Okay, you gave us some, what, four hundred eighty minutes? But can we do this like ... in mathematics we can add people infinitely. Although there might not be enough room in the field for everyone.

First, Katie expresses that for the task to make sense and be solvable we need to know the maximum number of people. This is reasonable from a real-world perspective, as it would be impossible to have an infinite number of workers, or even a too large number of people. After a contribution from Siggi, Katie tries to express the relationship time divided by number of workers, getting the "time a single

person has” where it would be correct to say that this is the total time it takes, but indeed this is also the time each single worker would have to work. My interpretation is that Katie’s answer confused the teacher or that the teacher interpreted her as thinking that the workers would work in succession, one at a time. Therefore, he does not build directly on her contribution but returns to a particular number (480) of minutes mentioned long before in the dialogue, and to the question of whether we need to know the maximum number of workers. He indicates that they could be infinitely many, because such is mathematics, even if not realistic.

After the sequence above, there follow over a hundred turns where the teacher and the students slowly clarify the meaning of the graphical representation, the role of the axes, and what the points refer to, they discuss the assumptions needed to make a model, and then gradually move away from a linear model towards a reciprocal one, and at last some students articulated this by themselves, incorporating the model into their own discourse. Here then, the teacher and the student group continually exposed and tested their understandings and perspectives against each other, and the centripetal force was strong enough to keep the dialogue mathematical, bringing students closer and closer to shared mathematical discourse.

### **Concluding remarks**

The students seem to orbit around mathematical concepts while the teacher tries to pull them into a more mathematical discourse. This is the dominating feature of the first three types of dialogue above. The authentic real-world type of dialogue is of particular importance. The students show sincere interest and enthusiasm for the real-world situations in which they recognise important features of the situation. Unfortunately, these features are tangential to the mathematical discourse the teacher tried to draw them into and may result in the dialogue drifting away from mathematical discourse.

To make sense of a mathematical task, the students need to attend to the context and not suspend sense making, while at the same time it also demands that the context is downplayed and not taken too seriously. In that way, the official mathematical discourse itself is double voiced and ironic. It does not really care about the high-jumping ability of people and what factors are most important to consider when estimating or predicting these abilities. It only cares about using graphs and functions to represent idealized phenomena. The teacher needs to convey this and then slowly lead students to productive ways to make mathematical sense, building on the sense made previously. For example, he suggests particular numbers (specializing) to think about or gently challenges the students’ answers while often recognizing that they are onto something. In this way the mathematical discourse becomes internally persuasive, at least for some students. We saw how the teacher and the students slowly achieve a more shared understanding in the dialogue in the last example, as it slowly approaches a more mathematical discourse, through constant exposure and testing of understandings.

## **The importance of a meaning-related language for understanding multiplication**

Daniela Götze

Technical University Dortmund, Germany; daniela.goetze@tu-dortmund.de

*Multiplicative thinking is much more than recalling number facts. Furthermore, it is much more than repeated addition. It is about links and relationships and knowing how multiplicative ideas are connected and why multiplicative grouping processes work as they do. Supporting this conceptual understanding of multiplication among underachieving primary school children is the goal of a single-case intervention study presented in this paper. These children were fostered in a language sensitive way placing emphasis on the relationship of different multiplicative representations and a meaning-related vocabulary associated with this operation. The in-depth analysis of an individual learning trajectory of a low-achieving child shows that the progress may depend on whether and to what extend the meaning-related vocabulary becomes the vocabulary of thinking for these children.*

*Keywords: Multiplication, mathematical concepts, verbal learning, low achievers.*

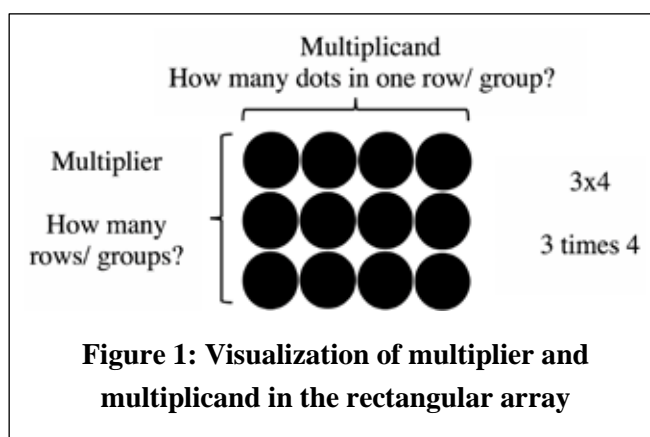

During their first years of school, children should not just be able to execute multiplication tasks, but more than anything else, should also understand them in terms of content as well. For primary school children who have not acquired a multiplication concept it is much more difficult to achieve higher learning targets (e.g. Downton & Sullivan, 2017; Moser Opitz, 2013). This is particularly the case because an understanding of multiplication represents a fundamental requirement for understanding further learning contents such as proportionality, algebra, fractions, decimal numbers, percentages... (Downton & Sullivan, 2017). In this respect, it is by now accepted that the development of a conceptual understanding for the multiplication is of far greater importance than learning the times tables off by heart (Gaidoschik, Deweis, & Guggenbichler, 2018; Moser Opitz, 2013).

### **Theoretical background: Fostering a conceptual understanding of multiplication**

Kilpatrick, Swafford and Findel (2001) define the conceptual understanding as an understanding of mathematical concepts, operations and relationships. A mathematical concept is said to be understood when it constitutes a part of the mental knowledge and is said to reach a higher level if it is interconnected with existing knowledge and can be used to solve diverse mathematical tasks (Kilpatrick et al., 2001). What this means for the multiplication specifically is that children need to understand that cardinal quantities are combined with each other, wherein, formally speaking, the multiplier represents the frequency of the cardinal quantities and the multiplicand represents the size of the cardinal quantity (Figure 1). Both factors are therefore not equal (Downton & Sullivan, 2017). However, multiplication is often introduced in the form of repeated addition, which is the preferred strategy used to solve the multiplication tasks particularly in low-achieving children (Moser Opitz, 2013). But this equating of multiplication with repeated addition leads to an incorrect understanding of multiplication (Downton & Sullivan, 2017), in the case of addition, both numbers represent a respective quantity, which can be cardinally translated and merged. Multiplication, however, means to coordinate interrelated units.

If children tend to equate the multiplication with repeated addition or with count-by sequences (“four, eight, twelve”) – as another typical strategy of low-achieving children – this differentiation between multiplier and multiplicand does not become clear. Furthermore, the knowledge in relation to associative and distributive contexts is not accessible to them. Additionally, those solution strategies are very limited and cannot, for example, be used when it comes to fractions or decimal numbers (Downton & Sullivan, 2017).

In this respect, many researches have shown that a conceptual understanding of multiplication instead of automaticity needs to be fostered in the first place. Many of these studies take a strategy-training approach (e.g. Gaidoschik et al., 2018; Woodward, 2006). Particularly remarkable is that predominantly low-achieving children – even after a strategy-training – seldom use derived-fact strategies compared with normal-achieving children (Zhang, Xin, Harris, & Ding, 2014) or have difficulties in deriving (Gaidoschik et al., 2018). On the one hand, this can be traced back to the fact that the use of decomposition strategies is very working-memory demanding and low-achieving children are characterised by their limited working memory (Zhang et al., 2014). On the other hand, the cause can be seen in an insufficient conceptual understanding of multiplication (Downton & Sullivan, 2017). These children do not seem to have fully understood what phrases such as “three times four” or “four multiplied with three” actually mean. This means that perhaps the differentiation between multiplier and multiplicand needs to become more obvious for these children as a central basis for developing derived-fact strategies. However, current research projects have repeatedly shown that the transition from the repeated addition or count-by strategies to the understanding of multiplication is a – if not *the* – critical obstacle to the conceptual understanding of multiplication especially in the case of low-achieving children (e.g. Zhang et al., 2014). Therefore, in future research, this should be the starting point to identify which steps could help children overcome this critical obstacle. But if phrases like “three times four” or “four multiplied by three” are initially of no meaning to these children other phrases such as “three groups of four”, “the four three times”, “three rows of four columns each” may support the development of a conceptual understanding. It has still not been researched sufficiently whether and to what extent this “basic meaning-related vocabulary” (Prediger & Wessel, 2013; Pöhler & Prediger, 2015) supports a conceptual understanding of multiplication in low-achieving students. In terms of increasing a conceptual understanding of division among low-achieving children, it has been shown that the understanding of division can be fostered with the help of meaningful verbalisations such as, for example, “12 divided by 4 means how many fours fit into 12” (Götze, 2018). Whether or not students benefit from such support seems to primarily depend on whether this meaning-related vocabulary will become the students’ language of thinking (Pöhler & Prediger, 2015). This means that in the course of such fostering, it might primarily depend on if and to what extent the students are able to internalise these verbalisations and how they can contribute to the forming of mental models. In this respect, the single-case research project presented in this paper focuses on the following research question:

*How does a language sensitive support of multiplicative grouping promote a conceptual understanding of multiplication in low-achieving children?*

## **Methodology of the study**

The study presented in this paper pursues the goal of conducting a detailed in-depth analysis of the learning processes for the development of a conceptual understanding of multiplication among low-achieving children. Therefore, the study is structured as a single-case didactical design research (Pöhler & Prediger, 2015). The data presented are from the first circle.

A total of ten pairs, consisting of one normal- and one low-achieving child, were assisted by one trained preservice elementary teacher. The cooperative setting was selected because the discursive negotiation of meaning among heterogeneous children has proven itself to be very beneficial for learning in other studies as well (Götze, 2018; Zhang et al., 2014). The pairs of children were provided with fostering help on a total of four remedial lessons. Each of these remedial lessons lasted approximately 25 to 30 minutes. They were provided by three pre-service teachers who had been intensively trained beforehand.

At the time of the study, the participating children were in the third grade in a German primary school and had already learnt multiplication in their second year in school. As a side note, in Germany the rows of times tables are determined by the second factor. So,  $1 \times 2$ ,  $2 \times 2$ ,  $3 \times 2$ ,  $4 \times 2$ ... are second-row tasks,  $1 \times 5$ ,  $2 \times 5$ ,  $3 \times 5$ ,  $4 \times 5$ ... are tasks from the fifth row. For these children, the tasks  $3 \times 4$ ,  $3 \times 6$ ,  $3 \times 9$  belong to different rows.

Based on the review of the current research, these children were fostered in a language sensitive way placing emphasis in the relationship of different multiplicative representations (concrete, iconic and symbolic representations) and a meaning-related multiplicative (not additive) vocabulary associated with this operation. For doing this, the following central learning and diagnosis steps were applied in order to foster a conceptual understanding (based on Pöhler & Prediger, 2015):

- Step 1: Informal thinking starting from students' resources.
- Step 2: Focusing meaning-related vocabulary for understanding multiplicative grouping and connecting this vocabulary with concrete, iconic and symbolic representations.
- Step 3: Independent use of the meaning-related vocabulary.
- Step 4: Use of meaning-related vocabulary in order to initiate decomposition strategies.

Especially in the second support unit (step 2) the children had to find reasons for the assignment of iconic rectangular arrays and symbolic terms. At the same time, the multiplicative understanding was addressed directly: "three times four" means that there are three fours or there are three groups, each of which has four in one group. The children should always explain this relationship: Where do you see the number of the groups? Where do you see the group size? Subsequently, during the third support unit (step 3), this understanding was deepened further through more game-based assignments (for example pairs card games). The children were furthermore required to name the matching terms for orally described rectangular arrays. In the case of difficulties, they were allowed to lay the rectangle. Then, the children should lay rectangular arrays selected by themselves with manipulatives and describe these in a similar fashion. The children were repeatedly asked to interpret the group

number (the multiplier) and the group size (multiplicand) in terms of content. The constant alteration between language reception and language production was intended to form mental models. During the transition to the decomposition strategies in the fourth support unit, the children needed to think about which arrays could be laid next to each other and which overall term would match. They were given some rectangular arrays, which they could distributively combine in sometimes different ways. What was important here once again was the fact that the children had to explain why, for example,  $3 \times 4$  and  $2 \times 4$  together make  $5 \times 4$ , but also why  $3 \times 4$  and  $3 \times 1$  together make  $3 \times 5$ . This required them to pay attention to the differentiation between multiplier and multiplicand, as well as to verbally describe their meaning and importance. This makes it absolutely necessary to have mentally understood the previous actions carried out on the rectangular arrays or to be able to fall back on these once again.

Therefore, the following section gives an insight into the learning pathway of the low-achieving child Ilay. The goal of the analysis is to ascertain under which conditions the use of meaning-related vocabulary fosters learning for the development of a conceptual understanding of multiplication and as a basis for developing derived-fact strategies. For a deeper insight and a comparison between different children's development see Götze (under review).

### **The individual learning trajectory of Ilay**

Ilay (I) worked together with his normal-achieving classmate Nelli (N) during the fostering course. Ilay is a very communicative child who likes to contribute to class discussions and really likes to explain how he arrived at his solution. This is less the case with Nelli.

During the first support unit Ilay knew many multiplication tasks from the times tables off by heart. Otherwise he used the strategy of repeated addition or count-by sequences. While doing so he usually started to recite the times tables from one, something which was very time consuming. For instance, he needed a total of 45 seconds until he could provide the correct solution to the problem  $6 \times 7$ . While reciting, he raised individual fingers one after another sometimes even two at once, which would indicate additive calculation. He explained how he arrived at the solution as follows.

- 56 Ilay: Because when you now, when you now... aahmmm... then that's 7 (points to his thumb) plus 7 (points to his index finger) are then 14. And then you work out these 2 (points to his middle finger and his ring finger) are also 14. There are 28 in total. And then you only need to add this 14 (holds up the next two fingers). In total around 42.
- 57 Teacher: And what comes out at the end of this problem? (points to the task  $7 \times 7$ )
- 58 Ilay: Around... 48 (he starts to count his fingers forward once again, whispers) 14, 28, 42. So... (after 25 seconds) 49.

Ilay worked out the result by availing of additive references (turn 56 and 58). For him it appeared that being asked to multiply was more a request to count up. In doing this, Ilay displayed typical one-sided additive ideas with respect to multiplication and little strategic knowledge (Gaidoschik et al., 2018). Furthermore, he was not able to derive the solution for the new task  $7 \times 7$  from the previous task  $6 \times 7$ .

In order to emphasise the differentiation of multipliers and multiplicands for Ilay, during the second support unit the meaning-related vocabulary for the same groupings was introduced (step 2). In the following scene, approximately ten different rectangular arrays were laid out in front of the children, which also included the correct array for the task  $3 \times 5$  (for Ilay and Nelli a task from the fifth row).

- 7 Teacher: I will now give you the problem. Do you know the game, “I spy with my little eye”? We will now play using the cards: I spy with my little eye lots of 3 groups of 5 each (places the note “3 groups of 5 each” in front of the children).
- 8 Nelli: 3 groups of 5 each?
- 9 Teacher: Do you have any idea which dot image I mean?
- 10 Ilay: (points uncertainly at the card containing the dot image relating to  $3 \times 5$ )
- 11 Teacher: Why could that match?
- 12 Ilay: Yes, because here are 5 (points to the uppermost row)
- 13 Nelli: ... because there are 5 in each row.
- 14 Ilay: ... because there are 5 in each row, so...
- 15 Nelli: ... 15.
- 16 Ilay: So when you now calculate (takes the card with the rectangular array  $3 \times 5$ ), 1, 2, 3 (tips each of the respective first dots of the first column), there are 3 below and here, calculate 1, 2, 3, 4, 5 (tips each of the respective dots of the first line), then these are 15 and here are 3 groups of 5 each (points to the note with the same sentence).
- 17 Teacher: Okay, so where are the 3 groups of 5 each?
- 18 Ilay: 3?
- 19 Teacher: You have already said that these are 3 and 5. But where are the groups of 5?
- 20 Nelli: Here at the top (moves along the top line).
- 21 Ilay: Exactly, and we then have a group of 5 here (moves along the top row), two groups of 5 together, three groups of 5 together (moves along the other rows).

It can be seen that the children initially react in an uncertain manner to this unknown vocabulary (turn 8, turn 10). Even when Ilay directly found the requested dot image (turn 10), he was still not able to immediately explain why the description “three groups of five” matched this dot image. He pointed to the first column and the first row (turn 12, turn 16). This focus can be seen in many low-achieving children and indicates a limited conceptual understanding (Moser Opitz, 2013). Nelli, on the other hand, seemed to understand the content immediately, which can often be seen in the case of normal-achieving children (Götze, 2018). She emphasised that in each row there must be five dots (turn 13), which Ilay then repeated word-for-word (turn 14). Thus, Ilay had not yet understood the content of this formulation because he could not answer the follow-up question of the teacher (turn 17, turn 18). The teacher correctly recognised that although Ilay pointed to the numbers three and five of the term in the rectangular array in his customary manner, he had not yet started to think of cardinal groups of always five dots. It was only when Nelli pointed out the group of five in the dot image to him that Ilay rethought (turn 21) and recognised this new perspective.

The overall evaluation of the data from the support units of all ten low-achieving fostered children demonstrated that this scene appeared to be a key scene in the learning process for low-achieving

children such as İlay. If they were to understand the grouping concept, they had to be given a new way of looking at the rectangular arrays by means of the new language being offered. In order to ensure that the children did in fact understand the content of the subject matter, substantial repetition was needed in order for the children to make this new way of looking at rectangular arrays a part of their own mental models.

In this respect, in the third support unit İlay showed that he began to integrate the meaning-related vocabulary into his own mental thought patterns (step 3). It was astounding that already in the third support unit he seemed to give up on his additive viewpoint that he had so strongly been focussed upon up to that point. He explained why the term  $6 \times 6$  matched to the corresponding rectangular array without having to be asked to do so by the teacher.

- 123 İlay: So, I took this one here because that is 6, so 6 is here (moves along the left column with his finger) and there are 6 groups (moves his finger from left to right several times) ... And here 1, 2, 3, 4, 5, 6 (taps on each of the respective points in the first row), there are 6 in a group, and when you count down (moves the finger from top to bottom), then 1, 2, 3, 4, 5, 6 (taps on each of the respective points in the first points), that's actually really easy.

First, he addressed the groups number, in other words the multiplier, by pointing to the six groups in the right corner ("there are 6 groups"). Subsequently, he described the meaning of the second six in the term ("there are 6 in a group"). Drawing on the meaning-related vocabulary he had learnt, he completely independently explained the differentiation of both sixes in the term  $6 \times 6$ : one indicates the number of groups, the other the group size.

In order to obtain first indications about a possible further development of derived-fact strategies, in the fourth support unit, the children were supposed to try to make deductions between the tasks. In the following scene, İlay was asked to think about why  $7 \times 5$  is always seven more than  $7 \times 6$ .

- 47 İlay: Because, that (points to the multiplier) stays the same and that (points to the multiplicand), that should, if you jump over one, then that should now also be 7s.
- 48 Teacher: I don't quite understand that. What do you mean, if you jump over one?
- 49 İlay: If you count one to here (points to the multiplicands 5 and 6), then that will, then it is, if you, a 7, if you (points to both multiplicands) count up to 7.
- 50 Teacher: So, if we have 7 times 5 and 7 times 6. Why is it 7 more?
- 51 İlay: Nelli, you count it.
- 52 Teacher: That's right. But I am not convinced yet. 5s become 6s.
- 53 İlay: Oh! Because here, here, you have 6. And then one always comes in here, (points to both multiplicands), it only comes, if we do that with the dots, it only comes, so one, so one, so one row, so one dot always becomes more.

At the beginning of the scene, İlay initially tried to explain the correlations with his own linguistic means and using lots of pointing gestures (turn 47). Indeed, he also occasionally used meaning-related vocabulary such as "sevens" but could not yet use it to explain the content-related correlation of  $7 \times 5$  and  $7 \times 6$ . Only the direct reference of the teacher in turn 52 ("fives turn into sixes") seemed to activate the meaning-related vocabulary for him. He was then able to use it to explain the multiplicative (not

additive!) correlations very independently (turn 53). In contrast to the first support unit, he did not use his finger to count the rows but thought purely in terms of content. This content-related thinking in multiplicative structures was shown several times in the fourth support unit.

It can be seen in the above analysis that İlay completed the intended four learning steps. After the introduction of the basic meaning related vocabulary, he first needed some time for practice and networking with concrete representations (step 2), before this vocabulary slowly became İlay's own vocabulary of multiplicative thinking (Pöhler & Prediger, 2015; step 3). Perhaps this newly formed content related multiplicative thinking provided the basis for using derived-fact strategies. Repeated addition was a dead end for him in multiplicative understanding. With this respect, the meaning related vocabulary fulfilled a cognitive and epistemic function for him. Expressions such as “3 times 5” were no longer a “secret language”, and the multiplication in rectangular arrays was really perceived in a multiplicative way via these expressions.

## Discussion and limitation

İlay's learning trajectory stands representative for other fruitful learning trajectories of other children. All these learning trajectories have in common that the children start to *think in groups of the same size*. The fostered vocabulary seems to support the development of a mental model in all these children. The meaning-related verbalizations become the language of thinking and therefore, the children can understand how to decompose or derive multiplication tasks. This multiplicative point of view has apparently not been obvious to the children in their previous learning biography through formal expressions such as “3 times 4” or “3 multiplied with 4” or “4 multiplied by 3”. However, basic meaning-related phrases such as “3 groups always with 4 (dots) in a group” or “3 groups of 4” illustrate thinking in multiplied groups of equal sizes. This vocabulary then fulfils *epistemic functions* in the learning process and contributes to conceptual understanding. The problem with this is repeatedly having to detach low-achieving children from using their old, supposedly safer strategy of repeated addition. Throughout, the children use both additive and multiplicative ideas at the same time. The in-depth analysis of children such as İlay therefore shows how central it is to continue to promote this new multiplicative point of view. Furthermore, the in-depth analysis demonstrates that the multiplicative thinking seems to be a good basis for the development of decomposition strategies. If children can think in a content-related way they can also derive tasks from each other and recognise correlations between tasks.

Despite that, not all supported children show these learning developments (for details see Götze, under review). The most striking factor however is that these children do not start to think multiplicatively. The meaning-related vocabulary does not become the vocabulary of thinking for these children. This is mostly caused by the teacher who starts to retrieve facts and vocabulary (for example “Where are the groups in this term? Where are the number of groups in the rectangular array?”) instead of supporting multiplicative thinking. Especially in this paper only one single-case study can be presented. For a comparative analysis it would be helpful to contrast İlay's individual learning trajectory with those of other children (see Götze, submitted). But that would go far beyond the scope of this paper.

This study is laid out as qualitative Didactical Design Research (Pöhler & Prediger, 2015). First of all, the aim was to derive hypotheses about the effectiveness of the support and not to operationalize them. Therefore, the duration of the fostering was very short, with just four support units. Yet, the study provides first indications that the conceptual understanding of multiplication can be promoted in a language sensitive manner when we can achieve that the children use the meaning-related vocabulary as their vocabulary of thinking. How long the fostering should actually last for the supported children to be able to independently think in a content-related way, remains unanswered. Future research must therefore check the hypotheses made in this paper.

# Claims and demonstrations of understanding in whole class interactions

Jenni Ingram and Nick Andrews

University of Oxford, Department of Education, England; [Jenni.Ingram@education.ox.ac.uk](mailto:Jenni.Ingram@education.ox.ac.uk)

*One aim of teaching mathematics is to develop students' understanding of mathematics. In this paper we examine how teachers and students do understanding in interaction, and how this understanding is handled interactively during whole class interactions. Taking a Conversation Analytic approach, we look at interactions between teachers and students where there is claim of understanding and where there is a demonstration of understanding. We show how these two situations are handled differently, by the teacher and the students, with only the latter situation being concerned with students' understanding.*

*Keywords: Conversation Analysis, classroom interaction, understanding.*

## Introduction

One aim of mathematics teaching is to both develop students' understanding of key ideas, concepts and methods, and to respond to difficulties students encounter in understanding mathematics. Studying understanding in mathematics education is not original, but the existing research largely treats understanding as something real, as something that students do or do not have. However, understanding is also used by teachers and students in interaction for practical purposes, and this use or display of understanding is observable and analysable. The aim of the analysis in this paper is to investigate what the uses of words like 'understand', 'sense' or 'mean' do in interaction, focusing on how teachers and students are using these words to achieve different things. We use Sack's notions of claiming and demonstrating understanding as is observable in the interaction, rather than making any claims as to whether students actually understand or not, which is not directly observable in interaction.

Pedagogic interactions, and in particular teacher-student classroom interactions, are dominated by the IRE interactional structure. The IRE (or IRF) sequence, teacher initiation-student response-teacher evaluation, has been written about extensively (e.g. Hellermann, 2003; Mehan, 1979; Sinclair & Coulthard, 1975; Wells, 1993). This characterisation, however, only focuses on the broad structure of the interaction, rather than the multiple activities being done within it. The third turn, the evaluation turn, in particular does more than evaluate a student's answer as correct or not, but also comments on its adequacy as a response to the initiation, and its appropriateness for the broader interactional and pedagogical purposes of the interaction (Macbeth, 2003), and influences the interaction that follows. What is being assessed or evaluated by the teacher in this third turn is not necessarily focused on the content of the student's response, but could also, or alternatively, focus on how the response enables the interaction to progress, they are task-oriented rather than content-oriented (Antaki, Houtkoop-Steenstra, & Rapley, 2000). Koole (2012) also showed that teacher assessments in this third turn can focus on students' knowing, students' doing or students' understanding. However, positive assessments largely focused on students' knowing, treating their

response as shared knowledge on which to build on, but negative assessments largely focused on students' doing or understanding.

In this paper we focus on IRE sequences where the content focus includes understanding, or not understanding. In particular, we examine instances where evidence of understanding (or not understanding) is displayed by teachers or students in whole class interactions. These instances can include situations where the teacher-initiation requests students to claim or demonstrate understanding, which might include teachers themselves claiming or demonstrating understanding or not understanding, or situations where it is the students who make claims or demonstrations of understanding relevant in their response turn, or finally situations where the teacher's evaluation turn treats the student's turn as a claim or demonstration of understanding. Our analysis of these sequences takes a Conversation Analytic approach drawing upon Sacks' discussions of 'how understanding is shown' (1992:II:140). We make use of Sacks' distinction between *claiming* and *demonstrating* understanding and show that the teachers in these interactions treat claims and demonstrations differently, being content-oriented when there are demonstrations of understanding but task-oriented when there are solely claims of understanding.

## Methodology

This analysis was carried out on a video corpus collected in fifteen mathematics teachers' classrooms in ten schools in England of secondary educations (students aged 11-18). All names used are pseudonyms. These videos were transcribed using Jefferson transcription (Jefferson, 1984) and the analysis focused on these transcripts, but they are presented here in a simplified form for ease of reading. The transcripts of all whole class interactions in a total of 39 lessons were analysed using Conversation Analysis (CA) (Sidnell & Stivers, 2012). The CA approach was used to develop a collection of cases (Sidnell, 2010) examining how the topics of understanding and sense-making are treated by the teachers and students as they interact. These cases include 299 interactions where the teacher explicitly talks about understanding and 58 where a student explicitly talks about understanding (including interactions about making sense, getting it, and finding meaning). In this paper we focus on those interactions that broadly follow the IRE structure in that they involve both the teacher and the students, rather than those that occur during a teacher explanation for example.

From a CA perspective understanding does not refer to a cognitive state but to an interactional object where teachers and students do understanding as they interact. For example a student saying 'I don't know' is often used to request help from the teacher, or to initiate a complaint about an explanation (Lindwall & Lymer, 2011). As such, we are not making any claims about what teachers or students understand, instead focusing on how they use understanding in interaction to achieve particular things. Within CA research a distinction is made between demonstrating and claiming understanding (Sacks, 1992). For example, a teacher can *demonstrate* understanding of what a student has said by responding with an alternative formulation as in the following extract:

- |    |          |                                                                           |
|----|----------|---------------------------------------------------------------------------|
| 25 | Teacher: | ... what is the difference then, what makes a histogram a histogram. Jin? |
| 26 | Student: | because the bars can be wider                                             |
| 27 | Teacher: | exactly in a histogram, you can have different width um bars...           |

### Extract 1: Tom's lesson on statistical diagrams

Alternatively, the teacher or student could just respond ‘yes’ or ‘good’ which would merely *claim* understanding.

In classrooms teachers generally ask questions that they already know the answer to, and as such student responses are demonstrations that they also know the answer. However, students can respond in a way that shows *that* they have understood, or in a way that shows *what* they have understood (Koole, 2010). Whilst showing *that* they have understood can involve either a claim or a demonstration of understanding, showing *what* they have understood requires a demonstration of understanding. Koole (2010) also showed that teacher questions of the form “do you understand” are usually followed by a *claim* of understanding and not a *demonstration* of understanding.

## Results

In the data we present here we will demonstrate that *claims* of understanding support the smooth progression of interaction (Stivers & Robinson, 2006) that is underpinned by shared understanding (Weatherall & Keevallik, 2016). That is, *claims* of understanding are affiliative joint accomplishments that enable the interaction, and the lesson, to continue, but tell us nothing about what students understand. On the other hand, *demonstrations* of understanding tell us something about what students do or do not understand, but also lead to more extended interactions that focus on the content of these demonstrations, rather than moving the interaction on.

### Claims of Understanding

Claims of understanding usually follow an understanding check by the teacher, such as “do you understand?” or “does that make sense”.

- 70 Teacher: is (.) does that make sense?  
 71 Students: yeah  
 72 Teacher: okay Simone did you do it exactly the same. (.) no slightly different. thank you Steve. er Simone could you (.) explain what you did. was it-

#### Extract 2: Becca’s lesson on multiplying fractions

Here the students have made a *claim* of understanding in their answer yeah in turn 71, but there is no evidence of what they understand or the nature of their understanding within the interaction. The teacher acknowledges this claim in turn 72 before moving on to a different student and asking them to explain their method.

Another situation where there is a *claim* of understanding but without a *demonstration* of understanding is given in extract 3.

- 173 Teacher: numbers pick one of the numbers as a value for n. work out the missing numbers, using the same shape, apply that rule to somewhere else, see if you can add them up to be um using this rule like this one if I draw that C anywhere else I should find that I get er five n add two will tell me, if I draw a C in here, er draw this c in one two three four five. five times thirty-two is a hundred and sixty, add two makes a hundred and sixty-two. SNAME  
 174 Student: I don’t understand

175 Teacher: okay I'll come and see you. it will be seven minutes, to have a go, starting now.

### Extract 3: Ryan's lesson on a hundred square investigation

In turn 173 Ryan is describing how to draw a letter C on a hundred square and then sum the numbers in the letter C by treating one of the squares as  $n$ . In turn 174 a student makes a *claim* of not understanding but does not add anything that would indicate what they do not understand, so no *demonstration* of understanding or not understanding. This claim is requesting help from the teacher. Ryan acknowledges this request but defers dealing with the issue before continuing to talk to the rest of the class.

These teacher turns that include understanding checks are not always followed by student responses as in extract 4:

178 Teacher: ...but if I drew another rectangle and had that as two and four, that isn't similar to that cus they're not in the same proportions, yeah? does that kind of make sense? It's a bit of a weird mathematical word. right? but we have to get used to it in a mathematical thing, so it doesn't quite but congruent certainly is going to come up. okay. so we're going to start with reflections, but...

### Extract 4: Imogen's lesson on transformations

Here Imogen asks "does that kind of make sense?" but without pausing and without any students responding continues here turn before moving on to a new topic at the end of the extract.

Where there is a *claim* of understanding (or not understanding) but no demonstration of understanding, the interaction continues without any reference to what has, or has not, been understood. Where the teacher has invited a claim of understanding but no student response is given, again the interaction continues without any reference to what has, or has not, been understood. Since 'do you understand' or 'does that make sense?' questions prefer a *claim* of understanding rather than a *demonstration* of understanding (Koole, 2010), when no response is given it is a *claim* of understanding that is 'noticeably absent' (Bilmes, 1988) and in every case in this data where there is no response, the interaction continues in the same way as if there had been a positive *claim* of understanding. In contrast, as we will show in the next section, when there is a *demonstration* of understanding, or not understanding, the following interaction focuses on the content of the understanding and extends the IRE sequence (Schegloff, 2007).

### Demonstrations of Understanding

Teachers can explicitly ask students a question that requires them to *demonstrate* their understanding. In extract 5, Fiona asks the student to explain so that she and the other students can understand, and the student gives an explanation in turn 188. In the turn that follows Fiona focuses on one part of the student's explanation and asks a follow up question.

187 Teacher: right explain it to me so that I understand but also so that people that haven't done this one understand 'cause I know that there's quite a few people who haven't done it

- 188 Student: is it because Rio is forty degrees and I've worked out that Khartoum is thirty-five degrees you just add five
- 189 Teacher: right where did you get thirty-five from for Khartoum, was that one of the ones that we've worked out

#### **Extract 5: Fiona's lesson on negative numbers**

In extract 6, Tom is asking why it makes sense to take a moving average over four points when dealing with quarterly sales of ice cream. The student, Sayed, gives an explanation which Tom then follows with a prompt to be more specific in turn 70, to which the student responds with more detail.

- 68 Teacher: yeah it is because of that so why, why does that make sense, can you say so why does that makes sense to use four in the numbers. it is something to do with the fact that it's quarterly. Sayed?
- 69 Sayed: because there's four quarters
- 70 Teacher: where
- 71 Sayed: in the end, in a year
- 72 Teacher: yeah there's four quarters in a year but, so, you know so ...

#### **Extract 6: Tom's lesson on moving averages**

One of the most common ways that teachers ask about students' understanding is in relation to the meaning of mathematical vocabulary.

- 11 Teacher: ah that's a good word isn't it isosceles. what do you understand by isosceles
- 12 Student: erm two lines that are perpendicular they're straight lines and then they have two of the same angles
- 13 Teacher: we're getting lots of different mathematical words aren't we. um two lines are perpendicular what do you mean perpendicular.

#### **Extract 7: Dave's revision lesson**

In turn 10, before the transcript begins, a student has given a justification for an angle having a particular value as being because the triangle is isosceles. Dave follows this up in turn 11 by asking this student what he understands by isosceles, which he explains in turn 12, (inappropriately) introducing the word perpendicular to describe the two sides with equal length. Dave then follows up on this and returns the turn to the student to explain what he means by perpendicular.

In these three extracts the teacher's initiation includes an explicit request for a *demonstration* of understanding, which the student gives in their response, and which is followed by the teacher asking a follow-up question focused on the content of the students' demonstration which returns the turn to the student. Demonstrations of understanding can also occur when a student is indicating that they do not understand something. In extract 8, a student has given the equation of a straight line using the gradient and the y-intercept which Dave repeats in turn 71. Dave then opens up the floor to invite questions from the students at which point a student asks how to find the equation and states that he does not understand. This is both a *claim* of not understanding and a *demonstration* of what it is that

is not understood<sup>1</sup>. The teacher follows this with an explanation for how the class found the equations of straight lines in previous lessons as well as giving a rule.

- 71 Teacher: ...yes three x plus one. um okay that's fine. who wants to ask anything about the first side, you do. go on
- 72 Student: um how do you find out the um equation I don't understand it
- 73 Teacher: no okay. this three I remember we went to the computer room and drew some things didn't we this three turned out to be the gradient and this one turned out to be where it goes through the y axis. so once you've found out the gradient is three you can just stick it in there um that requires quite a bit of thought doesn't it um at this stage with the exams coming up just stick it in there in front of the x and you put plus one on the end because of that and it all fits in with the pattern we saw when we drew lots and lots and lots of these in the computer room ...

### Extract 8: Dave's revision lesson

Furthermore, whilst the student in turn 72 treats the issue as one of understanding, the teacher's following turn treats it as an issue of remembering (Koole, 2012).

In each of these cases where there is a demonstration of understanding, or not understanding, the teacher's follow up turn focuses on the content of the students' responses. This is in contrast to the situations where there was only a *claim* of understanding where the teacher's follow up turn moved the interaction on. This arises both in situations where the teacher has asked students about their understanding as well as where students indicate that they do not understand. However, this second situation is rare in whole class interactions. Also, where the teacher has requested the demonstration of understanding in their initiation, the teacher's third turn also returns the turn to the same student. The preference for moving the interaction on following *claims* of understanding is reinforced by the numerous occasions where teachers ask "do you understand" but does not wait for an answer before moving on to the next topic (as illustrated in extract 4), which occurred in just over 40% of cases of understanding checks in this data (in contrast to Koole (2010) where the students always responded).

## Conclusion

In this paper we have focused on how *claims* and *demonstrations* of understanding are dealt with by teachers and students in their interactions. Within the IRE structure, teachers can invite either *claims* of understanding or *demonstrations* of understanding in their initiation, and this distinction is further supported by the students who in their responses give either a *claim* or a *demonstration* as required by the teacher's initiation. However, teachers and students are doing different things when they invite or give *claims* to when they invite or give *demonstrations*. Claims of understanding are treated as ways of supporting the progressivity of the interaction (Stivers & Robinson, 2006) and do not deal with the content or issues of what is or is not understood. In contrast, *demonstrations* of

---

<sup>1</sup> Whilst the student utterance of "how do you find out the um equation" could be interpreted as an issue of knowledge or knowing, the student treats it as an issue of understanding by following it with "I don't understand it" rather than "I don't know".

understanding lead to the interaction focusing on the content of these demonstrations and an expansion of the IRE structure.

### Transcript Notation (Jefferson, 1984)

[ text ]	Brackets	Indicates the start and end points of overlapping speech.
(.)	Micropause	A brief pause, usually less than 0.2 seconds.
.	Period	Indicates falling pitch or intonation.
?	Question Mark	Indicates rising pitch or intonation.

# Talking about standardized units in preschool – supporting language and mathematical learning

Sarah Keuch and Birgit Brandt

Technical University Chemnitz, Germany; Sarah.Keuch@zlb.tu-chemnitz.de

*Today, the important role of language use for successful (early) mathematical learning processes is widely accepted and researched. Starting from the preschool teacher as an influencing variable for language learning and the mathematical content of measuring, this paper reconstructs opportunities for supporting conceptual as well as language learning in small group interactions planned for mathematical learning in preschool. The way preschool teachers talk about units ranges between a linguistically rich ‘language bath’ and an action-oriented ‘activity bath’ and thus offers different learning opportunities.*

**Keywords:** Early mathematics education, measuring, linguistic competence, oral language.

## Introduction

Despite the fact that large-scale studies have shown the impact language has on mathematical learning processes, the German school system is still in need of concepts to support children with disadvantageous starting conditions, for example migration background, low socio-economic background or developmental speech disorders. These children are still not provided with equal chances to take part in (mathematical) educational processes (Gogolin & Lange, 2011). Ensuing from these observations, for example, Prediger (2015) claims that academic language education processes should start as early as possible. While most research on language-sensitive teaching in Germany focusses on primary or secondary schools (Gogolin & Lange, 2011; Leisen, 2015), fostering academic language in preschool could contribute to improving educational injustices. Further, academic language education processes should be designed age-appropriately and oriented towards a specific content. Prediger and Zindel (2017) ask for more topic specific research in order to specify the concrete linguistic demands for mathematical contexts. Studies show that preschool teachers possess only insufficient knowledge concerning basic linguistic terminology, language acquisition and effective interventions (Michel, Ofner, & Thoma, 2014). These results are especially alarming if one takes into account that even preschool children who speak only one language are still language learners (Volmert, 2005). Hence, there is not only a lack of concrete concepts for integrated mathematical and language learning, but also for professionalizing preschool teachers in order to be able to implement such concepts. With the analysis of language usage in interactions during mathematical activities, we try to address this gap.

Our overall aim is to raise preschool teachers’ language awareness and practical knowledge for fostering academic language proficiency (Isler, Künzli, & Wiesner, 2014) and mathematical learning. In a first step, we specify this aim by looking at the use of language in kindergarten interactions concerning magnitudes. On a linguistic as well as mathematical level, units are a crucial part of measuring. Since we found measuring of children’s body length and the accompanying measured values as a recurring theme, we take a deeper look at the verbalization of units and indications of size.

After elaborating on linear measuring, the topic of our content-specific research, we present the empirical data, some results and a preliminary discussion.

## Linear measuring in preschool

Measuring is not only one of Bishop's (1988) six basic mathematical activities, but is also seen as a basis for the development of mathematics as a science in all cultures and many curricula for early mathematics education in Germany put emphasis on measuring. Further, it represents a link between mathematically abstract concepts and everyday life, and comprises multiple inner-mathematical relations, especially with numbers and geometry. Beyond, the concept of measuring can be seen as a basis for further concepts, for example fractions and rational numbers (Barrett et al., 2011). While we take research on children's acquisition of a (geometric) concept of magnitudes, milestones and difficulties (Sarama, Clements, Barrett, van Dine, & McDonel, 2011) as a background for our linguistic analysis, we will not discuss it in detail. Although an integrated approach for different spatial magnitudes, especially in early education, is seen as reasonable in order to understand the differences and the fundamental idea of measuring as comparison with a unit (Barrett et al., 2011), here we only concentrate our linguistic analysis on length. Length and area are more easily perceivable and accessible for young children than other magnitudes, although they might be difficult to distinguish (Skoumpourdi, 2015). The activity of measuring length concentrates on the determination of a linear expansion. Therefore, you have to distinguish between objects with a rather clear linear characteristic, for example sticks or distances, and those objects with more than one dimension that can be measured (width, height, depth) (Nührenbörger, 2002; Skoumpourdi, 2015). Consequently, it becomes obvious that speaking about length comes along with specific linguistic challenges, for example concerning the characteristic of linearity and the differentiation from area. In order to obtain a profound concept of measuring, children need to understand the act of *iteration*. In order to obtain a measure, a subdivision of a certain length is translated. Each of these subdivisions has to be equal, the concept of *identical unit*. With these identical units, you fill out a certain space, the so-called *tiling*. In order to fill out a space completely, it might be necessary to *partition* units. Lastly, measures can be added so that a measure of eight units can be thought of as a composition of five and three suggests the concept of *additivity* (Lehrer, Jaslow, & Curtis, 2003). While some research suggests starting with non-standardized units and only introducing units like centimeter and meter later in the process, this rarely meets the children's reality. Based on this theoretical background, we focus on the following research questions:

- Which linguistic resources are at preschool teachers' disposal when talking about standard linear units?
- How are the acquisition of (academic) language and mathematical application supported in these interactions?

In order to answer the research questions, we follow methods from interactional linguistics (Couper-Kuhlen & Selting, 2000). Interactional linguistics takes an interdisciplinary and cross-linguistic perspective on language. It looks at the structure and use of language, capturing it in its natural environment, the social interaction. Based on the linguistic element used in the utterance, we look at their role in the conversation. In our context, these linguistic elements are utterances containing

standardized units to describe or accompany measuring processes. We are interested in situations in which units are used in ways which might lead to meanings within the child's and the kindergarten teacher's mind. Apart from that, we are interested in structures that deviate from a normatively correct way and which might therefore inhibit the construction of measuring concepts or at least make it harder for children to understand the concept of length. If applicable, the central concepts in linear measuring that might be transmitted through the preschool teachers' utterances are pointed out. These questions are part of a larger project which also looks at the language used with other magnitudes, older children at primary school and syntactical, lexical and semantic aspects, because "developing measurement sense can be conceptualized as learning the language of measurement, with attention paid to the semantics, syntax, grammar and pragmatics of measurement" (Joram, 2003, p. 65).

## Empirical data and results

The data basis for our analysis consists of videotaped mathematical situations designed by preschool teachers from the project erStMaL (early Steps in Mathematical Learning) (Acar Bayraktar, Hümmer, Huth, & Münz, 2011). From this data basis, seventeen situations are concerned with magnitude and measuring, which are the corpus of our project (for detailed information on these situations see Brandt and Keuch (2017)). These small group interactions with one preschool teacher and two to five children were transcribed and annotated using the transcription and annotation tool EXMARALDA (Schmidt, 2002). Ten of these seventeen situations deal with the magnitude length. In order to be included into the following analysis, the utterance has to include some kind of standardized linear unit. In a first step, we differentiated between units that accompany numbers (indication of size) or that appear on their own. Indications of size are further analyzed according to which units are used and how they are combined with the respective number(s). The following utterance by one of our preschool teachers serves as an illustration for the different types of using units in indications of size:

Sabine: You are one meter and nineteen centimeters. Look, that's what the number looks like. One hundred nineteen centimeters are one meter nineteen.

For the first indication of size in her utterance, Sabine uses a number (one), then the unit (meter), the conjunction 'and', then another number (nineteen) and another unit (centimeter). So this part of her utterance is annotated as 'x m and y cm'. In the second part of her utterance she uses centimeters only, so this would be coded as 'x cm', and then she uses a shortened, colloquial form without 'and' and without 'centimeters'. This would count as 'x m y'. Preschool teachers use units more than four times more often than children (see Table 1) do. Moreover, only three children produced utterances containing units. In most cases, preschool teachers use units within indications of size. Teachers talk four times more often about centimeters than about meters. If they use mixed forms, they tend to use a shortened, colloquial version. In contrast, children never use mixed forms (but they use numbers without units to indicate size, which are not included in this analysis). Preschool teachers use units without numbers to list the different units that exist in different countries, but without giving further explanations as in the following example: "You can measure in meter or in centimeter and in America I think you measure with inch. We measure here with meter and centimeter". The following table shows how numbers and units are combined within indications of size and how often each variation is used in all ten situations dealing with length:

	<i>Units total</i>	<i>without numbers</i>	<i>x cm</i>	<i>x m</i>	<i>x m and y cm</i>	<i>x m y</i>	<i>x inch</i>
<i>Preschool Teacher</i>	88	13	41	10	4	19	1
<i>Children</i>	19	5	11	3	0	0	0
<i>Total</i>	107	19	52	13	4	19	1

**Table 1: Use of units in all ten situations dealing with length**

After this global view on the general usage of units, we now look at explanations that preschool teachers give for the meaning of units. Only two of them, Berna and Sabine<sup>1</sup>, try to explain what a unit (in their cases centimeter) is, hence we concentrate our following analysis on them.

Sabine: Every number is a centimeter. That means such a small piece is a centimeter. You see that also on the ruler, don't you?

Berna: From one long line to the next, so just this little box yes? That's a ... that's a centimeter there.

In the first part of her utterance, Sabine compares the numbers on the folding stick with centimeters, the numbers equal the centimeters. With this explanation, she might want to address the concept of identical units. Barrett, Jones, Thornton, and Dickson (2003) warn that focusing on the numbers or marks on a measuring device might impede seeing length as an aggregation of segments or units. Berna, however, hints at the distance between two-centimeter marks on a tape measure, which she calls 'little box'. This expression can be (mis-)interpreted as a two-dimensional square (for example on graph paper) or as a three-dimensional object. In any case, defining linear units by using two- or three-dimensional objects like 'piece' or 'little box' might lead to confusions with area measuring (Keuch & Brandt, 2018). Starting from the former defined centimeter, Sabine tries to explain the need for other units like meter and hint to the concept of partitioning: "But when we now uhm calculate everything in centimeters, then the numbers must be much too big". Sabine hints to the inverse relationship between the number of units and the size of the unit (Grant & Kline, 2003). However, she never explains what exactly a meter is (or its relationship with centimeters), but puts a folding rule on the floor, folded in a way that it is one meter long, claims that 'that' is a meter and goes on with the next activity: "Look! And that's a meeeter! Do you now want to know how tall you are?"

Berna explains the relationship between meter and centimeter (partition) in two steps. First, she elaborates on ten centimeters and finally she draws the link to one meter, hinting at the decadal structure. However, the children's job in the second step is simply to read out the number hundred:

Berna: That's a meter. And in one meter, from the beginning to the end are? Which number is this?

Friedel: Mhm hundred.

---

<sup>1</sup> The children in these two situations are 6;0 – 6;2 (Berna) and 4;11 – 5;11 (Sabine) years old.

Berna: Hundred centimeters. So that means that in such a meter are hundred ... little boxes.

Berna tries to initiate a number of tasks that hint at the idea of iteration, identical units and tiling while referring to different measuring devices: “So, from the beginning to the seven are how many centimeters then Can?”<sup>2</sup> When she notices the children’s difficulties, she refers back to her explanation of *little boxes* and rather focuses on counting discrete little boxes (although there are no clear visible boxes on the folding stick) instead of continuous units:

Berna: One little box is always one centimeter and now count the little boxes up to seven.

Berna: Look, it is ... the numbers don’t play any role now. From one to the other mark, only one little box, is always one centimeter. Yes?

With this statement, she indirectly hints to the concept of identical units and also to the fact that every point on a measuring device can be used as a zero point. No such utterances that contain the idea of identical units, iteration or tiling were found in any other situation. Moreover, one has to consider that the children in the interaction with Berna are the oldest children in the corpus of our project. Sabine as well as Berna hint to the concept of additivity. While Sabine, in an indirect way, puts emphasis on the difference between the heights of two children, Berna takes two measuring results and adds them up in order to get a result, which equals one of the children’s height.

Sabine: And you are one meter twelve tall (...) one centimeter bigger than Theresa!

Berna: So we have now twenty-five and hundred centimeters. So, one meter are hundred centimeter, plus the twenty-five to that. Then now I can tell you that Can is one meter and twenty-five centimeters long.

Interestingly, Berna first transfers one meter into hundred centimeters and then adds more centimeters. Her result however is a mixed indication of size consisting of meter and centimeter. Sabine seems to immerse the children in a kind of ‘language bath’ to offer them a linguistically rich environment and she might hint to the concept of partitioning and additivity. In this situation, units accompany the measuring process. She never asks the children questions about units but rather integrates them as ‘silent’ participants into the measuring process. When measuring the children’s body length, Sabine uses units in various ways to express their size, also using adjectives or reading out the single digits to make those numbers that exceed the children’s actively mastered number range more comprehensible:

Sabine: Oh you’ve got a funny number. You are one meter eleven tall. Look! One meter eleven is a one, a one and another one.

Berna makes the children participate mentally and physically by posing different questions or asking the children to show her a centimeter with their fingers on a measuring device but also limits her talk on units to these devices. When she determines the children’s body length, mainly non-standardized units like building blocks are used, except when she calculates Can’s body length. However, she asks

---

<sup>2</sup> In German (“So, vom Anfang bis zu der sieben sind wie viele Zentimeter dann, Can?”) the utterance is not completely grammatical and the author tried to stay as close as possible to the original.

many questions concerning units so that the children get a chance to test and apply their mathematical and language knowledge:

Berna: From one long to the other long mark it's a...?

Friedel: Meter!

Berna: Noo one centimeter, but you were really close. Well done Friedel!

While we were able to show that Berna tends to correct lexical mistakes very often and very directly (Brandt & Keuch, 2018), she seems to have a quite relaxed attitude towards the difference between meter and centimeter. While from a linguistic perspective, there really is just one prefix that differentiates the two words, mathematically there are ninety-nine centimeters in between.

## Conclusion

In this paper, we looked at the use of standard units in small group interactions in preschool. It became obvious that preschool teachers used units more often than children did. The children rarely spoke about units. This might have to do with limited elicitations by the preschool teachers. They, on the contrary, used units and indications of size in various ways, with the latter most often expressed in mixed and incomplete structures. When the context is clear, leaving out units in everyday settings would not inhibit the understanding, but it contradicts the idea of fostering academic language. Focusing on Berna and Sabine, both preschool teachers seem to possess pedagogical as well as didactical knowledge. Yet, we could only observe limited language awareness regarding the introduction of standard units. Central concepts of linear measuring like iteration, identical units, tiling, partition, and additivity are addressed rarely and mostly indirectly. In both situations, it is not clear which (if any) conceptual understanding of units and scale values the children develop beyond the actual context. The negotiation process related to the mathematical content stayed at the surface especially for linguistically less competent children since some explanations might not have been accessible for them and therefore they did not get a chance to improve their mathematical and (active) linguistic competences. Berna almost completely restricted units to the scales of measuring devices. Nevertheless, the children might have gotten a better idea of the actual size of a centimeter (although it might interfere with area) because of her multiple questions and tasks. It remains unclear how far the children were able to transfer their knowledge to the actual measuring activities in the situation and beyond. Because of Sabine's lack of questions and tasks concerning units, the actual concept and size might have stayed unclear. Following her rich 'language bath' concerning body sizes, the children in this situation might get a feel for expressing indications of size, even beyond this situation. This 'language bath' was integrated in the cultural practice of measuring with standard units. Through this subjective-bodily involvement, she might enable more indirect learning which can leave marks and offer connectivity options for later (direct) mathematical and language learning opportunities.

## Mathematical reasoning as a classroom discourse

Farran Mackay, Marieke Thurlings, Alexander Schueler-Meyer, and Birgit Pepin

Eindhoven University of Technology, Eindhoven School of Education, Eindhoven, The Netherlands; [f.e.mackay@tue.nl](mailto:f.e.mackay@tue.nl), [m.c.g.thurlings@tue.nl](mailto:m.c.g.thurlings@tue.nl), [a.k.schuelermeyer@tue.nl](mailto:a.k.schuelermeyer@tue.nl), [b.e.u.pepin@tue.nl](mailto:b.e.u.pepin@tue.nl)

*Keywords: Mathematical reasoning, mathematical discourse, classroom practice.*

### Introduction

Mathematical reasoning is recognised as an essential means for promoting students' mathematical understanding and is central to students' mathematical proficiency (e.g., Kilpatrick, Swafford, & Findell, 2001). However, the teaching and learning of mathematical reasoning – here understood as a discursive practice – remains challenging in secondary school classrooms, with students often relying on mathematically superficial reasoning (e.g., Sidenvall, Lithner, & Jäder, 2015). Teachers need to have at their disposal effective discursive teaching practices to foster students in developing their ways of mathematical reasoning. This raises the question of how teachers can be supported in developing such discursive teaching practices with respect to mathematical reasoning. This question is addressed in the PhD-project of the first author. The intention of this poster is to elicit feedback concerning the inferences made from the analysis of mathematical reasoning teaching practices, within a discursive framework.

### Theoretical framework

Sfard (2008) argues that 'doing mathematics' is a *discourse*, that is, the use of specific, well-defined communication. As such, mathematical reasoning can be considered as the line of thought, both the inter- and intrapersonal discourse, that is utilised to produce statements and reach conclusions while solving a task. Mathematical discourses are framed as a type of communication that is distinct to others through the permissible "vocabularies, visual mediators, routines and endorsed narratives" (Sfard, 2008, p. 297). *Routines* are a set of rules defining a discursive pattern that repeats itself in certain situations. For example, the use of the quadratic formula is a routine. *Endorsed narratives* are an ordered sequence of expressions which are labeled as *true*. They describe mathematical objects (e.g. numbers, functions, and formulae), relationships between objects, and the processes through which the objects are constructed. Examples of narratives endorsed by the mathematical community (e.g., mathematicians and teachers) include definitions, axioms, and theorems as well as acceptable forms of presenting solutions to specific tasks (e.g., answer models within state exams).

The completion of a mathematical (school) task can be considered as the production of an endorsable narrative from existing narratives (Sfard, 2008). The activity of choosing which previously endorsed narratives are relevant to the task at hand and how these narratives are to be manipulated to create a new (endorsable) narrative is fundamentally what mathematical reasoning is. In this process, students need to adhere to well-defined rules within the mathematics community. Fostering mathematical reasoning thus requires the teacher to explain the rules and mechanisms of endorsing narratives in classroom conversations. Such a meta-discourse about rules and mechanisms can be considered as a

mathematical discourse in itself because it has its own vocabulary, visual mediators, routines and endorsed narratives. This discourse is coined *mathematical reasoning discourse*.

## Methodology

As part of a larger project, the present study is conceived to examine the mathematical reasoning discourse that teachers employ in their classrooms. At the time of CERME11, the present study was in the data collection phase. The results of this exploratory study will be used as one of the inputs, in the following study, for the design and evaluation of a professional development module in relation to advancing teachers' mathematical reasoning discourse.

The exploratory study consists of ten lesson (video) observations and stimulated recall interviews with five Dutch mathematics teachers at the upper secondary level. The interviews consist of non-evaluative questions asked while watching pre-selected video-scenes of their classroom routines. The questions are designed to stimulate the participant to relive the lesson, and, through this, to reflect on his/her routines (Geiger, Muir, & Lamb, 2016), to identify the conditions influencing their choice of routines and the types of routines they employed (Cooper & McIntyre, 1996), and what they deem as a successful implementation of their routines (cf. closing conditions of routines, Sfard, 2008).

The planned approach to the data analysis is the following:

1. Video sightings for identifying teacher routines in the mathematical reasoning discourse (also used as stimulated recall)
2. Qualitative discourse analysis of the (video) observations to examine the discursive means (narratives, keywords, visual mediators) for fostering the students reasoning
3. Qualitative discourse analysis of the stimulated recall interviews to uncover teachers' intentions behind their routines and as such meta-rules for mathematical reasoning discourse

From the design of the exploratory study, the expected output would include (successful/promising) routines that teachers use, and the associated meta-rules in relation to mathematical reasoning discourse. However, this raises the following question for discussion in the context of TWG09: how can inferences be made from the here presented exploratory study to a broader teacher community in order to inform the design of the professional development module?

# Researching translanguaging: Functions of first and second languages in Maltese mathematics classrooms

Angel Mizzi

University of Duisburg-Essen, Faculty of Mathematics, Essen, Germany; [angel.mizzi@uni-due.de](mailto:angel.mizzi@uni-due.de)

*This paper presents a research study about the different functions of languages in teachers' translanguaging practices at primary level in the Maltese islands. Translanguaging denotes learning environments which support individuals to activate different languages in the learning or teaching process for facilitating interaction between individuals for constructing and communicating knowledge cross-linguistically. Bilingual primary teachers, Maltese and English-speaking, were accompanied during the introduction of mathematical concepts in order to identify the different functions of both languages in their discourse when teaching mathematical concepts.*

*Keywords: Language, multilingualism, translanguaging, primary mathematics education.*

## Introduction

Language plays an important role in mathematics learning, not only to communicate mathematical knowledge to each other, but also to construct mathematical knowledge cognitively (Maier & Schweiger, 1999). Several studies highlighted the importance of integrating content and language learning in mathematics learning environments, wherein, along with the content itself, language development is also a learning goal (Wessel, 2015; Farrugia, 2017). Other studies about multilingualism in learning environments state how important it is to consider the students' first language in contexts where the second language is the language of education (Cummins, 1981). However, more research is needed to investigate the different functions which two languages have in multilingual mathematics classrooms, especially when teachers use both languages to teach mathematical concepts bilingually.

The ongoing research project focuses on how two languages, which are both used by teachers and students in Maltese mathematics classrooms, influence mathematics teaching and learning at primary level. The use of both languages by teachers will be observed during the introduction of mathematical concepts in order to achieve insights into the functions of both languages. The main research question is: What are the functions of two languages used by bilingual primary teachers when translanguaging in their mathematics teaching?

## Theoretical background

A quite common notion in linguistics research about multilingualism is the concept of codeswitching. Codeswitching denotes the process of switching from one language to another at discourse level for a more effective communication between bilingual speakers. In contrast to codeswitching, translanguaging denotes teaching methodologies which incorporate the use of one language for supporting the development of the second language for facilitating student understanding (Lewis, Jones & Baker, 2012). Lewis et al. (2012) emphasize that the use of two languages is cognitively high-demanding for students and this process should not be merely considered as translation:

The process of translanguaging uses various cognitive processing skills in listening and reading, the assimilation and accommodation of information, choosing and selecting from brain storage to communicate in speaking and writing. Thus, translanguaging requires a deeper understanding than just translating as it moves from finding parallel words to processing and relaying meaning and understanding. (Lewis et al., 2012, p. 644)

Similarly, Baker describes translanguaging as "the process of making meaning, shaping experiences, understandings and knowledge through the use of two languages" (Baker, 2011, p. 288). According to Baker (2001) advantages of using translanguaging includes a deeper understanding of the content and support of the weaker language in the learning process. Hence, translanguaging focuses on the cognitive processes during learning and does not only emphasize the external mode of communication when switching from one language to another (as in the case of codeswitching). Nevertheless, codeswitching is a prerequisite in order to get insights into the cognitive processes in translanguaging teaching and learning environments.

The use of two languages for teaching and learning of mathematics leads to multidimensional symbolic representations of mathematical knowledge in the context of translanguaging, as it has been illustrated by a model about the different representations of mathematical knowledge under consideration of multilingualism by Prediger and Wessel (2011). This model emphasizes that different registers can be realized using different languages, e.g., first language on the level of everyday language and second language for mathematical language.

### **Research design, methods and implementation**

In order to qualitatively research the functions of two languages when teaching mathematical concepts, a case study with different teachers was designed. It was important to find a scenario where teachers and students speak both languages, where both languages have roughly the same status in the society, and where translanguaging is the norm in the educational context. Due to these prerequisites the case study was conducted in Malta, where both Maltese and English are used for teaching and learning at primary and secondary level. Maltese primary teachers are allowed to use both languages for teaching mathematics and in order to support mathematical learning independently from the language chosen in the classroom, as stated in the Maltese primary mathematics curriculum:

The class teacher, in accordance with the school strategy, is to decide what language must be used to facilitate the development and acquisition of mathematical concepts. Once, this objective is achieved, however, it is essential that children are exposed to the mathematical ideas in English (...) However, on no account should the use of either language (Maltese or English) impede upon the children's learning of mathematics. (Department of Curriculum Malta, 2014, p. 10)

The research study was conducted in a fourth and sixth grade at a primary school in Gozo, an island in the Maltese archipelago. Two teachers were observed during the introduction of several mathematical concepts. The fourth-grade teacher introduced the concepts of fractions and their equivalency and weight and mass in two different lesson units. The sixth-grade teacher introduced the concept of percentages. Nearly all students in the observed classes have Maltese, a Semitic language and first language for the majority of the Maltese population, as their first language, and English, the language of the former colonizers, as the second language. Both languages are taught at

school starting from first grade in primary schools. The same language conditions apply for the participating teachers, who additionally studied educational studies in English at university in Malta.

The lessons of the teachers in the units were audio-recorded and observed in the classroom in order to note the different materials (e.g., books, smartboard, hands-on, etc...) used by the teachers when introducing the mathematical concepts. The recordings were transcribed and analyzed qualitatively in order to investigate the use of translanguaging, in particular, the different functions both languages fulfill during the teaching of mathematical concepts.

## Results

Preliminary analyses of the recorded data show that teachers use translanguaging intensively when introducing mathematical concepts in both classrooms and that language choice also tends to depend on materials used (e.g., hands-on). Three main functions of the first and second language during the introduction of the concepts were identified and are described in the upcoming subsections.

### First language as oral and second language for the fixation of the mathematical language

A particular remarkable observation is the different functions of the two languages regarding oral and written modes. The first language, Maltese, was used by both teachers only orally, whilst the written form of mathematics was only realized using English. Maltese was often used for communicating mathematical phenomena orally, and English was used to capture the mathematical insights written, as it can be observed in Transcript 1 (T stands for teacher and S for student):

#### Transcript 1

	Original in Maltese and English	Translation
T1	(...) ħa naraw bejn wieħed u ieħor kemm jiżnu l-affarijiet. Aħna rajna li <b>one packet of flour</b> , li tfigħer dqiq, f-l-o-u-r jiżen <b>one kilogram</b> . (...) Biex nkunu kapaċi nagħmlu <b>estimate</b> . Inqabblu bejn il-ħaġa li tiżen iktar jew inqas minn <b>pakkett dqiq</b> . Iktar jew inqas minn <b>one kilogram</b> ? Rajna li <b>around five oranges weigh one kilogram</b> . Għadkom tiftakru kemm jiżen <b>baby tat-twelid</b> ?	(...) we are going to see how much things weigh approximately. We saw that <b>one packet of flour</b> , which means flour, f-l-o-u-r weighs <b>one kilogram</b> . (...) So that are able to <b>estimate</b> . Comparing whether one thing weighs more or less than the packet of flour. More or less than <b>one kilogram</b> ? We saw that <b>around five oranges weigh one kilogram</b> . Do you remember how much a newborn baby weighs?
Choir	Three or four.	Three or four.

*1 packet of flour = 1 kg.*

*Around 5 oranges weigh 1 kg.*

*A newborn baby weighs around 3 1/2 kg.*

**Figure 1: Whiteboard inscriptions accompanying Transcript 1**

The scene in Transcript 1 originates from the introduction of weight and mass in grade 4, after the students (S) had learnt how to read the weight using different scales. This transcript shows an extract from the introduction to comparison and estimate of objects' weight. In this scene the first or second language is not merely used for translation purposes. The lesson goal is formulated by the 4<sup>th</sup>-grade teacher (T1) in Maltese but summarized using the concept estimate in English. The knowledge about objects, especially their weight, e.g. “around five oranges weigh one kilogram”, is formulated and written down in English (see Figure 1). English is the textbook language in Maltese mathematics classes, and this is reflected in the choice of writing mathematical phenomena in English. In contrast, Maltese is used for the oral description of the mathematical phenomena, especially the action of comparing the weight of objects. In other instances, Maltese is used for activating learnt knowledge, e.g. “Rajna li...” (We saw that...) or “Għadkom tiftakru...” (Do you remember...) in Transcript 1.

### **First language for concrete experiences and second language for the abstraction of mathematical phenomena**

The use of two languages in mathematics classrooms was noticed during the teaching of mathematical phenomena which are first based on concrete representations and becoming more abstract in further learning processes. The first language seems to be more used for activating everyday knowledge, and the second language is used for abstracting the underlying processes, as it can be observed in Transcript 2, in which the 4<sup>th</sup>-grade teacher (T1) introduces equivalent fractions using hands-on:

#### Transcript 2

T1	Illum, we have twenty-four small squares, (...) if I want to eat one fourth of the chocolate, if one, two, three, four (pointing to four students) are going to share the chocolate, ha naqsmu ċ-chocolate bejn one, two, three, four, (...) kemm se tiehdu kull wiehed?	Today we have twenty-four small squares, (...) if I want to eat one fourth of the chocolate, if one, two, three, four (pointing to four students) are going to share the chocolate, we are going to break down the chocolate among one, two, three, four, (...) how much will each get?
S1	Two?	Two?
T1	Two? (pointing at the squares of the bar) One two, one two, one two, u one two, jibqa' din il-biċċa. (...)	Two? (pointing at the squares of the bar) One two, one two, one two, and one two, this piece remains. (...)
S2	Six.	Six.
T1	Nistgħu npinguha u naqsmuha f'erbgħa. One, naqsmu waħda minn nofs, u waħda minn nofs hawn (uses gestures to show how to break the bar into half and then each into halves). (...)	We can draw it and break it down into four. One, we break down one in half, and one in half here (uses gestures to show how to break the bar into half and then each into halves). (...)
S3	Teacher, jew taqsam hekk. One, two, three... (points along the rows)	Teacher, or we break it like this. One, two, three... (points along the rows)

T1	That's another method, very good. (...) K'naqsmuha f'erbgħa, one, two, three, four, dawk ir-rows, kull wieħed kemm jieħu? Ghoddu!	That's another method, very good. (...) If we break it down in four, one, two, three, four, these rows, how many does each get? Count!
Choir	Six. (...)	Six. (...)
T1	What fraction? (...) How many pieces? Six. (...) What fraction?	What fraction? (...) How many pieces? Six. (...) What fraction?
S4	Six from four. (...)	Six from four. (...)
T1	Six on? Out of how many?	Six on? Out of how many?
S4	Four.	Four.
T1	Ara, are there only four in all? How many in all?	Look, are there only four in all? How many in all?
S4	Six times four.	Six times four.
T1	Six out of twenty-four. (...) Kieku naqsmu ċ-ċikkulata hekk, u kull wieħed se jieħu one fourth, kemm hemm squares?	Six out of twenty-four. (...) If we break down the chocolate like this, and each gets one fourth, how many squares are there?
Choir	Six.	Six.
T1	Six. Mela, what is another fraction? What can I say instead of six on twenty-four? (...)	Six. So, what is another fraction? What can I say instead of six on twenty-four? (...)
S2	One fourth.	One fourth.
T1	(...) So what can you tell me about these two fractions? Six on twenty-four and one fourth. What can you tell me about them? Jekk jiena rrid niekol ħafna ċikkulata, liema nagħżel din jew din (shows on the two fractions)?	(...) So what can you tell me about these two fractions? Six on twenty-four and one fourth. What can you tell me about them? If I want to eat a lot of chocolate, which one do I choose, this or this? (shows on the two fractions)?

In Transcript 2, the 4<sup>th</sup>-grade teacher activates the concept image of distributing parts of a whole using a (six times four) chocolate bar to be shared among the students. The teacher states the number of subgroups (four students), the fraction, and poses the question, “How many pieces per child?”. Although more English is used in the teacher's discourse, both languages are used to fulfill different functions at concrete and abstract level. Although the lesson goal is stated in both Maltese and English separately, the focus is on the act of sharing or breaking down the chocolate and on how much each child shall receive, which is often emphasized in Maltese by the teacher: “ħa naqsmu ċ-chocolate” (We are going to break down the chocolate) and “Kemm se jieħu kull wieħed?” (How much does each get?). English is used to denote the fraction, “one fourth of the chocolate”, and to represent the

underlying information. The more the transcript progresses, the more Maltese is used to denote the action of breaking down or sharing, whereby at a certain point even the Maltese numbers accompany this action, in “K'naqsumha f'erbgħa” (if we break it down into four), in order to denote the break down number. However, the parts broken down into are named using English numbers, the ordinal aspect of natural numbers. The English numbers are also used to describe the denominator and numerator of the intended fraction, and at the end of Transcript 2, the teacher uses mainly English to encourage the students to compare both fractions (see Figure 2), however, at a certain point, she uses Maltese again for activating student everyday knowledge (the act of eating chocolate) at the end of Transcript 2. Overall this episode shows that whereas the first language, Maltese, was more used in contextual situations of mathematics learning, English became more dominant when representing abstract mathematical objects, which were introduced concretely.

$$\frac{6}{24} \quad \frac{1}{4}$$

**Figure 2: Whiteboard inscriptions accompanying Transcript 2**

### **First language for action-based processes and second language for static concepts in mathematics classroom**

The third distinction regarding the functions of the first and second language in translanguaging in mathematics lessons is between the static and dynamic processes of mathematical knowledge. Analyses of the previous transcripts led to the hypothesis that Maltese tends to be used more for action-based processes, e.g. comparing weights in Transcript 1 or breaking down objects in Transcript 2, whereas English is more used for representing static concepts, e.g. estimate, square, numbers, etc. The next transcript from Grade 6 shows how the first language is primarily used for dynamic process, whereas the second language is used more for static contexts of mathematics knowledge.

#### Transcript 3

T2	(...) ġo dan is-sejf għandna sixty euro w l-mami tgħidlek: ara, tista' tonfoq ten percent minnhom kull xahar. U kif se nsir naf jien kemm nista' nonfoq? Ten percent xi tfisser? (...)	(...) in this safe we have sixty euro and mum tells you: look, you can spend ten percent of it monthly. And how can I find out how much I can spend? What does ten percent mean? (...)

Choir	Times ten.	Times ten.
T2	‘l fejn se jaqbeż il-point?	Where will the point jump to?
Choir	‘l hemm. (pointing to their right)	There. (pointing to their right)

In the above transcript, Transcript 3, the 6<sup>th</sup>-grade teacher introduces the exercise 10% of 60 Euros in percentages using the everyday register. In order to solve “ten out of sixty”, the students start using division, sixty division by hundred, however the underlying processes in the division exercise are perceived and hence also verbalized using the first language. Such processes include the identification of the decimal point, how many steps and in which direction the decimal point must be moved and whether the number value increases or decreases. Similar to Transcript 2, numbers (in contextual situations) associated with actions or movements, such as moving the decimal point, are represented using the first language, e.g. “Għax ħa jiċkien. Wiehed. Tnejn” (Because it will decrease. One. Two) in Transcript 3. English is more used for static insights on mathematical concepts, for concept names, e.g., Division or Multiplication (“times” in Transcript 3) or for number names (e.g., ordinal aspect).

## Conclusion

The above transcript and their analyses in the results section show how two languages can have different functions in translingual mathematical classrooms and they are not merely used for translation purposes. The teachers participating in this study used one language for oral explanations and communication of mathematical phenomena and the second language for ‘fixiating’ the mathematical language and learnt knowledge. Findings showed how the first language is more used for verbalizing concrete representations of mathematical knowledge, since it is dominant in the students' everyday life. For instance, actions on objects are more likely to be communicated using the first language. The second language is required to abstract the mathematical phenomena, especially when the context is no longer in focus; For example, during the introduction of equivalent fractions in Transcript 2 the teacher tended to use Maltese for expressing actions on hands-on, whilst English was used for denoting the fractions and their comparison. Further findings showed that the first language was more used when mathematical actions were verbalized, whilst the second language was

high used for static mathematical concepts. Hence, languages can fulfill different functions in a translingual mathematics classroom in order to enhance language and content learning. Similar to the thesis that the development of the mathematical language requires the use of everyday language as a basis (Wessel, 2015), the use of the first language (especially in the introductory phase) is crucial in order to develop, learn and use the abstract mathematical language in multilingual classrooms.

### Acknowledgment

I wish to thank the dedicated teachers participating in this study, the head mistress and Dr. Marie Therese Farrugia from University of Malta for the fruitful discussions about translanguaging.

*This study examines the use of languages by bilingual undergraduate mathematics learners. It adopts a commognitive lens to examine whether language use by bilingual undergraduate mathematics learners impacts upon meta-level mathematical processes of learners, in particular in relation to functions. The findings suggest that there was a lack of code switching between languages when engaged in mathematical tasks and completing the mathematical tasks individually or in pairs impacted on the choice of language employed in the discourse. There was greater evidence of meta-level thinking through the medium of Irish than in English.*

**Keywords:** *Commognitive approach, language use, functions, bilingual students.*

## Introduction

An evaluation of the Irish and English languages demonstrates that differences exist in relation to syntax and semantics and that this may impact on the processing of mathematical text, and advantage those learning through the medium of Irish (Ní Ríordáin, 2013). Specifically, this paper examines two first year undergraduate students' (approx. age 18 years) thinking about functions and which language(s) (Irish and English) are used to facilitate their thinking. These students were participating in a bilingual first year Calculus module. In particular, we focus on concepts relating to functions, which are fundamental to mathematics learning across all levels of education, inclusive of university-level education (Gücler, 2016). We adapt Sfard's (2008) commognitive framework as an analytical lens to support our investigation of bilingual mathematics learners. This framework is adopted for a number of reasons including: to enable an examination of participants' discourses relating to functions; to facilitate a comparison of object-level and meta-level developments of functions in both English and Irish languages; and accordingly, to examine when participants are utilising their languages when engaged in mathematical thinking.

Therefore, considering object-level and meta-level level thinking and requirements in relation to functions, this research aims to make a contribution to the field by examining how languages (Irish and English) are utilised by bilingual undergraduate learners when engaged with functions discourse. Utilising Sfard's (2008) commognitive perspective, mathematical thinking is viewed as a form of communication, and that learning mathematics entails extending one's discourse from object-level to meta-level constructs. Adopting this perspective on thinking and considering that discourse is language dependent, the authors contend that discourses may differ between languages (Kim, Ferrini-Mundy & Sfard, 2012). In particular, the authors propose that there are variances between different linguistic forms of "the same discourse" (Kim et al., 2012, p.2) and accordingly it may impact on how bilingual students utilise their language(s) when engaged in mathematical thinking.

Planas and Setati (2009) argue that bilinguals switching between their languages is not just dependent on their proficiency in the languages but also due to the social situations and contexts. It is important that we study bilingual learners and their diverse contexts in order to gain a better understanding of the complexity of the issue and the influence of language(s) on mathematical thinking. It is well established that the ‘choice’ and use of language(s) may differ depending on the context (e.g., Planas & Setati, 2009). Research suggests that the type of mathematical tasks students encounter as well as the situated learning experiences facilitated, can influence language use and code switching (Moschkovich, 2007). Moschkovich asserts that some students may opt to use their first language when working on a task individually and code switch as necessary when engaged in interactive discourse concerning the same mathematical problem. Alternatively, if students associated mathematics with a particular language, it is reasonable that the students would then communicate their thinking in that language, i.e. their second language. Another alternative is that students might opt to code switch throughout the mathematical discursive processes. For example, Planas and Setati (2009) established differences in the ways that immigrant bilinguals utilised their languages whilst completing mathematical tasks. Switching between languages (Catalan and Spanish) occurred with changes in the complexity of the mathematical tasks required by the teacher. In general, they found that the students used their languages for different purposes and was dependent on the social context set up within the classroom (*ibid*). Ultimately, research suggests that that primary influencers of how students use their languages for learning mathematics are (1) the mathematical discursive competencies in a given language, (2) the social context, and (3) relative experience of mathematics (Moschkovich, 2007).

## Theoretical frame

Gee’s (1996) concept of discourse as encompassing, verbal, written, technical and physical modes of language use informed the close analysis of mathematical discourse in this study. The authors were cognizant of the social aspect of language use in learning and required a framework that allowed for the examination of discourse as a complex form of communicating while paying close attention to the cognitive processes of mathematical thinking. Therefore, the authors adopt Sfard’s (2008) commognitive approach to analysing mathematical discourse in order to provide for the particular methodological considerations and central constructs of the study (mathematics discourse, bilingualism and language use). Sfard expresses thinking as comprising both personal and interpersonal communication and outlines four unique features of mathematical discourse, which this study explores as a process of socialisation into a mathematical community of practice. These discourse tenets are: 1) words use, 2) visual mediators, 3) routines, and 3) endorsed narratives. For the purpose of this paper the authors focus on word use and routines.

Word use is characterised by Sfard (2008) in terms of *passive-driven* (recognition or memorisation), *routine-driven* (using phrases or definitions), *phrase-driven* (task association) and *object-driven* (meaning-making) usage. Objectification is a feature of word use in mathematical discourse, which occurs through a process of reification (structural thinking) and alienation (impersonal presentation of phenomena). Therefore, this research was interested in whether participants engaged in objectified talk and in which language(s) this occurred. To this end, word use was categorised as above and considered in line with the routines feature of mathematics discourse. Sfard categorises routines as

*deeds* (a change in the environment), *rituals* (cooperative acts of learning) and *explorations* (producing an endorsed narrative). Of particular significance to this study was the course of action employed by learners to solve mathematical problems (deeds) and the mathematical reasoning provided (explorations). A particular emphasis was placed on the language(s) in which each routine was discussed or employed. The practice of learners alternating between their languages is referred to as code switching in this paper.

The authors align with Gee's (1996) concept of discourse as a sense-making process, comprising modes of communication and participation in communities of practice. Comprised of both talk and non-talk forms of communication, Gee (1996) describes discourse as 'stretches of language that "hang together"' and are embedded in the situated and sociocultural practices of its use' (p.115). Further, the authors define meta-level developments in mathematical thinking as a process of endorsing the rules that govern the particular mathematics discourse, while object-level mathematical thinking refers to familiarisation with the objects of the discourse (Sfard, 2008). In terms of mathematics as discourse, the authors view mathematics as a complex register comprising subject content conveyed through the interchangeable use of everyday (colloquial) and mathematical (literate) discourses. As such, developing an advanced mathematics discourse culminates in a shift from a colloquial to a literate use of mathematical language, which signifies conceptual (meta-level) knowledge.

## Methodology

At the National University of Ireland, Galway (NUI Galway), first year undergraduate mathematics students are afforded the opportunity to study honours mathematics through a bilingual approach. Modules offered bilingually are Calculus and Algebra. Four weekly lectures are provided through the medium of Irish, with all mathematics terminology offered bilingually (Irish and English). In addition, lecturers may opt to describe more complex concepts (such as the limit of a function) bilingually. The lectures are supplemented by the provision of a weekly tutorial in English in addition to an Irish-medium tutorial. Participants were comprised of two students, Val and Jean. Two Irish-medium education contexts exist – Irish-immersion education in English-speaking communities and schools located in Gaeltacht (Irish-speaking) regions. Val was from a Gaeltacht region and attended primary and secondary schools in that region, and therefore Irish was his dominant language. Jean attended immersion primary and secondary education, with English her dominant language. Accordingly, both Val and Jean learned Mathematics through Irish but in different contexts in terms of the dominance of the English and Irish languages. At university, the dominant language of informal communication for both participants was English.

The study adopted a mixed methods approach to data collection. This study identified the plausible mathematical discourse trajectories in relation to functions for both the English and Irish languages. The purpose of these discourse trajectories is to examine object-level and meta-level developments in the both languages, and consequently identify which language(s) are used and how, as related to functions (Kim et al., 2012). Participants also completed a questionnaire. The purpose of the first part of the questionnaire was to gather participants' background data. The second part of the questionnaire engaged participants in functions discourse through the use of mathematical questions appertaining

to graphing and limits of functions. All questions were presented bilingually, providing participants with the option of utilising English or Irish or both languages. Jean and Val were invited to think-aloud their thought processes as they recalled prior knowledge and experiences of mathematical discourses while answering the questions (Desimone & Carlson Le Floch, 2004). Finally, cognitive interview methods were employed in which both students were provided with the same mathematical problems as they had solved individually in the questionnaire (one week later). Students were invited to discuss their understandings, processes and thinking about how they approached the various questions and to negotiate their respective thinking towards substantiating the narrative of the particular mathematical constructs in question (functions). This method was employed to acquire comprehensive knowledge about what students' discursive patterns revealed about their comprehension of the specific mathematics functions concepts central to the study (Desimone & Carlson Le Floch, 2004).

Qualitative data analysis included a synthesis of thematic, framework, video and discourse analysis procedures. Sfard's (2008) Commognitive Framework for analysing mathematics discourse was employed to analyse students' meta-level mathematical thinking and related language use. The data was coded, recording both data-driven and concept-driven codes (Gibbs, 2007). Concept driven codes were the discourse tenets: word use, visual mediators; routines and endorsed narratives (Sfard, 2008). Meta-level discursive statements and linguistic patterns were gathered at this stage. Cross coding was employed to code a piece of data for more than one code. Three rounds of coding allowed for similar codes to be grouped and re-characterised and redundant codes were set aside. Parent and Child themes (Gibbs, 2007) were employed to further categorise the data and all codes, categories and themes were considered in terms of English, Irish or both languages, as well as object or meta –level learning.

## Findings

A learning example is provided in Figure 1 which details students' mathematical problem solving routines and their language use. Both the individual explanations and the paired discussions are provided. Val and Jean mostly utilised Irish in the individual interview and English in the paired interview. In the example provided, the students' answers are provided in the language in which they spoke/wrote, with English translations provided for those instances where Irish was utilised.

**Questions:** (i) What is the natural domain of a function  $f(x) = x^2$ ? (ii) Explain to your friend how the domain for  $f$  must change if the inverse of  $f$  is to exist. (iii) Explain what the inverse function  $f^{-1}$  is when  $f(x) = x^2$  (with suitable domain).

### Val's Individual Answer:

**Original text:** Anseo  $f(x)$ , tá sé os cionn, mar síos anseo [pointing to the third quadrant] tá uimhreacha diúltacha ar fad, so abair lúide a haon, lúide a dó. Mar  $x$  cearnaithe [ $x^2$ ] níl ann ach dá uimhir, [pauses] an uimhir  $x$  fá [meadaithe fá] é féin, so lúide a haon fá lúide a haon sin a haon. So chuile dá uimhir diúltach beith siad, em deimhneach. So, caithfidh gach páirt a bheith anseo [pointing to the region within the u-shape line drawn on the graph]. So sin é an graif. Maidir leis an inbhéarta ní, níor, like, ní cuimhin liom é a dhéanamh. Tá a fhios agam go ndearna muid é ach ní cuimhin liom and ábhar sin sa rang.

**English translation:** Here  $f(x)$ , it is above [the  $x$  axis], because down here [pointing to the third and fourth quadrants] the numbers are all negative. So let's say minus one, minus two. Because  $x^2$ , it is just a number [pauses], it is the number  $x$  multiplied by itself, so minus one multiplied by minus one is one [ $-1 \times -1 = 1$ ]. So every second negative number would be positive. So, every part has to be here [pointing to the region within the u-shape line drawn on the graph]. So that's the graph. With regards to the inverse, I don't remember how to do it. I know we did it but I don't remember that topic from class.

### Jean's Individual Answer:

**Original text:** So an céad piosa ann, tá an fearann na réaduimhreacha go léir mar níl aon, níl aon fadhb leis. Mar shampla an ceann eile [referring to the previous question] bhí roinnt ar naid. Agus anseo, an inbhéarta, caithfidh an fearann a bheith  $x$  níos mó ná, nó cothrom le naid, mar nuair a déanainn tú amach an inbhéarta, an chaoi a déanann mise é, 'swapáil' mé an  $x$  is an  $y$  agus cuireann mé  $x$  ar  $y$ , like, leis féin. So faigheann tú préamh  $x$ , agus chun préamh  $x$  a ríomh, caithfidh  $x$  a bheith deimhneach, nó naid.

**English translation:** So for the first part, the domain is all the real numbers because there is no problem with it. For example, the other one [referring to Q1] it was to divide by zero. And here, the inverse, the domain must be  $x$  more than or equal to zero, because when you do the inverse, how I do it is, I swap the  $x$  and the  $y$  and I put  $x$  on  $y$ , like, on it's own. So you get the root of  $x$ . And to calculate the root of  $x$ ,  $x$  has to be positive or zero. [does not complete (iii)]

$f(x) = x^2$   
 fearann:  $\mathbb{R}$   
 $f^{-1}(x) = \sqrt{x}$   
 $y = f(x) = f^{-1}(y)$   
 Caithfidh  $x$  a bheith  $\geq 0$   
 fearann:  $x \geq 0$

### Paired answer (original text was in English):

1. **Val:** [reads Q.2] Can that be  $\mathbb{Z}$ ?
2. **Jean:** Which one is  $\mathbb{Z}$  again?
3. **Val:**  $\mathbb{R}$ , isn't  $\mathbb{R}$  like from 1 up and  $\mathbb{Z}$  is like all the negative numbers and all the positive numbers?
4. **Jean:** Isn't  $\mathbb{N}$ ,  $\mathbb{N}$  from 1 up, I think? I'm not sure, I was never really any good at this.
5. **Val:** And then, yeah, yeah, and  $\mathbb{R}$  then is  $\mathbb{N}$  and  $\mathbb{Z}$ , isn't it?
6. **Jean:** Is it? OK.
7. **Val:** That makes more sense, I think so. [reads Q.2 part (ii)].
8. **Jean:** I don't remember what I did here [in relation to Q.2(ii)]. [Writes the answer on answer sheet]
9. Oh yeah [shows her answer sheet to Val]. See like, the way in secondary school how I learned to get the inverse was change the  $x$  and the  $y$
10. around, like say the original one is like that [writes  $y = x^2$ ]. And then put  $y$  instead of  $x$  and instead of  $y$ , and then get  $y$  on it's own to get 11. like, the inverse [circles  $x$  on answer sheet].
12. **Val:** Oh yeah, OK, OK. [Reads part (iii) and says:] I don't have a clue for that one.
13. **Jean:** Yeah, to be honest I didn't know either.

Val's written answer:

$\mathbb{R}$

Jean's written answer

$\mathbb{R}$   
 $y = x^2$   
 $x = \sqrt{y}$

Figure 1: Learning example

### Word use

In his explanation Val utilises Irish and employs a combination of deictic language with colloquial and some literate discourse. Deictic language, such as 'os cionn' (above), 'anseo' (here) and 'síos anseo' (down here) (in reference to the Cartesian plane), is combined with gestures (pointing to the associated quadrants on the graph) to highlight where the domain on the Cartesian plane is for function  $f(x) = x^2$ . There are elements of routine-driven words being employed since Val is describing the graph. There is little evidence of flexibility in Val's word use and objectified talk about the global features of the graph is not evidenced. In general, Val does not address the domain in this question and the mathematical explanation remains at an object-level of understanding. In contrast,

Jean uses routine-driven mathematical words such as ‘fearann’ (domain), ‘réaduimhreacha’ (real numbers), ‘inbhéarta’ (inverse), and the phrase ‘níos mó ná, nó cothrom le’ (more than or equal to), which signifies familiarity with the subject content and related procedures and ease of use of the mathematical discourse in the Irish language. However, even when utilising Irish, Jean does not fully explain what  $R$  is or why in fact there is no problem with it in this instance, indicating that word use here is routine-driven and procedural. In their discussion of this same mathematics questions, Val opens this interaction in English and despite both students utilising Irish in their respective individual interviews, neither Val nor Jean negotiate their preferred language use for mathematics learning (which is Irish, as indicated in the questionnaire). When both students discuss in English the natural domain of function  $f(x) = x^2$ , they employ passive-driven words such as ‘positive numbers’ and ‘negative numbers’, and expressions such as ‘from 1 up’. Their word use in English does not progress from passive-driven towards more object-driven usage as it tended to when the students utilised Irish.

### Routines

In Figure 1, explaining the natural domain of a function  $f(x) = x^2$ , Jean explores the inverse of a function in the individual interview by first explaining (in Irish) that the domain must be  $x$  more than or equal to zero in order for the inverse of  $f$  to exist. Jean then clarifies that this reasoning is related to the routine of “doing” the inverse: ‘an chaoi a déanann mise é, ‘swapáil’ mé an  $x$  is an  $y$  agus cuireann mé  $x$  ar  $y$ , like, leis féin. So faigheann tú préamh  $x$ , agus chun préamh  $x$  a ríomh, caithfidh  $x$  a bheith deimhneach, nó naid.’ (I swap the  $x$  and the  $y$  and I put  $x$  on  $y$ , like, on it’s own. So you get the root of  $x$ . And to get the root of  $x$ ,  $x$  has to be positive or zero). There is an attempt at reification with the use of the word ‘inbhearta’ (inverse) as a verb. However, overall Jean’s rituals (routines utilised for social rewards) define the repetitive discursive action or metarules for “doing the inverse” but there is little evidence of routine flexibility or explanations of why these rituals constitute an appropriate series of steps (meta-level thinking). Instead, there is a focus on pre-learned associations and repetitive patterns or routines (the domain of the function is  $R$  but does not explain what  $R$  is) and rote practices (learning how to swap the  $x$  and  $y$ ).

### Discussion and conclusion

There was a lack of language negotiation and code switching engaged in by both students throughout the learning process. Therefore, as Planas and Setati suggest (2009) the social situations and context of the learning scenario play a role in how the learner utilise their language for engaging in mathematics discourse. Both students employed Irish mostly when engaged individually in mathematics discourse but employed English when communicating with one another about the same mathematics topic. This is similar to Moschkovich (2007) who affirms that some students may opt to use their first language when working on a task individually. However, code switching was not evident in our study, even though the same mathematical problem was utilised in both the individual and paired tasks. Since there were two students only undertaking the bilingual stream of this undergraduate program, the whole group discussion was limited and group work was not facilitated. Hence, there were very few opportunities for social interactions within the learning context and as a result the opportunities for language choice and negotiations were also limited. Within the lectures, students conformed to the classroom linguistic norm of speaking Irish and carried this through to

individual interviews. However, the language of paired communication was English, which is the dominant language within the Irish third level education setting. This study has found that the choice of language used by bilingual undergraduate students in this context was influenced by their views of language use in given situations (Caldas & Caron-Caldas, 2002). The impact of the social context is a key consideration for future studies relating to bilingual undergraduate mathematics learners.

Overall the learners demonstrated a combined use of colloquial and literate words and tended towards more colloquial word use when communicating together and through English. There are perceptible determinations from learners, especially Jean, to shift their discourse from colloquial to literate, particularly in Irish. Also, considering learners' word use in English remains mainly passive-driven, it appears that their word use tends towards literate and phrase-driven when communicating about functions individually through Irish. This discursive shift in word use is an indicator of meta-level thinking (Sfard, 2008; Moschkovich, 2002). However, although a shift from colloquial to literate discourse is evident, there is little evidence of objectified talk, even when Irish is utilised as the primary language of communication.

This study demonstrates that students utilised their languages in different ways when engaged in the same discourse (Kim et al., 2012), with greater evidence of meta-level thinking evident through the medium of Irish. Interestingly, both students show more competency and mathematical skills when using Irish in their individual explanations of the routines they employ to solve the problems and begin to shift towards a more literate and less colloquial discourse. In contrast, when engaged in conversation in English about the mathematics problems, they remained at a colloquial level of word use. In both instances, Irish was the preferred language utilised in the individual interview, whereas English was the language utilised during the paired interview. Although Jean displayed more dominance in mathematical discourse in the individual interview in Irish, this is not shown in the paired interaction. Jean does not use the same words nor employ the same visual mediators to explain the domain of function  $f$ . This might suggest a gap in Jean's discourse perhaps pertaining to meta-level understanding of the question, mathematical competency, or linguistic ability to discuss mathematics through English. Although learners displayed competence in terms of ritual-based routines from previous learning, either at university or school, reliance on such processual thinking resulted in occasional errors, or highlighted a lack of meta-level thinking when endeavouring to substantiate a particular narrative, in either language. This study demonstrates the importance of studying bilingual learners in diverse contexts in order to gain a better understanding of the intricacy and impact of their languages on mathematical thinking (Planas & Setati, 2009).

Overall, these students' mathematics discourse followed a basic language trajectory when engaged in functions discourse in English and collaboratively, whereas their mathematics discourse tended towards a more advanced mathematics discourse trajectory when engaged in functions discourse in Irish and individually. However, despite their mathematical language use progressing in Irish, this does not equate to progressing towards meta-level thinking, in either language. This insight raises additional questions relating to bilingual mathematics students' learning, in particular the role of the teacher in developing students' discourses and if there is value in explicitly teaching meta-level thinking/rules (Gücler, 2016) as related to language use by bilingual learners in undergraduate education. In addition, the social setting impacted on students' language choice in this study and

raises the more general question of how the context of bilingual undergraduate mathematics learning influences choices relating to language use in bilingual mathematical discourse.

## Acknowledgment

This paper is dedicated to the memory of our wonderful participant and dedicated student, Val. The project is funded by the Irish Research Council–New Horizon’s Research Grant (REPRO/2015/53).

# Specialized language support in mathematics education through the use of radio resources

Franziska Peters

Justus Liebig University, Department of Mathematics Education, Giessen, Germany

franziska.peters@math.uni-giessen.de

*This paper offers insight into my pilot study on the use of radio features for specialised language support in mathematics education at the primary school level. With the help of design research, various possible applications of radio resources as auditory learning material are developed and analyzed. One example is described in this paper. The aim of this research is not only to investigate the effects of auditory material on the learning procedure in general, but also to investigate how auditory material can serve as a supportive language example and as a provided language model. First results show that auditory material can indeed be effectively implemented in teaching practice and reveal just how these effects look like.*

*Keywords: Auditory learning, radio resources, design science, language support.*

## Background: Cooperation with a radio station

In 2015, the Department of Mathematics Education at the University of Giessen started a project in cooperation with a regional radio station “hr2 – Hessen Radio for Culture”. This radio station developed, inter alia, a series of radio broadcasts on mathematical topics for the primary school level, collected in the multimedia offering “Kinderfunkkolleg Mathematik” ([www.kinderfunkkolleg-mathematik.de](http://www.kinderfunkkolleg-mathematik.de)). Within this collaboration project, future mathematics teachers developed auditory material for use in mathematics education at the primary level. More information about this first project can be found in the proceedings of the ERME topic conference 2018 (Peters, 2018). In a second project, future mathematics teachers planned teaching units for performance in schools, using auditory educational material as a central element. It was important to interrupt longer listening phases and repeat the segments while giving listening tasks in between. The auditory material could be used as preparation of a topic or as a base for discussions, as well as for explaining and deepening new content or repeating previously covered topics. The units were realised in different schools, reflected on in the seminar, optimized and then turned in. After being corrected and edited, the units were then allocated for the download center of the “Kinderfunkkolleg Mathematik,” as accompanying material. Based on this project, I started developing research aims and the design of my pilot study to further research on the effects of radio resources as auditory learning material. The material, used in this study is developed and owned by professional radio authors and producers who received help from experts in our university department.

## Auditory learning

In order to research the effects and the use of auditory material, one has to understand how auditory learning is working. According to Baddeley (2007), in the working memory visual and auditory information are processed in different sensory channels. Auditory learning reduces sensory impressions on the visual channel, so that the auditory channel is required and therefore trained more.

Acoustic information is processed through various memory processes. The echo memory saves mostly unprocessed sensory impressions for a short period of time. In a next step, the working memory with its limited capacity decodes and processes the acoustic information. It can also build temporal connections that are necessary for remembering the beginning of a sentence while hearing its end (Leuders, 2011). According to Leuders, an increase in efficiency of the working memory is a training effect. Since the processing of auditory information takes place in the working memory, one can assume that the increase in auditory learning efficiency is a training effect. This is a fundamental trigger for my interest in research on auditory learning materials in mathematics education.

Another important aspect is the Cognitive Load Theory by Sweller (1994), more recently taken up by Rink (2014) for the research on digital media in mathematics education. The Cognitive Load Theory says that the capacities of the working memory are limited and should not be exhausted by extrinsic factors. One of those extrinsic factors is reading. Reading difficulties can exhaust the working memory and lead to not understanding mathematical content as well as not being able to solve mathematical tasks. Keeping mathematical concerns in the center of learning processes while reducing extrinsic factors, is one important approach for auditory learning. That's why Rink (2014) uses audio recordings as a support for solving written tasks.

### **Auditory learning material**

As a first function, it can be stated that auditory support can aid children with reading difficulties to understand mathematical contents and tasks without the need of having to read coherently and extract the meaning. This, however, does not mean that reading should be replaced by hearing. Auditory support should only be provided if needed.

Another function of the use of auditory material is the development of active listening skills. Such competence is a primary requirement for education, but it is seldom supported or even trained (Pimm, 1987). In Germany, education standards for the subject of German language make it very clear: These require, not only the competences of reading and writing, but also speaking and listening. Speaking is required to be consciously organized, while terminology is to be trained and (the use of) language is to be examined. Regarding listening, children are to listen attentively and perceptively, while registering others' statements and constructively dealing with them. Of course, listening also takes place in the form of frontal teaching, but this kind of listening is difficult for most students. This is why supportive elements for auditory learning are necessary – both in frontal teaching and by means of group work.

### **Mathematics register acquisition**

The mathematics register can be seen as “consisting of technical terms, diagrams, and grammatical constructions, such as logical connectives” (Meaney, Trinick, & Fairhall, 2012, p. 199). These elements are learned throughout the entire school process and students are constantly “introduced to further layers of meaning for the terms and expressions they already know” (Meaney et al., 2012, p. 199). Leung (2005) points out that learning vocabulary in mathematics means learning both formal and semantic features of words in various contexts, and involves thinking with and through the concepts. She calls it an “incremental activity” (ibid.), stating that meanings can develop and expand.

The model for mathematics register acquisition (MRA) was developed to categorize teachers' strategies in teaching the mathematical register and is divided into four stages (Meaney et al., 2012). The first stage is "Noticing". In this stage, teachers introduce new terms or expressions, use them frequently and then encourage students to use them as well. The second stage, "Intake", describes the process of understanding. Students start to explore and work with the new terms. In the next stage titled "Integration", testing, feedback and modification takes place. Students have a good understanding of the new term and are responsible for using it, but might be supported or reminded of their knowledge. In the last stage, "Output", there is a fluent use of the new terms. Teachers do not need to support, but should provide activities where the use of these terms would arise naturally. The control of teachers and support through scaffolding is only necessary in the first two stages; in the final two stages, students gain control. The teacher only needs to provide opportunities to use the new terms. Regarding auditory material, we can see that it can be of use in the first two stages. It can be used to introduce new terms and to repeat them frequently in the stage "Notice". In the stage "Intake", it can serve as a language model with which students can work.

### **Specialized language support through auditory material**

As already mentioned, the learning of a language can be supported by training listening competence. Active processing is important for meaningful processing and for memorization of what has been heard. Reasonable and profitable use of auditory material is needed for these processes, e.g., good embedding, listening tasks or segmenting principle. With this in mind, teaching concepts can be developed, in which radio features or other auditory material serves as impulse in the sense of didactical reduction. As acoustic representations are volatile, there is the need of adding opportunities to document the content of the heard and results of the related tasks within the teaching units. By these means, specialized language support can be ensured. Following these ideas, my research can be focused on the evaluation of auditory educational material in various settings, particularly regarding possible learning effects. The main interest of this research is the use of radio features in mathematics education for specialized language support at the primary level.

Prediger and Krägeloh (2016) refer to a model of three registers relevant for mathematical learning (everyday register, school register and technical register). This model illustrates different levels of verbal representation and how they are connected or built onto each other. Particularly interesting for my research is the question of how children can be led from everyday register to school or even technical register.

School register is an important and necessary factor for successful learning in mathematics. It is a shared language basis and helps with explaining, describing and justifying (Götze, 2015). However, children do not bring this type of language to school with them. It must be learned, like registering a new language. This applies not only to children with special needs in language development but to every other child. That is the reason why they need linguistic models to develop educational language and to fill terms with representations. These linguistic models are scaffoldings onto which children can lean (Gibbons, 2002). Lexical storages, which only include words, are not sufficient, as new terms must be used in whole phrases and sentences. According to Götze (2015), language acquisition is, in practice, merely a continuous learning process. There can be setbacks and sometimes children express

themselves better in written than in spoken language. This is because everyday register is predominant in spoken language and, oftentimes, deictic expressions are used. This is valid for children as well as for teachers – even if they do so unaware and unintentionally. At this point, auditory educational material could be a useful and profitable addition.

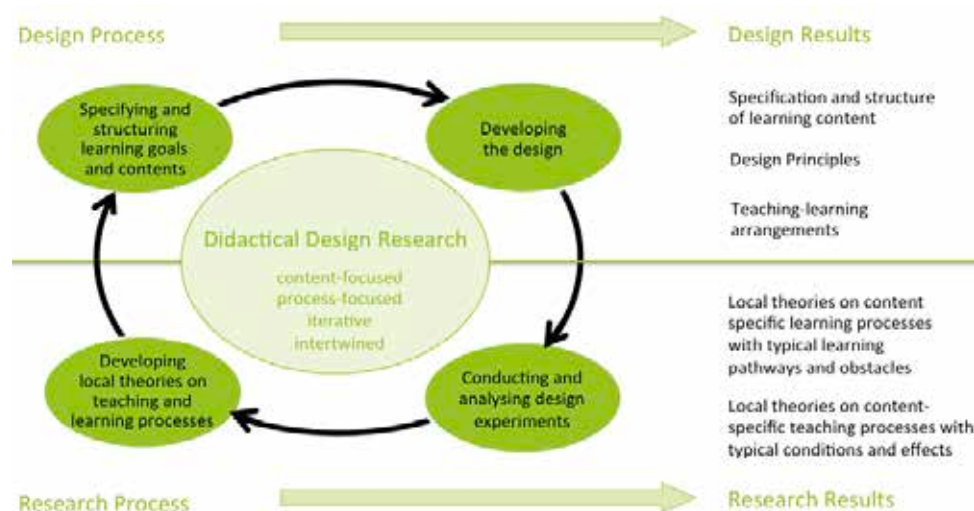

## Research questions

The aim of my research is to find out in what way auditory learning material could be of use for language support in mathematics education. For this cause, I want to ask how auditory material, as a language model, can stimulate the development of the school register and how auditory material can support listening competence. In a second step, I want to research what a profitable use of such material could look like.

## Methodological approach

Regarding the data collection, I decided to use the design research, based on Wittmann's Design Science (1995). Subject of the Design Science is the construction and research of teaching concepts, including accompanying theories. According to Wittmann (1995), this science is a practice-oriented core area for mathematical education, since it refers to the construction of artificial objects (teaching concepts, curricula etc.) and the research on possible effects in different educational settings.

Based on the Design Science, Prediger et al. (2012) developed the model of design research. The aim of this method is to effectively implement innovations for educational development in teaching practice and empirical research, carried out under realistic conditions. In order to do this, one has to undergo a cycle as pictured in the following illustration.

**Figure 1: Model for didactical design research (Prediger & Krägeloh, 2016, p. 95)**

The cycle starts at the upper left side of the illustration with the specification and structuring of the learning subject. In my case, this would be the mathematical content of the used auditory material, which will be specified later in the explanations of the pilot tests. Learning goals have to be developed and the content has to be structured matching those goals. This also means, that important sequences of the feature have to be chosen and cut as the whole feature is far too long (10-12 min) for a profitable use in classroom. Based on this preparatory work, a design is to be developed for the specific learning

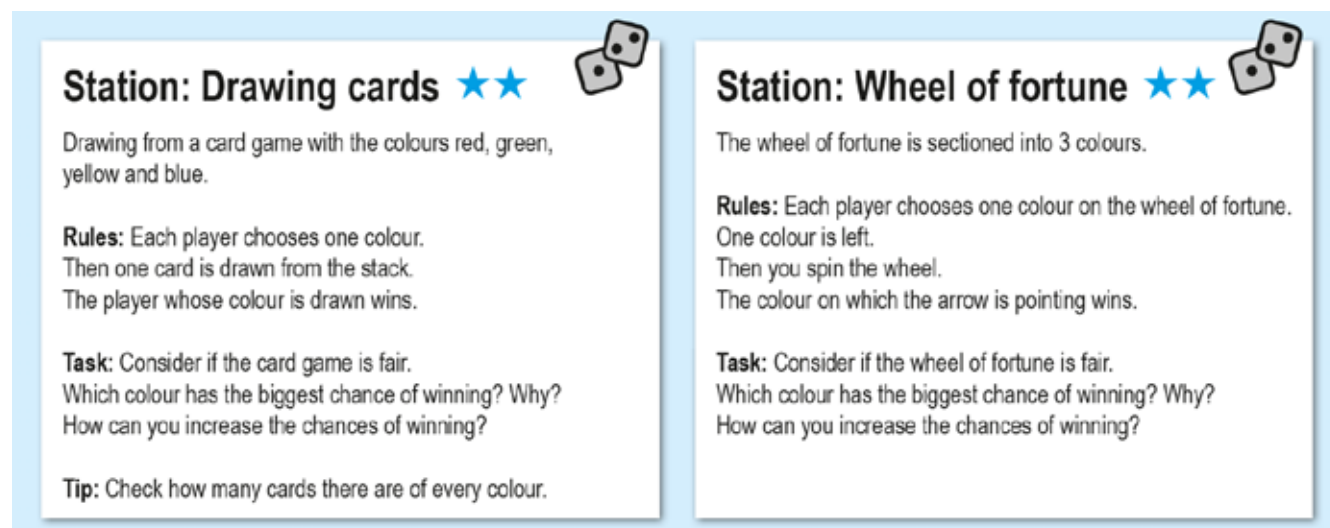

topic of the used auditory material. In a third step, the developed design is to be performed by means of a design-experiment. In this phase, the concept was tested in teaching practice, data was collected by filming and said data was evaluated. To analyze the student's utterances, the analysis of interaction is used (Krummheuer & Naujok, 1999). Based on the analysis of this data, local theories about the learning subject and the teaching concept can be developed in the last phase. The local theories are the starting point for next rounds of the cycle, in which they can help to optimize the learning goals and concept. Later on, they can be developed to or lead to new local theories itself. Thus, more experiments, data collections and evaluations are to follow, along with new local theories. In this way, after a few cycles, we will not have a perfect teaching concept or representative research results, but rather new and tested theories on the use of auditory media for specialized language support. By now, I finished the first cycle and am currently using my initial experiences to develop local theories, as well as structure the learning goals and teaching concepts anew for the second cycle.

## **Pilot testing**

For the pilot testing, I designed a teaching unit in the form of a project day in a fourth-grade classroom with four 45-minute classes. The class is made up of 16 children, all of whom participated in this project day. A teacher, who was specially trained for this project, instructed the unit. The topic of the unit was "Probability and Random Experiments", as it was developed based on the radio feature "Wann ist ein Spiel fair?" (When is a game fair?) from the Kinderfunkkolleg Mathematik (<https://www.kinderfunkkolleg-mathematik.de/themen/wann-ist-ein-spiel-fair>). In this feature, four students are planning to play a game in order to make a decision. They realize the need to test the fairness of the game, start an experiment to do so and find out that the game is unfair, since they don't have equal chances. While testing the game and talking about the mathematical problem, they use school register and mathematical terms. Thus, the students in the class that was observed and filmed were confronted with new terms in a playful way. The overall aim of the unit was the conceptual development of "fairness" (through language) while the linguistic aim was the understanding of the following terms which were presented in the radio feature: double, street (as the subject of the feature was a dice game with the winning options "double" and "street"), probable, option, coincidence, fair, unfair, unsafe, unlikely, likely and safe. Those aims work together: language development can help to develop the concept. Throughout the entire day, both the class situation as well as the working phases in smaller groups were filmed. This way, enough data was gathered referring to the individual processes of the children's speech development, while at the same time it was possible to research on what a profitable use of this material could look like. For the second testing, these experiences can be used to improve the unit and the use of auditory material.

The first lesson began by listening to the first part of the radio feature in which two children were arguing about the fairness of a dice game. In class conversation, the students repeated the content of the heard, reviewed the game and tested the fairness of that game in various steps that built on one another. In between those steps, more parts of the radio feature were presented, and a lexical memory was collectively developed based on the content of these features. In the second part of the day, the students verified the chances of winning and determined the fairness of various other games during learning stations. Hereby, they had to transfer their acquired knowledge whilst using the structures of language and reasoning they had been offered and trained through the radio feature. In Figure 2, you

see two exemplary stations referring to game fairness. Other stations were about dicing with different winning numbers and about dicing with six- or ten-sided dice, about throwing different amounts of reversible tiles and about picking different colored balls from an urn.

**Figure 2: Exemplary stations of the learning stations**

In groups of two, students chose a game for which they would be experts. Each group had to test every game, but they only had to work on a worksheet for their expert station. On that worksheet they had to describe and to reason whether or not that specific game was fair or unfair. If the game was unfair (which all of them were), they also had to explain why the game is unfair and how one could make this game fair i.e. how to increase the chances of winning for the losing card, colour etc. so that the chances become equal. After the learning stations, students ended the unit with the presentation of their “expert stations”. Each group presented their station, outlined how they examined the game and shared their results. They also presented a solution on how to make the game fair.

## Initial experiences

Initial observations showed that students were highly concentrated while listening to the radio features. Due to the fact that students know audio-plays from their everyday life and free time, this proved to be highly motivational and made the mathematical content more exciting. The feature and its “story” involving mathematical content served as an effective conversation starter for the students’ discussion. It can already be reported that the method is currently being adjusted for the second cycle of the design research by designing the testing more as a laboratory situation and less of a whole teaching experiment. In that way, it is possible to research more about the individual processes of the speech development of the children. Still, it can already be stated that nearly every student was able to correctly repeat what he or she had heard. If anything was unclear, it was easy to repeat a certain part of the radio feature individually or in front of the whole class. In this way, auditory material can counteract transitory learning through possible repetition. Through the combination of listening, repetition (if needed) and conversation, the use of radio features successfully aided the development of lexical memory and was helpful when introducing new terms. In the beginning of the unit, the students were only able to explain abstract terms such as “fair” with help of examples:

Teacher: So what actually is fair?

Student 1: Uhm fair is.. mh.. when you say for example if t w o uhm for example o n e gets a gummi bear and the other one not then they find this unfair and fair is if the other one also gets a gummi bear.

This explanation could be considered a form of everyday register, as the speaker describes an everyday example using everyday register. However, this changed throughout the four hours of the project. During the final presentation of their investigated games, the students were allowed to look at their worksheet and their written answers for support. Interestingly, they did in fact use the new mathematical terms and phrases while arguing about the game's fairness.

Student 1: Uhm it's unfair because uhm the game is unfair because there are eight of blue, one of red, red of two uhm.. red two of them.

Student 2: No there's only one of red.

Student 1: Yes. Two of green and four of orange. Because you have more chances with blue and the others have less.. (reads the next question) *If the game is unfair, what would you have to do to make it fair?* You'd have to change the game so that everybody had equal amounts of uhm cards of every colour then everyone would have equal chances and the game would be un uhm fair.

Teacher: Very good, thank you.

Here we see that the speaker uses school as well as technical register. Mathematical terms and phrases, such as, "It's unfair because...", "more chances", "equal amounts of..." and "equal chances" – that appeared in the radio feature when the protagonists were examining their dice game – are not only used by the students, but also used correctly. Referring to the MRA model explained above, there has been a development from the stage "Noticing" – where new terms or expressions are introduced – to the second stage "Intake" – which describes the process of understanding. There are also first elements of the third stage "Integration", as there is testing, feedback and modification in the investigation of the game's fairness. To reach the last stage "Output", the children would need to be able to use the new terms fluently without support. In this case, the children still have the support of their written answers on their worksheets while presenting their results, so we are unable to tell for sure if they reached this stage. However, it is clear that there is a development from stage one to three – from noticing to integration. This indicates that there is an apparent improvement in the students' mathematical expression throughout the teaching unit. Children are offered professional language and are thus challenged to intake and use it. The absence of visuals, gestures and deictics in auditory material (unlike YouTube videos etc.) is a big challenge and opportunity for language development which worked out in my pilot testing quite well. Thus, as a first conclusion, it can be stated that radio features or auditory material in general can indeed serve as verbal language support in mathematics education. The goal of my main study is to verify and specify this statement for other mathematical topics, to further research on the use of the features in laboratory situations and to develop various possible applications of radio resources as auditory learning material.

# Classroom communication: Defining and characterizing perpendicular lines in high school algebra

Valentina Postelnicu

Texas A&M University-Corpus Christi, USA; [Valentina.Postelnicu@tamucc.edu](mailto:Valentina.Postelnicu@tamucc.edu)

*A study was conducted with a high school algebra teacher and her students with the purpose of gaining insight into the students' difficulties with perpendicular lines. The study reported here focuses on the communication between the teacher and her students, and the nature of their messages. Classroom observations were conducted, and a written task was administered to students. The communication was analyzed using constructs from Hall's theory of culture. The analysis revealed that the teacher's messages were not received by her students in the way intended by the teacher. The students had difficulties defining perpendicular lines, representing graphically and characterizing them algebraically, and connecting between representations.*

*Keywords: Classroom communication, perpendicular lines, high school algebra.*

## Introduction

Research on students' difficulties with perpendicular lines and linear equations in the context of high school algebra is scarce (Postelnicu, 2017). Some studies point to students' difficulties with graphical representations and connecting among various representations (Arcavi, 2003; Knuth, 2000), and teachers' failure to identify the nature of their students' difficulties in geometric context (Gal & Vinner, 1997). The purpose of this study is to gain insight into the students' difficulties with perpendicular lines and their equations in the context of high school algebra, as it is taught and learned in a public school in the United States. The focus is on the mathematical knowledge constructed during the classroom interaction (Steinbring, 2005), i.e., on the communication between the teacher and her students, the nature of their messages, and their different interpretations of those messages. Nührenbörger and Steinbring (2009) studied the different interpretations by the teacher and two students of a mathematical statement, and pointed to the dominance of the teacher's ideas during the observed interaction. In the study reported here, the relations between the teacher's language (her messages), the language of the learners (students' messages), and the language of mathematics (textbook's messages) (Planas, Morgan, & Schütte, 2018; Planas & Schütte, 2018) are studied using Hall's (1959) theory of culture.

## Theoretical framework: Hall's theory of culture

The teaching and learning of mathematics are cultural activities that take place in various institutions (e.g., the classroom from this study). The theoretical framework used to analyze the classroom culture abides by several principles (Hall, 1959):

**i) Culture is equivalent with communication.** "Culture is communication and communication is culture" (Hall, 1959, p. 217). This principle of equivalence between classroom culture and classroom communication, allowed us to account for the teaching and learning of mathematics in the observed

classroom by analyzing the communication between the teacher and her students. The idea of equivalence between doing mathematics and communicating mathematically is also found in Sfard (2008).

**ii) We communicate through messages.** A message is constituted by *sets* communicated in *patterns*. *Sets* are constituted by *isolates*. When one communicates using a language, one uses words (*sets*) that are made of sounds (*isolates*). The words are communicated in some context using a specific syntax (*pattern*) “in order to give them meaning.” (Hall, 1959, p. 124). Old words, communicated using a *pattern*, are used to give meaning to new words. When we learn a new language, the words (*sets*) are perceived first. It takes time to understand the *pattern* of communication in a new language and construct meaningful sentences. As well, it may take a long time to master the sounds (*isolates*) of the new language and pronounce them without the accent from the old language. At the academic level, the mathematical knowledge is communicated in statements like axioms, definitions, or theorems. These statements constitute the *sets*. Examples of such *sets* are the definition of perpendicular lines, or the theorem of algebraic characterization of two perpendicular lines. The *isolates* are the mathematical objects and their properties - like line, slope of a line, lines that intersect to form a right angle. In scholarly mathematics, the *pattern* of communication is the formal proof; it gives meaning to statements/theorems. Old statements, already accepted as true, are used to logically derive new statements, using the accepted rules of inference. Oftentimes, when validating a new statement, the steps of the argument are expressed in natural language and employ previously validated statements (e.g., see Postelnicu (2017) for an example of a proof of the theorem of algebraic characterization of two perpendicular lines described as a “Key Concept” in Table 1, below). The communication *pattern* changes with the cultural context/institution. In school mathematics, the *pattern* of communication may be a justification (e.g., see Wallace-Gomez & Miller (2011) for a visual justification of the “Key Concept” from Table 1, below). In United States high schools, researchers point out that proofs are found mainly in geometry courses, and are almost non-existent in algebra courses (Martinez & Superfine, 2012). In the study reported here, the participants used an Algebra 1<sup>1</sup> textbook (Larson et al., 2007) that contains mathematical statements (e.g., “key concepts”) without proofs. The *pattern* of communication consists of stating the “key concepts” and providing examples of algorithms to execute tasks.

**iii) We can only observe a message at one level of communication at a time.** When a message is communicated from one cultural context to another, its meaning may change. As observed in this study, the message changes when the level of communication changes (from textbook to teacher, and from teacher to students). Consequently, it is imperative to account for the way the textbook message (with its *pattern* of communication, *sets*, and *isolates*) changes into the teacher’s message, and then into the students’ message.

## Methods

The study reported here is part of a larger study with an Algebra 1 high school teacher and her students from a public high school in the United States. The study lasted four weeks and included a teaching

---

<sup>1</sup> In the United States, students take the first algebra course before the geometry course.

experiment with multiple episodes, with the author as a witness (Steffe & Thompson, 2000), classroom observations carried out by the author (Erickson, 1985), and the administration of various written tasks to students. Only 58 students out of 137 agreed to have their answers reported in this study. The focus is on the classroom communication, as observed by the author, the day after the teacher communicated to her students the definition of perpendicular lines and the “Key Concept” about the slopes of perpendicular lines (described in Table 1, below). The author observed all six classes taught by the teacher in one day, took observation notes, and collected copies after the students’ written answers to the following task administered by the teacher, **Task 1**:

- “a) Sketch the graph of the line that is perpendicular to  $y = \frac{3}{4}x - 2$  and goes through the point (2, -6). What is the equation of the new line you created?
- b) How did you determine this?
- c) A fellow student does not understand what perpendicular lines are. Explain to them in as much detail as possible what perpendicular lines are and how you find them.”

Before administering Task 1, the teacher assigned a warm-up task on parallel lines, similar to Task 1a<sup>2</sup>, and solved it on the whiteboard. She also included in her the post warm-up communication a review of the knowledge on perpendicular lines, necessary to execute Task 1a. Students’ written answers to Task 1 were collected. Due to space constraints, I analyze only Task 1c. In my analysis I refer to the connections between Tasks 1a, 1b, and 1c.

## Analysis and results

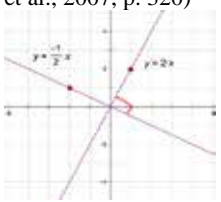

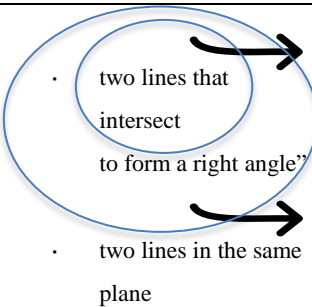

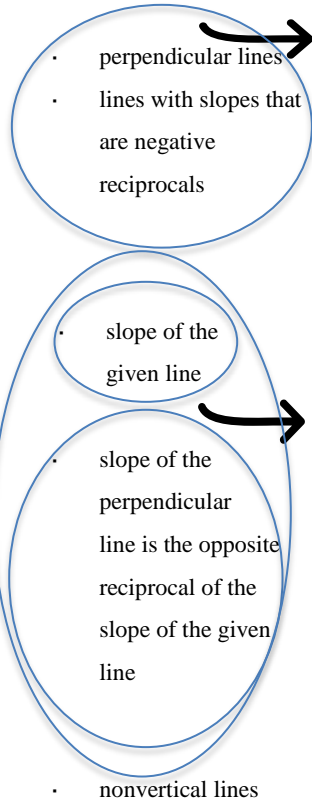

Table 1, below, represents the levels of communication taken from the Algebra 1 textbook (Larson et al., 2007), the author’s observation notes on the teacher’s communication with her students, and the students’ written answers to Task 1c. The analysis considers the messages at each level, as well as the changes in message from one level to another. The messages are decomposed in *sets* (titled in bold, for example **Statements 1-4**, at the student level), and the *isolates* are presented with bullets. The textbook messages are presented in the first column from Table 1, followed by the teacher’s messages, preceded by “T:”. The teacher’s messages were subsets of the textbook messages, hence the presentation in the same column from Table 1. The Venn diagrams and the arrows illustrate the change in message from the teacher level to the student level. Table 2, following Table 1, presents examples from the students’ written answers on Task 1c. Each of the **Statements 1-4** is accompanied by **Examples** from the students’ answers. For continuity of presentation, Table 2 restates in its first columns the student messages (*sets* with their *isolates*), exactly like in Table 1. The analysis follows each message (*set* and its *isolates*) horizontally in Tables 1 and 2, respectively. As mentioned before, when one encounters a new language, the words (*sets*) are perceived first, therefore the analysis was conducted at the level of *sets*.

It can be seen in Table 1 that in the context of Task 1c, three *sets* were communicated at the textbook and teacher level: the definition of perpendicular lines, the “key concept” stating the theorem of algebraic

---

<sup>2</sup> Sketch the graph of the line that is parallel to  $y = \frac{1}{2}x - 3$  and goes through (2, -1).

characterization of two perpendicular lines, and the first step of the algorithm for executing Task 1a, the step referring to identifying the slope of a line perpendicular to a given line. Each of those *sets* are analyzed at the textbook, teacher, and student level. It can be observed in Table 1 that the *sets* at the student level were constituted from the *isolates* at the textbook and teacher level.

\* (N=35), after Statement 1, represents the number of students who communicated that statement.

**Table 1: Representation of levels of communication**

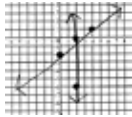

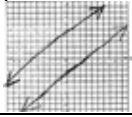

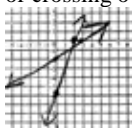

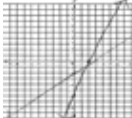

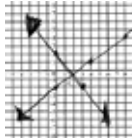

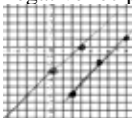

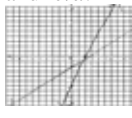

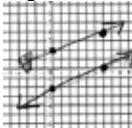

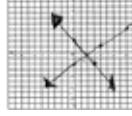

The first *set* in Table 1 (column 1) defines perpendicular lines. The textbook marks one of the right angles formed by two perpendicular lines in a graphical representation similar to the one from Table 1 and points to the “Key Concept” necessary to execute Task 1a (a  $90^\circ$  rotation of a line generates a perpendicular line, and the two lines have slopes that are opposite reciprocals). At the textbook level, the definition contains *isolates* like “two lines in the same plane” and lines that “intersect to form a right angle” (Table 1, column 2). At the teacher’s level, the *isolate* “two lines in the same plane” was omitted, and the right angle was sometimes referred to as a “ $90^\circ$  angle.” As noticed in Table 1 (columns 2 and 3) at the student level, the teacher’s *isolate* referring to two lines that “intersect to form a right angle” changed into two *sets*, **Statements 1** and **2**, the first referring to intersecting lines and the second referring to intersecting lines that form a right angle. Consequently, more than half of the students ( $N=35$ ) defined perpendicular lines as lines that intersect. The *isolate* “line” was not problematic for students with respect to their graphical representations (all students graphed lines), but the other *isolates* from **Statement 1**, “two lines” and “two intersecting lines” posed difficulties. The examples accompanying **Statement 1** in Table 2 suggest the following difficulties: i) conceiving of the second line, given one line (**Example 1**, “a perpendicular line is a line that intersects with something”); ii) connecting between representations (parallel lines were represented in **Example 2**, but described as “lines that intersect, they both share the same point,” and parallel lines that “do not ever touch” were described in **Example 3**, where intersecting lines were graphed); iii) conceiving of the intersecting point (the point of intersection was mentioned in three of the students’ answers but was not marked in any of the students’ answers, making questionable the meaning of “intersecting lines” in answers like in **Example 4** where intersecting lines were described as “touching or crossing over each other”).

Continuing with the **Statement 2** in Table 2, only six students mentioned “lines that intersect to form a right (or  $90^\circ$ ) angle, three of them did not have matching graphical representations (see **Example 5**, where the lines intersect but do not form right angles), and three of them had matching graphical representations like in **Example 6**. The analysis of the students’ answers including **Statement 2** indicates that while the *isolate* “two intersecting lines” did not pose difficulties, the *isolate* “right angle” was problematic. This issue raised the question if the difficulty was limited only to the measure of the angle or if it extended to the concept of angle itself.

To execute Task 1a, one needs the theorem of algebraic characterization of two perpendicular lines in a Cartesian system of coordinates (see the “**Key Concept**” in Table 1, column 1), and the algorithm to apply it (see also the **Algorithm for Task 1a (Step 1)**). At the teacher level, the theorem was stated “Perpendicular lines have slopes negative reciprocals,” and sometimes “negative” was replaced by “opposite” to emphasize that the slopes of perpendicular lines have opposite signs. The *isolate* “nonvertical lines” was not mentioned by the teacher during classroom observations. As mentioned in **Methods**, the teacher reminded her students how to determine the slope of the line perpendicular to the given line  $y = (1/2)x - 3$ , by finding the opposite reciprocal of the slope of the given line: “You take the slope of the original line,  $a/b$ , that is  $1/2$ , flip it,  $b/a$ , that is  $2/1$ , and change its sign,  $-2/1$ .”

The teacher matched the algebraic and graphical representations (see the last figure in Table 1, column 1). The students used the *isolates* from the teacher level (Table 1, column 2) to constitute their *sets*,

**Statements 3 and 4** (see Table 1, column 3). **Statement 3** refers to a characteristic property used by students to define two perpendicular lines, while **Statement 4** refers to the algorithm of finding the slope of a line perpendicular to a given line,  $y = mx + b$ . None of the students who stated the property from **Statement 3** used it correctly in the algorithm described in **Statement 4**. Although the students mentioned “slope” and “negative reciprocals,” they failed to identify the slope of the given line or its negative reciprocal. Therefore, the students’ answers were reported separately for **Statements 3 and 4**.

Communication at the student level		Examples from the students’ written answers	
Sets	Isolates		
<b>Statement 1 about intersecting lines:</b> Perpendicular lines are lines that intersect. (N=35)	<ul style="list-style-type: none"> <li>line</li> <li>two lines</li> <li>two lines that intersect</li> </ul>	<b>Example 1:</b> “A perpendicular line is a line that intersects with something.” 	<b>Example 3:</b> “Perpendicular lines are lines that are side by side and do not ever touch each other.” 
<b>Statement 2 about intersecting lines forming a right angle:</b> Perpendicular lines are two lines that intersect to form a right ( $90^\circ$ ) angle. (N=6)	<ul style="list-style-type: none"> <li>two lines that intersect</li> <li>angle</li> <li>right angle</li> </ul>	<b>Example 2:</b> “Perpendicular lines are lines that intersect, they both share the same point.” 	<b>Example 4:</b> “Perpendicular lines are lines that are straight but are touching or crossing over each other.” 
<b>Statement 3 about the slopes of perpendicular lines:</b> Perpendicular lines have slopes that are negative reciprocals. (N=8)	<ul style="list-style-type: none"> <li>perpendicular lines</li> <li>slope</li> <li>negative reciprocals</li> </ul>	<b>Example 5:</b> “Perpendicular lines [...], the intersection of the lines form $90^\circ$ angles.” 	<b>Example 6:</b> “Perpendicular lines- lines that intersect with a $90^\circ$ angle.” 
<b>Statement 4 about finding the slope of a perpendicular line:</b> To find the slope of a line perpendicular to a given line, you find i) the slope of the given line, and ii) the negative/ opposite reciprocal of the slope of the given line. (N=28)	<ul style="list-style-type: none"> <li>given line</li> <li>slope of the given line</li> <li>the negative/ opposite reciprocal of the slope of the given line</li> <li>perpendicular line</li> </ul>	<b>Example 7:</b> “A perpendicular line are 2 nonvertical lines that have negative reciprocals.” 	<b>Example 8:</b> “Perpendicular lines are two nonvertical lines that have negative reciprocals. Slopes are $a/b$ and $-b/a$ .” 
		<b>Example 9:</b> “Perpendicular lines touch, you must flip the sign and make it a negative.” 	<b>Example 10:</b> “Perpendicular lines- lines that intersect with a $90^\circ$ angle. In order to find them you need to plot the original $y = \frac{1}{2}x + 3$ , then make everything opposite of that, $y = -2x + 3$ , then graph.” 

**Table 2: Representation of the communication at the student level**

Only one of the eight students who referred to **Statement 3** in their answers had a graphical representation of perpendicular lines. The other answers had graphical representations of parallel lines and non-perpendicular, intersecting lines (see **Examples 7** and **8**, respectively, accompanying **Statement 3** in Table 2). In **Examples 7** and **8** perpendicular lines were described as “lines that have negative reciprocals,” and in **Example 7** “slope” was omitted. The *isolate* “perpendicular lines” remained problematic for students. Likewise, the *isolate* “slope” posed great difficulty, especially in the graphical representation. The *isolate* “negative reciprocals” or “opposite reciprocals” was used by 28 students (see Table 2, **Statement 4** and **Examples 9-10**). However, *isolates* like “perpendicular line” and “given line” and its “slope” posed difficulties for students, as shown in their graphical representations (see **Example 9** with parallel lines). In **Example 10**, the slopes of the two lines are those from the teacher’s example used in the post warm-up communication, the student wrote “make everything opposite,” although the y-intercept of the lines was not changed, and the graphical and algebraic representations did not match. Only 14 students determined correctly the slope of the perpendicular line in Task 1a, but they failed to find the correct y-intercept. Notwithstanding a minor sign error, two students found the equation of the perpendicular line from Task 1a, but their algebraic and graphical representations did not match.

## Conclusions

The communication between the teacher and her students, analyzed at the level of *sets*, showed the following features:

- 1) The lessons observed in this study were “ritualistic” and abided by the following “routine” (Lavie, Steiner, & Sfard, 2019): like in the textbook, the teacher stated the “key concepts” and presented a “model” for executing a task, then asked the students to execute a similar task. The *pattern* of communication lacked justifications or proofs.
- 2) The teacher’s messages were not understood by the students in the way the teacher intended. The teacher communicated using *sets* like those from the Algebra 1 textbook (Larson et al., 2007), but only some of the *isolates* of those *sets* were received by students. The students communicated using *sets* that were constituted from the teacher’s *isolates*, with a *pattern* lacking justification or proofs.

To overcome the effects of the “ritualization,” Lavie et al. (2019) recommend turning rituals into explorations. In our case, another way to think about teaching about perpendicularity would have been to look for *patterns* of *isolates* within each *set*. For example, in the case of the *isolate* “right angle,” one such *pattern* might have been constituting all four right angles that are formed by two perpendicular lines, pointing to their vertex and sides (to constitute the *isolate* “angle”), describing them (their measure), giving counterexamples (acute and obtuse angles), and connecting the verbal and graphical representations. An example of an exploration to justify the “**Key Concept**” (see Table 1, column 1) is described by Wallace-Gomez and Miller (2011).

# Disentangling students' personal repertoires for meaning-making: The case of newly arrived emergent multilingual students

Susanne Prediger, Ángela Uribe, and Taha Kuzu

TU Dortmund University, Germany

prediger@math.uni-dortmund.de & angela.uribe@math.uni-dortmund.de

*Empowering multilingual students for mathematics learning requires building on their multilingual repertoires. Although this claim has often been repeated, the students' repertoires and the interplay of their components have so far only been partly understood. The repertoire comprises different state languages but also different registers and representations serving as multimodal sources for meaning-making. This paper contributes to unpacking students' personal repertoires for meaning-making of mathematical concepts (comparing fractions). A qualitative study of three newly arrived Syrian immigrants' learning processes identifies (re)sources that the study subjects have that are different from those of native residents that had been found in former studies. These results show that teaching-learning arrangements should connect the registers and representations in more flexible trajectories.*

*Keywords: Multilingual repertoires, language, qualitative case study, newly arrived multilinguals.*

## Background: Disentangling personal multilingual repertoires as a research gap

### Theoretical background: Multilingual repertoire as a resource for mathematics learning

Academic and pedagogical discourses on multilingual mathematics classrooms have undergone several shifts, not only from language-as-problem and language-as-right to language-as-resource (Planas & Setati-Phakeng, 2014), but also from focusing on students' resources in different national languages from quite static perspectives to more dynamic conceptualizations carried by the construct of a person's *language repertoire* (Barwell, 2018; Planas, 2018). Blackledge, Creese, and Kaur Takhi (2014) define a person's communicative repertoire as "the collection of ways individuals use language and ... other means of communication to function in the multiple communities in which they participate" (p. 487) and emphasize its dynamic character. Disentangling these personal repertoires is crucial for teaching approaches that build upon these resources. In order to do this, we need to focus on the *communicative* role of personal repertoires but also on their *epistemic* role in the interactive construction of meanings for mathematical concepts (Prediger & Wessel, 2013). When personal repertoires are conceptualized as sources for meaning-making (Barwell, 2018), it is even more crucial that they contain different national languages as well as overlapping registers (i.e., the functional varieties of language use) tied to social practices (Halliday, 1978) and social languages (Planas, 2018). Besides these language registers, other multimodal sources such as graphical or symbolic representations, gestures, and prosody must also be taken into account as sources for meaning-making (Prediger, Clarkson, & Bose, 2016). This paper contributes to disentangling relevant sources of meanings in the personal repertoires of multilingual students with diverse immigrant backgrounds.

### Relating registers and representations as a teaching approach for building upon students' personal repertoires

Dynamic, multimodal conceptualizations of multilingual repertoires resonate with teaching approaches that outline the didactical potentials of relating registers and representations for meaning

making (see Figure 1 from Prediger, Clarkson, & Bose, 2016; similarly, Moschkovich, 2013). In many teaching approaches, teaching-learning arrangements start by activating students' informal experiences in concrete and graphical representations or familiar contexts and mobilizing their everyday languages, all of which are later systematically related to the target formal registers and representations. For multilingual students, this approach is extended to home languages (Moschkovich, 2013; Planas & Setati-Phakeng, 2014): Informal experiences and everyday language resources in home languages can be activated in multilingual mathematical discourses. Still, "meaning-making is relational" (Barwell, 2018), that is, it takes place by relating languages, registers, and representations to each other across all languages of the learners.

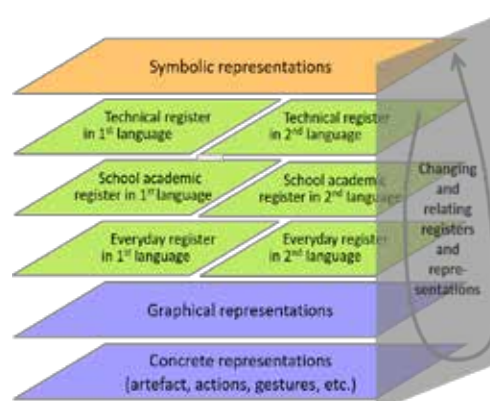

Figure 1: Relating registers and representations

Previously, based on this teaching approach, a bilingual German/Turkish teaching intervention on conceptual understanding of fractions was designed for multilingual seventh graders (native residents whose parents or grandparents born in Turkey). The study of this intervention provided quantitative evidence for the efficacy of the intervention despite the students' limited experience with the technical register in Turkish and qualitative insights into the functioning of relating languages, registers, and representations along the sketched learning trajectory from informal resources to formal learning content (Schüler-Meyer, Prediger, Kuzu, Wessel, & Redder, 2019).

In the current step of this research, the qualitative study has been extended to newly arrived immigrants from Syria. The analysis of Syrian textbooks and interviews with Syrian teachers gave indications that Syrian math classrooms prioritize the formal register and symbolic representation over the meaning-related register and the contextual and graphical representations. Thus, empirical research is required to investigate whether these different mathematical practices might influence the students' use of their multimodal repertoires.

### Research gap: Disentangling the repertoires for newly arrived students from Syria

In order to adapt the main ideas of the teaching approach of relating registers and representations to multilingual repertoires of newly arrived students, it is therefore crucial to identify these personal repertoires and their activation empirically. Therefore, the learning-process study in this paper pursues the following research question: *Which personal repertoires do newly arrived students activate for meaning-making in the subject of comparing fractions?*

### Methodological framework for the learning-process study

The research question was pursued in a learning-process study that was part of the larger mixed-methods project, MuM-Multi (Schüler-Meyer, Prediger, Kuzu, Wessel, & Redder, 2019), based on a teaching-learning arrangement developed by Prediger and Wessel (2013).

### Methods of data gathering

*Intervention.* The project investigates a bilingual teaching intervention for developing multilingual students' conceptual understanding of fractions (especially organized for the research project). The

intervention was conducted in small groups of 2-5 students each, and all groups were videotaped. The teaching material was provided in German and Arabic (or Turkish in the previous study), teachers spoke both languages.

*Sample.* The intervention addressed newly arrived Syrian students ( $n = 18$ , 12-15 years old) who are emergent German speakers (abbreviated as emergent multilinguals). Their prior formal education in Syria (5-8 years) took place in their Arabic. We present a case study of three students, Manal, Malik, and Zarah, who have learned German for 1.5-2.5 years and reached a German proficiency level of A2.2 in the Common European Framework of Reference for Languages. Among the three, Malik has the strongest mathematics achievements in the pre-test, and Zarah is slightly more proficient in German language than the others. The data was later compared to findings from the first intervention with native residents who spoke both German and Turkish ( $n = 41$ , 12-14 years old) who had grown up in Germany with no prior experience in activating their home language, Turkish, for institutionalized mathematics learning situations.

*Selected task for the case study.* While many episodes from the video data corpus were analyzed in order to identify the students' repertoires, the case study presented here is focused on the task in Figure 2. It stems from the second session of the intervention, when students had already worked on the part-whole concept. The task aims at consolidating the students' part-whole concept by addressing shares for different wholes (10 GB and 5GB) and at preparing the comparison of fractions. Subtask C follows the variation principle: Students usually solve it by either lengthening the bar in the graphical representation (the teacher then asks them to also relate this to the symbolic representation, e.g., articulating that  $7/10$  is less than  $8/10$  or that  $7/10$  must be added by  $1/10$  to reach  $8/10$ ) or starting in the symbolic representation and formally adding  $1/10$  (the teacher then asks them to also show what this means in the graphical representation). The relation of meaning-related, formal language registers and different representations is at the core of developing conceptual understanding.

### Methods of qualitative data analysis

The transcripts of the selected videos were qualitatively analyzed in two steps with respect to students' conceptual development across languages, registers, and representations:

- In Step 1, teachers' questions and students' answers were analyzed turn by turn with respect to the uttered individual theorems- and concepts-in-action (Vergnaud, 2016) on the part-whole concept and the students' emergent ideas for comparing fractions.
- In Step 2, each utterance was coded by the register and/or representation the speaker refers to and with a "+" if two registers/representations were related within the utterance or between two

#### Finding equal-sized parts in the fraction bars

Badr has already downloaded 7 GB of a 10 GB film.  
Aziza has downloaded 4 GB of a 5 GB film.

- A Draw Aziza's and Badr's parts into the fractions bars and write down the fractions for their shares.

- B Who has loaded the larger part of the whole?  
How do you see that in the bar?

- C What do you have to modify so that the parts become equal size?

**Figure 2: Fraction tasks in the case study and its preliminary solution by Zarah**

utterances. For example, “multiply,” “denominator,” and “times” are coded as terms from the technical register, “part of whole,” “colored bar,” and “equally long” as terms from the meaning-related academic register (Prediger & Wessel, 2013). Although some terms appear in different registers, their use is specific to the different registers, for example, “equally large” as a technical term vs. “equal” as an everyday term. As some English translations of terms do not exactly reflect the register character of the German or Arabic original, the original language was focused.

### Insights into learning processes of newly arrived emergent multilinguals: Case study of Manal, Malik, and Zarah and equal-sized parts of the bars

In the episode in view from the first session, the newly arrived students Manal, Malik, and Zarah work with a German- and Arabic-speaking native resident bilingual pre-service teacher (TeaA) and a German-speaking teacher (TeaG) on the comparison of fractions (tasks printed in Figure 2). In earlier tasks, the fraction bars were introduced in the download context. Prior to seeing the printed part of the transcript, the students solved Task A (see Figure 2 for Zarah’s solution), drew the colored parts of the bars and wrote down the fractions. They then discussed Task B with TeaA in Arabic: Which child has downloaded a larger part of the whole, Badr’s share of  $\frac{7}{10}$  or Aziza’s share of  $\frac{4}{5}$ . Although the graphical representation was drawn, their discussion with TeaA in Task B mainly refers to the technical Arabic register and the symbolic representation and less to the download context and related everyday language. In contrast, neither the graphical representation nor any meaning-related term, such as “share,” “part,” or “whole,” are explicitly addressed. TeaG takes over when students arrive at Task C.

45	TeaG	Now, we want to think about, how can we make this equal [ <i>points at the end of the colored parts of the bars</i> ]? How can we make $\frac{7}{10}$ and $\frac{4}{5}$ equally large? Do you have an idea?	T	graphical repr. + technical reg. + everyday reg.
46	Zarah	Five times two and four times two.	Z	symbolic repr.
47	TeaG	Yeah, you have an idea how to do this by [symbolic] calculations. But then, they are not yet equal, I think, because there is $\frac{8}{10}$ [ <i>points at the bar of <math>\frac{4}{5}</math></i> ] and $\frac{7}{10}$ [ <i>points at the shorter bar</i> ]. Do you have an idea, perhaps, when you look at the picture? Manal, you look as if you have an idea.	T	( <i>explicit</i> ): not symb., but graphical repr.
48	Manal	Aziza is very, pretty large [ <i>points at the <math>\frac{4}{5}</math> bar of Aziza</i> ]	Mn	graphical repr.

In Turn 45, the teacher asks how to modify  $\frac{7}{10}$  so that the colored part of the bar becomes equally long as the colored part in the  $\frac{4}{5}$  bar. He uses the everyday terms “make equal” and the technical term “equally large” while pointing at the graphical representation, intending to connect these three registers and representations. But his plans are not fulfilled: Zarah (in Turn 46) does not refer to the graphical representation but only to the verbalized symbolic representation. In Turn 47, the teacher acknowledges that her procedure for finding an equally large fraction for  $\frac{4}{5}$  is mathematically correct. He continues asking her to explain also how to modify  $\frac{7}{10}$  so that it reaches  $\frac{8}{10}$ , and makes explicit that he wants her to refer also to the graphical representation. This repeated hint leads Manal to refer to the expected representation: Manal uses the graphical representation as the source for the comparison of fractions for the first time in Turn 48. Although she visibly struggles while searching for adequate German terms (“pretty great”) and does not complete the sentence in a grammatically correct form, her German is still sufficient to express her meaning-related ideas on the comparison, together with gestures. In contrast, Malik stays in the more familiar technical register:

49	TeaG	Exactly, Aziza is larger and what can we do so that Badr is equally large?	T	graphical repr.
----	------	----------------------------------------------------------------------------	---	-----------------

50	Malik	Simple, Simplify [...] 10 gigabytes.	Mk context lang. + symb repr.
...			
55	TeaG	How can you do it in the picture? <i>[hints to graphical representation]</i> [...]	T graphical repr.
56	Malik	The ten divided by two becomes five <i>[points at the longer and shorter bars]</i> .	Mk technical register, hints to graph. repr

Although Malik receives several prompts to refer to the graphical representation (Turns 49, 51, 53, 55), he talks in the technical register (Turns 50-56). His interpretation of “equally large” seems to be “of same denominator,” without satisfying the teachers’ (perhaps unusual) expectation of adding 1/10 to the bar. In Turn 56, he finally gestures to the graphical representation. The teacher tries once more to focus students’ attention to the elongation of the colored part of the bar:

57	TeaG	[...] Then [...], but this would be until here and for Aziza this would be until here <i>[hints again to the ending points of both bars of unequal length]</i> What would we have to do so that both shares become equally large We have seen, 7/10 is less than 4/5. But do you have an idea how to modify 7/10?	T graphical repr.
58	Zarah	Well, we can change this <i>[points at the eighth piece in the 7/10-bar]</i> . And then, five times two and four times two becomes eight, like that?	Z graphical + symb repr.
59	TeaG	Hmm, exactly, but what you said first, this was a very good idea. What did you say?	T strengthens graphical repr.
60	Zarah	We can here <i>[imitates the coloring of the eighth piece]</i>	Z graphical repr.
61	TeaG	Do it, actually. Because, what happens if you color this piece?	T graphical repr.
62	Zarah	That becomes equally long <i>[points at the ending points of the colored bars]</i>	Z graphical repr.
63	TeaG	Then, the shares are also equally large.	T graphical repr.
64	Zarah	Then I do this? <i>[all students now color the eighth piece in the 8/10-bar]</i>	Z graphical repr.

The teacher’s repeated prompt to focus on the graphical representation finally leads to Zarah’s idea to relate the graphical and the symbolic representations in Turn 58 (“change this”). Again, she uses a minimal set of words to address her meaning-related ideas with gestures, deictic means, and prosody, but without explicitly articulating meaning-related terms. Once she has expressed her meaning-related ideas of modifying the part of the fraction bar, she can make explicit the meaning of “equally large” in the meaning-related register describing the graphical representation: “That becomes equally long” (in Turn 62). Here, the graphical representation is used to solve the task for the first time, not only as a diagram to read off numbers. In her solution, she considers both colored bars and their relation, as originally intended by the task. After this, the teacher asks for a justification:

65	TeaG	Yes, exactly, and why are the shares equally large, then? [...]	T graphical repr.
66	Zarah	Five times two and four times two #	Z symbolic repr.
67	Malik	#Eight	Mk symbolic repr.

The teacher’s “why” question in Turn 65 brings Zarah back to the technical register and the symbolic representations (Turn 66), and Malik joins her (Turn 67). Based on her experience with mathematical practices, justification in mathematics requires symbolic representation, as she formulates in another part of the transcript. However, this time, the symbolic procedure is related to the graphical shift from one bar to the next. Thus, Turns 58-67 indicate an activity of relating registers and representations.

Some turns later, the Arabic-speaking teacher talks to the students again and they switch to Arabic. Manal admits to have not yet understood (grey letters mark Arabic parts of the transcript):

79	TeaA	[...] You do not know how to write it?	
80	Manal	No, I have not understood it.	

...			
83	TeaA	[to Malik] [...] Can you explain to her [ <i>points at Manal</i> ] how you found the result, why you have drawn one more?	T graphical repr., meaning-rel. reg.
84	Malik	Because they are equally large.	Mk graphical repr.
85	TeaA	First, this is longer and that is why she got the idea to add one.	T + technical reg.

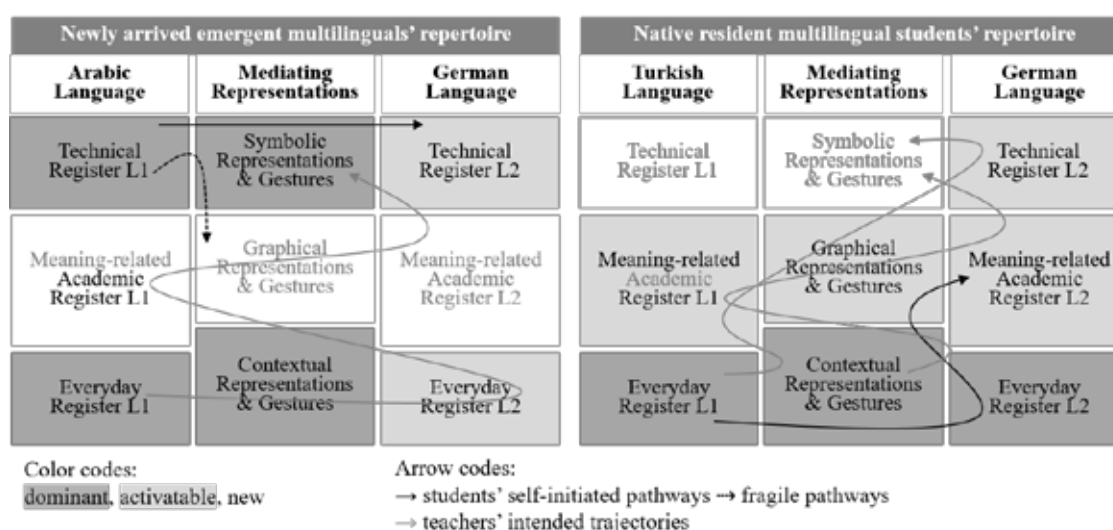

The Arabic discourse gives Manal the space to admit that she has not understood (Turn 80). The teacher makes sure that she constructs the meaning of the graphical representation (Turns 81, 83, and 85). Malik explains in the technical register what the graphical representation means (Turn 84), and then the teacher explains the graphical modification, also, remarkably, in technical terms (“add one”). During the whole discussion of Task C, the Arabic terms for “whole bar,” “colored part of the bar,” and “share” are not formulated by either the students or by the teacher.

In total, this episode shows that students and teachers activate different sources for meaning-making: Whereas the German teacher intends to construct meanings for the symbolic  $7/10 + 1/10 = 8/10 = 4/5$  by working within the graphical representation and the meaning-related register, the students show a huge distance from the graphical representation, but a familiarity with the symbolic representation and a preference for the technical register. After longer negotiations, the teacher and the students jointly construct the meaning for the graphical representations by means of the context (not shown here) and by means of the symbolic representation. This huge difference in the students’ sources of meaning-making and felt need for meaning-making for unfamiliar representations are more influential to the situation than the missing meaning-related vocabulary, which the students compensate for by gesturing and other multimodal sources.

### **Contrasting the learning processes of native resident multilingual students and newly arrived emergent multilinguals**

To contrast the presented case of Manal, Malik, and Zarah with native resident multilingual students, we draw upon findings in earlier publications (e.g., Schüler-Meyer et al. 2019) from native resident students who spoke both German and Turkish. The case study of Manal, Malik, and Zarah suggests drawing the emergent multilinguals’ repertoires in a different way: not in hierarchical levels of successive abstraction from bottom to top, as shown in Figure 1, but in three columns, where the symbolic, graphical, and contextual representations serve as mediators between the home language and German language in each of the registers, as shown in Figure 3.

Although theoretically the languages and registers could be related in different combinations, Figure 3 shows the combinations that were empirically identified. Native resident multilingual students in previous studies have often appeared to feel alienated from symbolic representation and prefer the everyday register and contextual representations, from which they access the graphical representation and the meaning-related academic register in both languages and, in the end (with teacher’s support), also the technical register and the symbolic representation. In their processes, travelling between both languages in bilingual connective modes was a major resource for their meaning-making processes (Schüler-Meyer et al., 2019; similarly in Moschkovich, 2013; Barwell, 2018).

**Figure 3: Contrasting the multilingual repertoires in parallel episodes**

In contrast, for the three newly arrived students in the current case study, connecting both languages in either of the registers rarely occurred, mainly because they strictly reserved German for the German-speaking teacher and Arabic among themselves and for the bilingual teacher. The fact that they adopted only a dual monolingual mode with rare exceptions might be traced back to the teachers' languages (Planas & Setati-Phakeng, 2014, emphasize the language context as a crucial influence) and also to the fact that their German was not yet fluent, which shows why the term *emergent bilingual* applies. Furthermore, newly arrived students who are familiar with the symbolic representation can easily transfer the basic technical terms from their home language to German. With some teacher support, they can unpack the meaning of the symbolic elements by using implicit meaning-related references to the graphical register. In our video material, all newly arrived students were acquainted to verbalizing the symbolic representations in German, and they activated this resource to construct meanings for a more unfamiliar representation.

Hence, for the investigated students, the different prioritization of representations in Syrian and German lessons appeared to have a direct impact on different uses of students' repertoires. Those who grew up in classrooms where the technical register and the symbolic representation were more valued developed other learning pathways through their individual resources for meaning making. These pathways have not yet been considered, in either the international theoretical discourse (Barwell, 2018; Planas, 2018; Planas & Setati-Phakheng, 2018) or in classroom practices in Germany.

## Discussion and outlook

As this case study has shown, students' personal multilingual repertoires can be very diverse. Whereas native resident students in Germany usually refer to contexts, graphical representations, and everyday registers as their sources for meaning-making (Moschkovich, 2013; Planas, 2013; Barwell, 2018), some of the newly arrived immigrants have strong resources in symbolic representations and thereby more quickly acquire the German technical register that their resident peers have to first get to know. In contrast, they can be unfamiliar with an emphasis on graphical representation, which is a typical shared practice in German classrooms, but not all over the world.

Although the case study is far too selective and limited in sample and scope to generalize these patterns, it already contributes to theorizing the dynamic conceptualizations of personal repertoires: repertoires are diverse and include registers and representations, beyond state languages (Barwell, 2018; Planas, 2018). We add that it should also take into account different mathematical practices in dealing with representations and registers. These theoretical extensions also have practical consequences for classrooms: Rather than planning only one learning trajectory that starts from the everyday register and concrete representations towards the formal and symbolic (Prediger & Wessel, 2013), more flexible learning trajectories should be planned. Here, we can add that for newly arrived students, it can even be beneficial to start from symbolic representations and technical registers and then continue towards graphical representations and meaning-related registers.

**Acknowledgement.** This paper was developed in the “MuM-Multi: Fostering Language in multilingual mathematics classrooms” project, funded from 2014-2020 by the German ministry BMBF (grant 01JM1403A to S. Prediger & A. Redder). We thank the colleagues for the interdisciplinary collaboration.

## Preservice teachers' reflections on language diversity

Toril Eskeland Rangnes and Andrea Synnøve Blomsø Eikset

Western Norway University of Applied Sciences, Faculty of Education, Arts and Sports,  
Norway; [tera@hvl.no](mailto:tera@hvl.no) and [anei@hvl.no](mailto:anei@hvl.no)

*In this paper, we investigate how preservice teachers (PTs) express their awareness about language diversity in mathematics classrooms. We use “language as resource” and “language as a problem” as theoretical constructs. The data is taken from PTs’ group assignments, including transcriptions of dialogues between the PTs and multilingual students, and from PTs’ written reflections about teaching in multilingual classrooms. We found that in the dialogues, PTs and multilingual students produced meanings together through negotiating a shared repertoire from out-of-school and in-school mathematics context. Nevertheless, the students’ home languages were not evident as resources in PT’s dialogues and reflections. A deficit perspective was present in their reflections. These findings lead us to rethink our teacher education courses so that language as a resource becomes more prominent.*

**Keywords:** *Language as resource, language as problem, preservice teachers.*

### Background

In this paper, we explore preservice teachers (PTs) understandings of how to teach mathematics in multilingual classrooms. In particular, we consider if, and how, they used the construct of “language as a resource” in their interactions with multilingual students and in their written reflections about teaching in multilingual classrooms.

The construct of “language as resource” has been developed as a framework to understand how languages are used and perceived in multilingual mathematics classrooms (Planas, 2018; Planas & Setati-Phakeng, 2014). Planas and her co-authors build on Ruiz’s (1984) policy planning concepts of language as a right, as a problem, and as a resource. Ruiz focused on the resource perspective. This inspired Planas (2018) to develop a theoretical framework for exploring and theorizing how language can be seen as a resource in mathematics education. The focus on “language as a resource” has the potential to contribute to a shift away from seeing home languages, which differ from the instruction language, from a deficit perspective. This shift is also identified in CERME’S 20-year history (Planas, Morgan, & Schütte, 2018).

Nevertheless, how to understand and operationalize “language as resource” in multilingual classrooms can be challenging in teacher education, schools and in research. One attempt to do this is to use ideas about *translanguaging* in mathematics lessons. Planas (2018) described the focus of translanguaging as being on what learners do to convey meaning, on how they use all their languages, and not on the normative performance of the language of instruction. This includes “situations in which multiple mathematical sign systems, iconic representations of mathematical objects, and narratives of mathematical ideas co-exist” (p. 218). According to Planas, the concept of translanguaging supports a move from a focus on correct language to a more deliberate use of language resources in the participants’ meaning making so that they develop mathematical ideas together. This is seen as deeply connected to equality in the

classroom, as multilingual students often find themselves being viewed as lacking because their home languages are suppressed (Barwell, 2018).

### **Teacher education context in Norway and in former research**

The “ordinary” mathematics classroom in Norway has changed in the last 20 years from being monolingual to multilingual. In Norway, there are three official languages, Norwegian, Sami and sign language. Norwegian dominates as the language of instruction in most municipalities. In some classrooms with language diversity, there can be many different languages, spoken by refugees and immigrants. Often there will be students who will not have any classmates or teachers who can understand their home language. The discourse around classrooms with language diversity seems to be dominated by a “Norwegian only” attitude (Naustdal, 2017), similar to what has been identified in neighbouring Sweden, where the described discourse is “Swedish only” (Norén, 2016).

In teacher education in Norway, there has been little focus on language diversity in mathematics education. For example, in the former *National Guidelines for Teacher Education*, language diversity is mentioned once in the chapter about mathematics and then only as something the PTs should learn to take into consideration. In the new *National Guidelines* (Universities Norway, 2016), the resource aspect is added: “the students’ different needs, where cultural, linguistic and social backgrounds must both be taken into consideration and seen as a resource in the teaching” (p. 23). Our study is situated in this change, as we re-focus our teacher education to incorporate the view that all students’ languages can be a resource in the learning and teaching of mathematics. Through a four years long research project *Learning about teaching Argumentation for Critical mathematics Education in Multilingual classrooms [LATACME]*, our research group aims to develop both tools for teaching and theories about this development through an educational design research program. The aim in this paper is to identify our starting point, namely, how preservice teachers are currently aware of, and interpret, multilingual diversity in mathematics teaching and learning as resource, which will be the basis for subsequent interventions.

Internationally we find few studies on how teacher education can develop understandings of language diversity in mathematics classrooms. For instance, McLeman, Fernandes and McNulty’s (2012) study from the USA revealed that issues about mathematics education of English learners needed to have more prominence and to be integrated into teacher education to hinder the development of a deficit perspective among PTs. They explicitly suggested that PTs would need to be provided with experiences within the context of mathematics to help them better understand the interconnection between language and mathematics.

Based on three different contexts (South Africa, Malawi, and Spain/Catalonia), Essien, Chitera and Planas (2016) found that even though the mathematics teacher educators are aware of the linguistically diverse contexts, the “teacher education institutions rarely attend to the complexity of teaching mathematics to linguistically diverse mathematics student teachers in a structured way in their programs” (p. 107). Yet even when there is such awareness, it is challenging to change discourses (Eikset & Meaney, 2018). In their analysis of their conversations about preparing PTs for teaching in multilingual classrooms, Eikset and Meaney

found that other competing discourses, such as the PTs' expressed needs for learning more mathematics, gained priority.

The data for this paper is collected from a mandatory group assignment in the first compulsory mathematics course for those who will become teachers in Grades 1-7. The PTs were asked to write 8-10 pages about number sense connected to children's language and to link this to theory and experiences from their practicum. As part of the process, they had supervision with the second author. The PTs had to include a research question and transcriptions of dialogues between themselves and students. These PTs were in language diverse classrooms, and their interpretation of teaching in the multilingual classroom became an important part of their text. The PTs were encouraged to use their own home language as resource in their problem solving during their teacher education program and were aware of the concept of language as resource. Consequently, our research question is: *How do PT express their awareness and understanding of the construct "language as resource" through written dialogues and reflections?*

## **Theoretical framework**

Planas (2018) described "language as a resource" in mathematics education research as being used more as a metaphor than as a defined concept in the last decade. She demonstrated that "language as resource is not about the unproblematic functioning of language as producer of meaning taken as mathematical and shared" (p. 226). From her perspective, language contributes to the realization of normative meaning in the culture of schooling and school mathematics and does so by reproducing discourses connected to these cultures. In addition, knowledge of language enables learners to influence the process of gaining meaning through interaction. Therefore, language can be a resource both for meaning making and for the relocation of culture in learning situations in mathematics classrooms. From this perspective, mathematical language cannot be separated from the learning gained from other languages or be given priority. Instead, there is a need for language from different contexts, both in and out of school, to be combined in meaning production. In Bakhtin's dialogism, learning can occur in the tension between different forces (Bakhtin, 1981). Tension can occur between voices where different opinions, understanding and linguistics settings are expressed. For example, demands to use the correct language can be one force, while focus on solving a mathematical problem can be another. Tensions might occur in the mathematics classroom between the stratified and formal mathematical language and the language of instruction on one side and the more informal and diverse multivoicedness on the other side (see for example Barwell, 2018; Planas, 2018). However, tensions provide opportunities to negotiate meaning and in multilingual classrooms to learn both language and mathematics.

In their investigations of what happens in classrooms, both Barwell and Planas have focused on translanguaging. Barwell (2018) emphasized the view of students and teachers as languaging, where they use "a repertoire of language practices that draws on students' varied experiences of communication in multiple contexts to make meaning in mathematics" (p. 161), whereas Planas (2018) stated, "translanguaging refers to what people actually do with language to convey meaning" (p. 218). This is a change of focus, from the language systems and the mix between them, to what students and teachers do with language. This includes the use of different representations and mathematical signs to make sense and convey meaning.

## Methodology

The data was collected during the autumn of 2017 when groups of PTs completed a written assignment about mathematics, in particular number sense, connected to children's language, conceptual knowledge and representations in mathematics. The PTs were in their second year of a course to become teachers of Grades 1-7 and were in their first of two semesters of mathematics education. During this semester, teaching mathematics in a multilingual classroom was one of several topics. In their assignment, they were asked to take into consideration how they could adapt their teaching. Two groups chose to include language diversity as an issue in their assignment, and one of these will be analysed in this paper. It was mandatory for the PTs to obtain data that included oral responses from students, where the PTs' role was not to evaluate or judge their students. They were asked not to collect any personal data about the students. The assessment was completed before the PTs received a written request about whether this material could be analysed for research purposes. The dialogues presented in the group's assignment were between a PT and a student in grade 6 in a classroom setting (18 students). The PTs had given the students some tasks, provided them with individual help and in some cases asked the students to explain their thinking.

We analyse two excerpts containing dialogues between a PT and a multilingual, primary-school student and the PTs' reflections on the dialogues and their comments about language and multilingual students. We use a two-layered analysis. First, we sought to identify what PTs and students did to convey meaning, how they used languages, and which repertoire they used, in order to identify instances of translanguaging. Second, we sought to identify language as a resource or as a problem in PTs reflections. To do this, we searched for tensions between voices and the potential for learning that they can create (Planas, 2018; Barwell, 2018).

The original dialogues were in Norwegian and have been translated into English as faithful as we could to retain the original sense. Where the PTs have transcribed incorrect words that the student used, we place the word [incorrect Norwegian] in brackets.

## Result and discussions

The PTs' aim in the activity was for the students to discover the connection between multiplication and division. Although this was the headline on the student work sheet, the PTs claimed that the student, Laban, whose home language is not Norwegian, did not read it. The task was  $98/7=$

PT: Can you explain for us how you were thinking here?

Laban: Here I took 7, but the 9 is bigger. We minus [minuse] only with the nine, nine minus 7 is 2. Then we take the eight and wait... 14... so we took only 1 here (points to the second digit for tens) with 2 which is 28, then we take 7 up to 28 so that is 4, so that is 28 minus 28, which is zero. You should all the time, when it's 7 just you should just insert 1 up here, then it becomes 7 and if you take up till 9. Then it's 14, it can't be that, so we just take 7 times 9 then minusing [minuse] the 9. I can do it all in my headed [hoden].

PT: Oh yeah! That is so cool, have you worked a lot with the timetable [gangetabell] before?

Laban: No, division.

PT: That is sort of times, multiplication. It's kind of, the twin of division.

Together with his written solution, Laban managed to explain to the PT how he was thinking. Laban demonstrated that he saw the connection between multiplication and division when, for instance, he said “which is 28 then we take 7 up to 28 so that is 4 so that is 28 minus 28 which is zero”. He was switching constantly between multiplying up (7 up to 28) and reversing by subtracting so he could check if there would have been zero left to divide.

In the PT's response to Laban's explanation, s/he amplified Laban's explanation by exclaiming “Oh yeah! That is so cool”. The PT also asked Laban if he had worked a lot with times tables (gangetabell) which is an informal word for the multiplication table in Norwegian. Laban denied this by saying, “No, division”. His “No, division” is an interesting change as division is a more formal expression, even if the PT uses an informal expression “times” (gange) instead of multiplication. The PT then followed up with “that is sort of times” before s/he changed the wording to “multiplication”, “It's kind of, the twin of division”. The introduction of “multiplication” as “the twin of division” seems to be a new language construction, perhaps to support Laban to be more aware of the connection between multiplication and division, even though he already demonstrated this in his explanation. As the student and PT used resources from their informal and formal language to make meaning together, they were languaging (Barwell, 2018). The student's idiosyncratic language of “minuse” (subtract), and his conjugation of a noun into a verb as in “headed” (hoden) was in the transcription in the group assignment. However, the PTs did not highlight these examples. In this case the tension in language use was apparent in the juggling between formal and informal mathematical language, rather than between a home language and the language of instruction.

When Laban explained and requested time to think, indicated by his “wait”, he used informal words and sentence construction. While he was answering the PT's question, he began to use formal mathematical words, such as division, which belong to the school mathematical vocabulary. The dialogue between PT and Laban is characterized as a mutual willingness to make sense together. It seems that the student affected the language choices of the PT.

The group of PTs reflected on the dialog in their assignment:

He explained his way of thinking and led us through his calculations. This gave us the impression that it was not his number sense that was the challenge for Laban. He is a student we can clearly see has gained much practice in mathematics.

By mentioning that Laban explained his thinking and led them through his calculation, they recognized his skills to communicate and his number sense. However, they indicated that there was still something which was a challenge for Laban, without specifying what this was. By including his language errors, one interpretation is that the PTs saw language as a problem even as they recognized his communication skills. In the summary, the PTs repeated their belief in Laban's and another multilingual student's number sense and their explanation skills:

The students could also explain their way of thinking, the different types of calculations and how they could use this in their daily lives without much difficulty. ... Thus, we will say that it is not the numerical understanding or the number concept that hinders the students from dealing with mathematics, but rather that it is insufficient understanding of the concepts.

By stating that the students can “explain their way of thinking” and that “numerical understanding or number concept” is not the problem, they recognized the skills the students had, and implicitly that the students were able to use language in Norwegian as a resource to make others understand their thinking. However, they also mentioned what hinders the students from “dealing with mathematics”; the multilingual students had “insufficient understanding of concepts”. In this way they saw the student in a deficit perspective and the lack of concepts in Norwegian as a problem.

As an example of the problem that a multilingual child had with understanding mathematical concepts, they included this conversation with another multilingual student, Ahmed:

- Ahmed:       What is “even” [jevent] I don’t understand...
- PT:            You play soccer Ahmed, don’t you?
- Ahmed:       Yes, Tuesday and Thursday
- P.T:           Then you divide into two teams and play against each other, don’t you?
- Ahmed:       Yes!
- PT:            When you divide into teams, what is important?
- Ahmed:       That it’s fair. That there are equally many on each team.
- PT:            YES! That is another way of explaining “even”.

The PT used an example from a familiar situation for Ahmed, soccer, to explain what “even” means in mathematics. By using language repertoires that they had in common from outside of school mathematics, they had made sense and gained a shared understanding of the mathematical concept. In their assignment, they explained how they used the example of soccer as a translational link to help the student understand the concept of “even”. The PTs used the conversation as an example of where language can cause a problem, as they write “the student does not have an understanding of Norwegian term for the concept of even”. At the same time, they demonstrated how they used language as a resource in the dialogue by drawing on the example from soccer as translation link. They used repertoires from different contexts, formal and informal school mathematics, and out of school activities as soccer, to make sense together.

A question arises about whether the students’ and PTs’ use of languages from different situations, can be considered translinguaging (Planas, 2018). In the Norwegian context, it was repertoire from formal and informal Norwegian which were being transformed as meaning is being made. The PTs’ understanding of language in multilingual classrooms also reflected a tension between how they made use of theirs and the students’ language resources from different contexts, and seeing their student from a deficit perspective where language is a problem:

During the practicum, we learned that there is a connection between being able to master mathematics and to master the language. Minority-speaking students may have limited vocabulary and little understanding of Norwegian terms. This may be because the student speaks little Norwegian at home, in his immediate social environment, or never experiences situations where the terms are used.

The PTs recognized the connection between language and mathematics learning. It is clear from their perspective, that it could be a disadvantage for a student to not have Norwegian as their home language, which could cause limited understanding of Norwegian terms. The PTs only mentioned the Norwegian language. The home language and mathematical concepts that the students may have in this language were not discussed. There was no evidence that the PTs saw the students using their home languages in mathematics. This suggests that it may be difficult for PTs to know how to use the students' language and cultural background as resource and this pedagogical practice remains more an idea than an experienced reality in primary schools.

### **Concluding remarks**

In this study, we identify tensions in more than one sense. There is a tension between “language as resource” captured in the transcribed dialogues and “language as problem” in the PTs' reflections. This tension could provide opportunities for learning if this tension become topics for discussion. In addition, we find a tension between students' and PTs' language use with informal and formal mathematical terms. Together they were languaging by using experiences of communication in multiple contexts to make meaning (Barwell, 2018, p. 161), as when they used soccer to explain even, and in the PTs' effort to connect concepts, when making the new language construction, multiplication as “twin to division”.

Planas' (2018) conceptualisation of language as resource has given us the opportunity to see how PTs use a repertoire from different contexts in their meaning making. The opposite metaphor, language as problem, made us aware of where PTs see language diversity in the mathematics classroom as a problem and how the students' home languages are neglected.

If language as resource, which includes transanguaging, is going to be valuable in PTs' teaching in the future, they need to be exposed to broader understandings about multilingual teaching both in teacher education and in the practicum, as McLeman, et al. (2012) suggested. How can different languages be present in Norwegian schools where there can be so many different languages in one classroom and when the “Norwegian only” discourse is so strong? There is a need to develop a common understanding of what language as resource can be together with the teachers in the schools where students do their practicums. As the PTs' dialogues demonstrated, repertoires from different contexts, informal and formal, and the students' culture, such as soccer, can be resources in teachers' mathematical dialogues with students. Identifying these potential resources in shared repertoires of experience can be developed further to include students' home language. Teacher educators need to engage in open discussions with PTs about which discourses dominate and which discourses should be developed to avoid language being viewed from a deficit perspective. Our next step is to develop an intervention in which practicum teachers, PTs and teacher educators explicitly

discuss tensions between language as resource and language as problem. Working together to change our discourses may help us to explore how different languages can be present.

# Sense and reference of signifiers for elements of polygons

Frode Rønning and Heidi Strømskag

Norwegian University of Science and Technology, Trondheim, Norway;

[frode.ronning@ntnu.no](mailto:frode.ronning@ntnu.no) [heidi.stromskag@ntnu.no](mailto:heidi.stromskag@ntnu.no)

*This paper is based mainly on a planning meeting involving teachers and researchers before classroom sessions in a Norwegian school where 7-8-year-old children are working with concepts connected to geometrical shapes. During the planning meeting different conjectures were made about possible confusion that might occur concerning the names of the parts (elements) of a polygon (edges and vertices). Comparing these conjectures to what actually happened in the classroom, it turns out that the group of experienced teachers and teacher educators were not able to foresee all the nuances in the children's sense and reference concerning concepts connected to polygons. The findings suggest that these concepts may be more challenging than previously assumed. The classroom sessions are designed using principles from Brousseau's Theory of didactical situations (TDS).*

*Keywords: Register, sense and reference, polygons, milieu.*

## Introduction

The project Language Use and Development in the Mathematics Classroom (LaUDiM) is an intervention study carried out in collaboration between researchers at the Norwegian University of Science and Technology and two local primary schools in the period 2014-2018. A central part of the project is to design and implement teaching sequences. The design process takes place in close collaboration between researchers and teachers. The teachers are responsible for the implementation in their respective classes, with researchers present in the classroom. The core of the project is twofold: to study pupils' development and use of mathematical language to express their ideas, and their use of language in arguing and justification; as well as to study and develop teachers' mathematics teaching practices. The design of each teaching sequence is guided by principles from *The theory of didactical situations, TDS* (Brousseau, 1997). A teaching sequence typically consists of a planning meeting between teachers and researchers followed by two or three classroom sessions. Between the classroom sessions there are reflection sessions to discuss what happened in the classroom and, if necessary, revise the plans.

This paper is mainly based on data from the planning meeting preceding one particular sequence of teaching sessions where the main aim is pupils' development of a precise mathematical language for describing elements and properties of polygons. The actual classroom sessions were reported on in (Rønning & Strømskag, 2017). In the present paper, some of the findings from the first classroom session are mentioned in order to be able to reflect on what happened in the planning meeting. Also the reflection session after the first classroom session will be mentioned. The paper will shed light on the importance of the planning session and how different discourses influence the planning, as well as deepen the knowledge about the complexity regarding the, apparently simple, concepts involved. We will in particular compare teachers and researchers' conjectures about pupils' language use about polygons to what actually happened in the classroom.

## Theoretical framework

In this paper we see a word as a sign, or signifier, and, in the language of Frege (1892) we connect the sign with its *Sinn* and its *Bedeutung*. The German words *Sinn* and *Bedeutung* can be seen translated into English in different ways. We shall follow the translation in (Geach & Black, 1960), using the words *sense* and *reference*, respectively. Here, the reference is the object that the sign refers to and the sense comprises all thoughts and ideas connected to the sign. In his work, Frege gives examples to show that two different signs may have the same reference but different sense. One example used by Frege is the following, from Euclidian geometry. Let  $a$ ,  $b$  and  $c$  be the medians of a Euclidian triangle. Let  $A$  be the intersection point between  $a$  and  $b$ , and  $B$  be the intersection point between  $b$  and  $c$ . Then  $A$  and  $B$  have different sense but from a theorem in Euclidian geometry the points  $A$  and  $B$  coincide, so  $A$  and  $B$  have the same reference (see e.g., Geach & Black, 1960, p. 57).

A distinction similar to Frege's sense vs. reference is made by Peirce in his definition of a sign: "A sign is a thing which serves to convey knowledge of some other thing, which it is said to *stand for* or *represent*. This thing is called the *object* of the sign; the idea in the mind that the sign excites, which is a mental sign of the same object, is called the *interpretant* of the sign" (Peirce, 1998, p. 13). Also Ogden and Richards (1923/1948) describe a similar model when they talk about a *symbol* as being connected to a *referent* via a *thought* or *reference*. They state that "[b]etween the *symbol* and the *referent* there is no relevant relation other than the indirect one, which consists in its being used by someone to stand for a referent" (p. 11). They further state that "[a] true symbol = one which correctly records an adequate reference. ... [W]hen it will cause a similar reference to occur in a suitable interpreter" (p. 102). A given word is therefore a true symbol if it causes the same reference in different interpreters. Successful communication in a mathematics classroom depends on symbols causing the same reference in the actors involved, usually teachers and pupils.

Halliday (1979) defines the term register as "a set of meanings that is appropriate to a particular function of language, together with the words and structures which express these meanings" (p. 195). So, changing between registers can mean that the same word gets both a different sense and a different reference. The mathematical register is characterised by the property that words have very precise sense and reference. Sometimes the same word may be used both in the mathematical register and in the register of everyday language but with different sense and reference. This feature is language specific so that for a given word it can be part of both the mathematical and the everyday register in one language but translating into another language may lead to different words in different registers. When the same word is used in both the mathematical and the everyday register in a language, it is of particular importance to be aware of possible discrepancies in sense and reference because such a word may not be seen as a challenge in the learning process.

## Design and research question

Each teaching sequence in the project starts with a planning meeting where teachers and researchers work together to plan the activities for two or, in this case three, classroom sessions. In this planning meeting TDS plays an important role. TDS provides a model for instructional design, where a didactical situation is designed with a problem that has the target piece of knowledge as an optimal solution (Brousseau, 1997). The didactical situation consists of four phases—action, formulation,

validation, and institutionalisation—designed with milieus so as to make the knowledge (necessary to solve the given problem) progress from informal knowledge to increasingly formal (mathematical) knowledge. More precisely, in action, the pupils use an *implicit strategy* to solve the problem given to them; in formulation, they need an *explicit strategy* because they are supposed to use the knowledge to make another pupil solve the problem; in validation, the knowledge needs to be *mathematical knowledge* in order to justify that the solution is valid in general; and, in institutionalisation, the teacher decontextualises the knowledge reached to become *scholarly knowledge*. For a more detailed account, and exemplification, of the evolution of knowledge and the teacher's role in the different phases, see (Strømskag, 2017).

A teaching sequence was designed according to the teachers' and researchers' expectations regarding pupils' sense and reference of words connected to polygons (see Rønning & Strømskag, 2017). However, the data collected during implementation of the sequence gave us insight into the pupils' *actual* sense and reference of the words in question. This design was instrumental for creating opportunities for revealing the challenges of the learning process. For this paper however, the concepts from Brousseau's theory will not play a significant role.

Between the first and the second classroom session follows a reflection session, where adjustments are made for the second session. Researchers present in the classroom interact with the pupils but are not directly involved in the teaching. The planning meeting and classroom activities are video recorded, and the reflection meeting is audio recorded. After completing a cycle of planning, reflection and classroom sessions, teachers and researchers meet to watch parts of the video recordings from the classroom. This is also video recorded, but is not used as data for this paper.

The topic of polygons turned out to be interesting for several reasons. It demonstrated how the phenomenon that words (signs) may have different reference in the mathematical and everyday registers constrained pupils' conceptual development and although parts of this phenomenon could be foreseen in the planning meeting, unexpected observations were made, showing that there are challenges involved in the apparently simple concepts involved when talking about polygons.

This paper is addressing the following research question: *To what extent do teachers' and researchers' expectations regarding pupils' sense and reference of words connected to polygons fit with actual experiences from the classroom?*

The main data are the transcribed video recordings from the planning meeting. In a line by line analysis of the transcription, we look for evidence of contributions from the different participants in the meeting. Then these contributions are compared to what actually happened in the classroom at one of the schools. Here we will refer to findings in (Rønning & Strømskag, 2017).

## **The Norwegian language and the mathematical terms involved**

The relevance of the work with the topic of polygons is connected to particular features of the Norwegian language. In Norwegian, polygons are named after the number of edges, using ordinary number words. That is, an "*n-gon*" is called an "*n-edge*", where *n* can be three, four, .... The Norwegian word for *edge* is *kant*. For  $n \geq 5$  this is in line with English, except that the English words are based in Greek (e.g. pentagon), and therefore they have no obvious meaning for young children.

In the paper, we will use the Norwegian word *kant* (plural *kanter*) and whenever this word occurs, it is written in italics. In everyday language, the word is used in expressions like “falling off the *kant* of the cliff”, “walking along the *kant* of the road”, “sitting on the *kant* of the table”. *Edge* is also a word in English everyday language but *vertex* is a mathematical term, not used in everyday language. The Norwegian language does not have a strictly mathematical term for vertex. The word *hjørne* is used (*corner* in English). In the sequel, we will use *hjørne* (plural *hjørner*), written in italics. Since the names for the figures are made up of everyday terms, it is generally believed that learning the names of and distinguishing between different polygons is an easy task. In German, the situation is very much like in Norwegian, except there the focus is not on the edges but on the vertices, i.e. a *firkant* (four edge) is referred to as a *Viereck*, meaning “four corner”. Since the number of edges is equal to the number of vertices ( $V = E$ ) it does not matter whether the edges or the corners are referred to, the number word connected to the figure will be the same.

Another feature is that the edges may be referred to by different words depending on the situation. For instance, when stating the formula for the area of a square, it is often said “*side* times *side*”. Then the word “*side*” (or “*sidekant*”) is seen as a variable denoting the length of the line segment making up the edge. The word *side* corresponds to the English word ‘side’.

## The planning meeting

A starting point for the discussion is that the participants (teachers and reseachers) present their experiences with the topic and also some evidence of confusion regarding language. Present at the planning meeting were the teachers Ruth and Pam, and the researchers Anne, Becky and Cathy.

- Ruth: We mostly talk about *kanter* so far. There is not so much talking about *hjørner*.
- Anne.: Or they do not agree on what a *kant* really is. Is this the *kant* (strikes along the side of the table), or is this the *kant* (marks the transition between the table top and the side).
- Ruth: We have discussed this a little in the staff room. Is it *side* or is it *kant*? Because when you talk about the area of a square, for instance, then it is like *side* times *side*, and why is it then called *side* when it is called *trekant* [triangle] and *firkant* [quadrilateral] and how many *kanter* has a ... ? But when you come to three dimensional figures, then the *kant* is in a way, when you see from one side, then it is one of the sides.
- Pam: *Sidekant* I think it is called.
- Ruth: Yes, because you also have the concept *sideflate* [face], and that is on a three-dimensional figure. And that is the *side*, that is what we call the *side*. So, I think it is best that the line in a two-dimensional figure is called a *kant*.

Ruth has observed that the same object in a geometric figure may be given different names in different contexts. When talking about the line segments making up a polygon, the word *kant* is used but when the length of the line segment is referred to, e.g. for calculating the area of a square, the word *side* is used, as in the formula *side* times *side*. This indicates that the words *kant* and *side* have different sense, although they refer to the same element of the polygon, i.e. they have the same reference. It could be argued that in the formula *side* times *side* the reference is not the actual line segment itself,

but a number representing the length of the line segment. In the beginning, Ruth also admits that they have not talked so much about *hjørner*, mostly about *kanter*. This may be because it is the word *kant* that appears in the names of the polygons. Ruth also refers to the three-dimensional situation where the word *sideflate* is used for the face (*F*) but also sometimes just *side*, for short. She finds this confusing and suggests to stick to the word *kant*.

- Anne: A *hjørne* is where two *kanter* meet.  
 Becky: Yes, so then at least we agree.  
 Ruth: This is a much simpler definition.  
 Anne: Yes, but it isn't. When we discuss this with student teachers, they do not agree on what a *kant* is. Some envisage, yes, a *trekant*, it has three *kanter*, yes, what I would call *kanter*, and like you Pam, call *sidekanter*, but it also has three *hjørner*. So if you say *trekant* and think about *hjørner*, there is no mismatch.  
 Pam: And I heard a mother asking, when we had about *hjørner* and *kanter* on the working plan; *hjørner* AND *kanter*, but isn't that the same? That is the same, so why?  
 Cathy: I have not at all thought like this. I have thought like you, a *hjørne* is a *hjørne*.  
 Pam: Yes, and that is correct. But I think many have a wrong opinion about this.

Anne gives a precise mathematical definition of the term *hjørne*, and both Becky and Ruth seem to be happy about this, recognising it as a simple definition. However, Anne claims that it may not be that simple because she has evidence from student teachers not agreeing on what a *kant* actually is. They say *kant* and mean *hjørne*, and because of the relation  $V = E$  for polygons they get away with it. This is supported by Pam who has evidence from a mother of one of the pupils claiming that *hjørne* and *kant* are two words for the same thing. Cathy has not reflected on this being an issue. This conversation shows evidence that the word *kant* may be used by different people with different sense and different reference and also that some people think that the two words are two different signs with both the same sense and reference. The fact that the group discussing this is a group consisting of experienced teachers and teacher educators indicates that the topic may not be as simple as it may seem at a first glance.

There is agreement that one should stick to the concepts *kant* and *hjørne*, and that it is important to stick to one word in the beginning, and Ruth says that *kant* seems to be the most precise word.

## The reflection session

The reflection session is based on experiences from the first classroom session and took place immediately after the classroom session. The classroom session is discussed in (Rønning & Strømskag, 2017). These are some of the observations made:

- Most pupils used the word *kanter* to refer to the vertices but there were also some who used it correctly, to refer to the edges.
- Some pupils refer to a vertex as a *hjørne* when they approach it from the inside and as a *kant* when they approach it from the outside.
- In a quadrilateral with one reflex angle and three acute angles, the vertex at the reflex angle is sometimes referred to as a *hjørne* and a vertex at an acute angle is referred to as a *kant*.

The classroom session revealed that for most of the pupils the sense of the word *kant* was something sharp. This was emphasised when they talked about *kanter* as “the pointed parts [spissene]”. The word *hjørne* was not often in use but when used, it had the sense of a space, something one can stay in, corresponding to the expression “stand in the corner” [stå i hjørnet]. It can therefore be said that the pupils use two different words for the same reference but each word has its own sense which is connected to the size of the angle at the vertex, or whether they see the vertex from the inside or from the outside.

Pam was surprised that they did not use the words correctly. They mainly used the word *kant* with the reference expected of the word *hjørne* and paid very little attention to the actual *kanter*, i.e. the edges. Diana, a researcher who was not present at the planning meeting, suggests to use *sidekant* about what they call *strek* [line]. Then there is a discussion about how the words *kant* and *hjørne* could be connected to everyday settings. Diana had observed in the classroom that some pupils talked about a “soft *kant*”, and said that that is a *hjørne* (with reference to a part of a local shopping centre), but a “real *kant*” is sharp. For 3D objects it makes sense to talk about an edge (*kant*) as being sharp. This may transfer to 2D objects. One of the tasks for the pupils was that they should write the name of a given geometrical figure and explain why it had this name. Based on the pupils’ workings it seemed that they used the words in a correct way. They could draw e.g. a quadrilateral and write “this is a *firkant* because it has four *kanter*”. Here the reference of the word *firkant* is the drawing of a quadrilateral, as it should be, and the sense of the word is that the figure has four *kanter*. This is also correct, and the written statement will not reveal the misconceptions.

In the reflection session, it is discussed how the activity could be developed to overcome the misconception. In the first classroom session, it turned out that using the abstract geometrical figures as reference context was inadequate to stimulate the correct concepts connected to the words *kant* and *hjørne*. Therefore, the teacher suggested to use a mini-pitch as a reference context. This was assumed to be a context from the pupils’ everyday experience and at the same time a context with properties sufficiently similar to an abstract geometrical figure, in this case a rectangle. Then the idea was presented to take the pupils out into the mini-pitch in the school yard and give commands like “go to the *hjørne*”, “walk along the *kant*” and similar expressions.

## Discussion

The target knowledge of the teaching sequence was that the pupils should develop the scientific language for naming 2D shapes and become aware that these names are based on the number of edges (*kanter*) in the shape. To know the difference between edges (*kanter*) and corners/vertices (*hjørner*) will then also be part of the target knowledge.

The planning session revealed certain conjectures about the use of the words *kant* and *hjørne*. The different participants in the session had different expectations, based on different experiences. The teachers had experienced confusion based on previous work with pupils and also based on conversations with parents. Teacher educators in mathematics had experienced confusion among student teachers, whereas the general educators were not necessarily aware that these words could be a source of confusion. For most adults, at least adults with some mathematical background, it is so obvious what is a *hjørne* and what is a *kant* that they do not envisage any problems with this. And

also, the connection  $V = E$ , ensures that the naming of geometrical figures will be consistent even if there is confusion about what is what. But when the sign is broken down into components, *tre* = three and *kanter* = edges, we see that the sense and reference are not as desired.

<i>Kant</i>	Sense	Reference
Mathematical discourse	A straight line segment	E.g. <i>AB</i> , <i>BC</i> , <i>CD</i> and <i>AD</i> in quadrilateral <i>ABCD</i> .
Pupils' discourse	Something sharp A real <i>kant</i> is sharp The pointed parts	E.g. <i>A</i> , <i>B</i> , <i>C</i> and <i>D</i> in a convex quadrilateral <i>ABCD</i> , when seen from the outside.

**Table 1: Sense and reference of *kant***

<i>Hjørne</i>	Sense	Reference
Mathematical discourse	A point where two <i>kanter</i> meet	E.g. <i>A</i> , <i>B</i> , <i>C</i> and <i>D</i> in quadrilateral <i>ABCD</i> .
Pupils' discourse	A spacious area A soft <i>kant</i>	E.g. <i>A</i> , <i>B</i> , <i>C</i> and <i>D</i> in a convex quadrilateral <i>ABCD</i> , when seen from the inside. A non-convex vertex.

**Table 2: Sense and reference of *hjørne***

Even if some confusion was expected, the classroom sessions brought new knowledge to the sense and reference of the words *kant* and *hjørne*. This means that even for such seemingly simple mathematical concepts as here, the group of experienced teachers and teacher educators could not fully forecast how the terms would be handled by the pupils. Using the terms from Ogden and Richards (1923/1948) we may say that the words *kant* and *hjørne* did not function as true symbols because they did not cause the same reference in all persons involved.

The insight we got during the classroom sessions was used to redesign the didactical situation with respect to the conventional sense and reference of the words *kant* and *hjørne*. The desired statuses of knowledge in formulation and validation, as described above, were decisive for the team in designing a material milieu and a game (for acting on the milieu) with didactical potential regarding the target knowledge, so the pupils could know whether their responses were adequate or not. The new material milieu is shown in Figure 1. It consists of 12 tiles, where on one side of the tile was depicted a polygon where the edges had one colour and the vertices were marked with another colour. On the reverse of the tile was written descriptions like e.g. “*firkant* (quadrilateral) with blue *sidekanter*”. This game was played in pairs of pupils both having the full set of tiles. One pupil reads the text and the other one is supposed to pick the correct shape. After picking he/she can turn the tile and read the text to see if the correct shape has been picked.

The conditions described in this paper indicate that there is a need to address the concepts *hjørne* and *kant* in Norwegian schools. The naming of figures by counting the *kanter* using ordinary Norwegian number words, like in *firkant*, may indicate that there is no need to go further into the topic. Also, the books that are used for the pupils seem to take the concepts for granted, there is never any indication of what is actually *hjørne* and what is *kant*. The discussion in the planning session also shows that

there is varying consciousness about the topic among teachers and researchers. And those that are conscious about it are so because they have previous experiences indicating that there may be some confusion.

Distinguishing between edges and vertices can also be seen to be important for future learning, e.g. about polyhedra, where the number of edges and the number of vertices are not the same.

# Abstract thinking and bilingualism: Impact on learning mathematics

Leila Salekhova<sup>1</sup> and Nail Tuktamishov<sup>2</sup>

<sup>1</sup>Kazan Federal University, Russia; salekhova2009@gmail.com

*Studies on the impact of bilingualism on academic performance in mathematics generally focus on potential problems faced by bilingual students rather than potentials and opportunities. The current research took an alternative approach and explored whether learning advantages for bilinguals may reveal themselves in solving difficult mathematical tasks that require abstract reasoning. Sixty-two bilingual and monolingual first-year students of Kazan Federal University participated in the experiment. No differences were found between bilingual and monolingual samples in solving easy and medium mathematical tasks; however, an advantage on the side of the bilingual students was observed with some of the most difficult tasks. The results from this study therefore show that bilingualism may be related to abstract thinking abilities and mathematics learning.*

*Keywords: Abstract thinking, learning mathematics, bilingualism.*

## Abstract thinking and bilingualism

Abstract thinking is a type of cognitive activity when a person moves away from specific details and begins to reason in general, using concepts, judgments and conclusions, among other structures. Moreover, abstract thinking allows us to find new things and create something new, to deviate from the rules and dogmas and to consider the phenomenon or process from different sides. The formation and development of the pupil's abstract thinking - the ability to use symbolic representation or logic – is an actual task of mathematical education.

There are many kinds of research on the relationship between mathematics and bilingualism, but only a few papers, which suggest that bilingualism may improve a person's ability to engage in more abstract or symbolic thinking processes. For example, in her work Planas (2014) argues that bilingualism can actually create opportunities for learners to deal more deeply with mathematical concepts. She observed a small sample of Catalan language learners interacting with dominant Catalan speakers while solving algebra problems in groups. The Catalan language learners used different problem-solving strategies (e.g., using a geometric approach to understand an algebraic expression) to overcome the lack of specific mathematical terminology in the academic language of instruction. The Catalan language learners also focused more on the meaning of mathematical terms than dominant Catalan speakers did because they were unfamiliar with the required terminology.

In recent years, more and more research studies have focused on the potential cognitive benefits of bilingualism. Several studies confirm that the experience of using more than one language can create unique opportunities in the bilingual brain, leading to cognitive benefits for bilinguals (Adesope, Lavin, Thomson, & Ungerleider, 2010). However, the exact nature of these benefits has proved difficult to determine in relation to specific subject contents.

On the other hand, the bilingual experience may provide other cognitive benefits. A number of researchers have supported the hypothesis that the constant switching of bilinguals from one language

to another leads to an increase in executive functions (Bialystok, Craik, & Luk, 2012). Other scientists have not found any advantages for bilinguals over monolinguals in executive functioning (Paap & Greenberg, 2013). Cummins (1991) have shown that bilinguals can learn new rules more effectively than monolinguals and have an advantage in meta-linguistic awareness.

Specific research by Gentner and Goldin-Meadow (2003) confirms that knowledge representation depends on the language of instruction; hence, there may be negative consequences when knowledge is transferred from one representative system to another. In other words, negative effects are observed when the languages of learning mathematics and knowledge extraction differ. This was confirmed by Spelke and Tsivkin (2001), Campbell, Davis and Adams (2007), but also in work from our context developed by Salekhova (2016, 2018).

A bilingual student may have problems understanding the essence of a mathematical problem if he or she is not familiar with the terms used, which are associated with abstract mathematical concepts. Conversely, there may be a positive cognitive effect due to multiple transpositions. They arise whenever an abstract concept is used and transferred from one representative system to another, when there are two different language terms in the language repertoire of a person. A number of studies have shown that the linguistic complexity of texts in mathematical achievement tests can negatively affect the performance of bilinguals for whom the language of instruction and the language of testing is not their mother tongue (Haag, Heppt, Stanat, Kuhl, & Pant, 2013). However, it is unclear which specific features of language complexity contribute to this deficiency.

The present study explores whether bilingualism can potentially influence the development of abstract thinking that plays a crucial role in learning mathematics. The study's research question derives from the assumption made by the Russian psychologist Lev Vygotsky (1962). He believed that bilingualism could have positive consequences for the flexibility of human thought. He argued that the ability to express the same thought in different languages allows us to understand the symbolic function of words, to consider words in more abstract, semantic terms and to see that any particular language is only one semiotic system among many. Vygotsky studied issues concerning the relationship between bilingualism and flexibility of thinking following the awareness that bilinguals can be (dis)advantaged in traditional learning environments of Russia at that time.

## **Research context - bilingualism in Russia and Tatarstan**

A large number of ethnic groups living within the boundaries of the Russian Federation is evidence of a complicated history of migrations, wars, and revolutions. In the process of its historical development, Russia has emerged as a multinational, multicultural and multilingual state. About 150 languages are spoken in the territory of Russia. This ethnic diversity has had a strong influence on the state education policy. The Russian Constitution guarantees all ethnic groups the right to maintain their mother tongues. Although Russian is the official language, some ethnic republics have the right to establish their own official languages besides Russian. The use of an ethnic language in education depends on the development of its written forms and literary standards.

Tatarstan is one of the ethnic republics of Russia, and Tatars constitute 53% of its population. There are two official languages – Russian and Tatar in Tatarstan. They are used for teaching almost all school subjects and the choice of the language of instruction depends on the school location (rural or

urban) or the model of bilingual education (immersion, partial immersion, CLIL). Tatar is spoken by most of the people in Tatarstan as either a dominant or a second language. It plays a strong role in the construction of the Tatar cultural identity. Russian–Tatar, and Tatar–Russian bilingualism is widespread in Tatarstan if we consider bilingualism as the ability to speak two languages.

## Experiment and materials

The present experiment sought to address the research question of whether bilinguals would outperform monolinguals on solving difficult symbolic math tasks. Algebra typically represents the students' first encounter with abstract mathematical reasoning and it therefore causes significant difficulties for students. Symbolic abstraction is a significant component of algebraic thinking. Algebra is a fundamental discipline in higher mathematics and plays a major role in the field of STEM education. The transition from arithmetic to algebra is a challenging task for learners, as algebraic thinking requires a shift from calculating exact values to considering relationships between quantities and operations with unknown values and variables.

One of the important topics of algebra is the study of functions, and many researchers favor teaching other algebraic topics, such as the solution of equations and inequalities based on functions. Students usually perceive functions as a tool to get answers but not as a mechanism to express the relationship between variables presented as symbolic abstractions.

Since abstract thinking represents the ability to process information, special symbolic algebraic tasks were developed in order to test for possible bilingual advantages in symbolic abstraction. Images and symbols are often used in abstract thinking, and their meaning derives solely from the thinking process. Algebraic functions are presented in an unconventional form; a new symbol is used to represent a certain sequence of basic mathematical operations. The task in our study has the following form:  $x \propto y = xy + x - y$ . What is  $5 \propto 3$ ? The solution of this task requires an abstract-symbolic approach and the understanding that the new symbol indicates the relationship between the variables and a certain set of mathematical operations (see Table 1).

Sample tasks			
The first task with its solution is given as an example. The answers are provided for the remaining tasks.			
1.	$x \propto y = xy + x - y$	What is $4 \propto 5$ ?	
	Solution: $4 \propto 5 = 4 \times 5 + 4 - 5 = 19$		Answer: 19
2.	$x \text{ } y = x/y + y - 3$	What is $6 \text{ } 2$ ?	Answer: 2
3.	$x \neq y = 7x - 2y$	What is $5 \neq 3$ ?	Answer: 29
4.	$x \alpha y = (3y - 4x) + 5$	What is $1 \alpha 4$ ?	Answer: 13
Easy tasks			
1.	$x @ y = (x - y) + (2x + 3y)$	What is $4 @ 2$ ?	
2.	$x \S y = (xy) (x + y)$	What is $5 \S 3$ ?	
3.	$x \text{ } y = (x + y)^2 / (x - y)$	What is $4 \text{ } 2$ ?	
4.	$x \# y = x^3 - y + 2x + 3y$	What is $1 \# 7$ ?	
Medium tasks			
1.	$x \rightarrow y = (xy) (x + y)$	What is $(4 \rightarrow 2) \rightarrow 3$ ?	
2.	$x \odot y = y^2 + xy$	What is $5 \odot (3 \odot 2)$ ?	

3.	$x \leq y = xy$	$x \geq y = x/y$	What is $(9 \leq 2) \geq 3$ ?
4.	$[x] = x^2 / 2$	$\{y\} = y + 2$	What is $[7] / \{7\}$ ?
<b>Difficult tasks</b>			
1.	$\langle x \rangle = 4x - 2$	$2 - \langle x \rangle = x - 1$	What is $x$ ?
2.	$x ? y = 11x/y$	$z ? 7 = 200$	What is $z$ ?
3.	$x \bullet y = (x - 2y)/y$	$4 \bullet 5 = z \bullet 10$	What is $z$ ?
4.	$(x) = x^2 - x$	$(y) = (y - 2)$	What is $y$ ?

**Table 1: Symbolic mathematical tasks**

Mielicki, Kacinik and Wiley (2017) introduced the types of tasks in Table 1 for school pupils. We modified them to suit our adult participants in the research. The tasks in the current study were designed to test the development of participants' abstract thinking in a way that is intended not to depend on their previous academic experiences dealing with algebraic functions.

## Participants

Sixty-two bilingual and monolingual first-year students of The Institute of Philology and Intercultural Communication of Kazan Federal University (Russia) aged 18 to 20 years participated in this experiment. They perceived this kind of symbolic problems as new because they were not familiar with the concept of binary algebraic operation.

Participants were categorized as early bilinguals ( $N=29$ ) and monolinguals ( $N=33$ ). Bilinguals who have had a prolonged exposure to more than one language before the age of 7 are called early bilinguals. Prolonged exposure is when both parents in the family speak a language other than Russian or when the individual attended a school in which he or she did not study in Russian. We selected only early bilinguals to identify and test positive effects based on previous studies examining the cognitive benefits associated with early bilingualism (Bialystok, Craik, & Luk, 2012). Native speakers of Russian, who did not experience prolonged exposure to another language from early childhood, were considered monolinguals.

The language history of the participants was compiled with the help of interviews. In the sample of bilingual respondents, 57% indicated Tatar as their dominant language. Other dominant languages were Russian (18%), Mari (7%), Udmurt (6%), Bashkir (4%), Tajik (3%), Uzbek (2%), Kazakh (1%), Azerbaijani (1%), and Chinese (1%).

Researchers have tried to measure dominance for many years. Some scientists use such criteria as pronunciation and vocabulary to evaluate a bilingual's languages. Others apply various tests such as naming images, recognizing words, executing a command, or translating sentences from one language to another. Based on these, the experts rate the dominant language of the participant. However, these different approaches are criticized for primitivism in the analysis of language knowledge and bilingual behavior, as the two languages are evaluated independently. We preferred an approach in which bilinguals themselves assess their level of bilingualism. We defined the dominant language as one in which the bilingual has reached an overall higher level of proficiency at a given age, and/or the language used more frequently, and in a wider range of domains.

Bilingual participants were asked to describe their level of proficiency in the dominant and the second language on a scale of 0 to 10 (0=no, 10=perfect) for “speech activity” and “understanding”. Bilinguals reported similar levels of proficiency in the dominant language ( $M=8.36$ ;  $SD=1.48$ ) and in the second language ( $M=8.49$ ;  $SD=1.24$ ) for “speech activity”. Similar levels were reported in the dominant ( $M=8.66$ ;  $SD=1.34$ ) and second languages ( $M=8.88$ ;  $SD=1.03$ ) for “understanding”.

Russian was the dominant language of all the monolinguals. The average age of onset for second language acquisition was 7.13 ( $SD=1.53$ ). Unlike bilinguals, monolinguals reported a higher level of proficiency in speaking Russian ( $M=9.61$ ;  $SD=0.93$ ), and a lower level in their second language ( $M=2.23$ ;  $SD=1.16$ ). Monolingual participants also described their level of understanding in Russian ( $M=9.65$ ;  $SD=0.76$ ) as higher than their second language ( $M=2.97$ ;  $SD=1.57$ ).

## Procedures and results

Subsequently, the participants were offered to solve symbolic mathematical tasks (see Table 1): four types of symbolic math tasks of increasing complexity, consisting of four items. The solution to the first problem in each variant was given as an example. After completing each of the remaining three tasks, participants were informed whether they had answered correctly or incorrectly. Then the participants solved 12 more tasks of three levels of difficulty (easy, medium and difficult). The level of difficulty was determined by the number of new characters in the problem, as well as the number of operations required to solve the problem.

The tasks were presented in increasing complexity, and all participants performed the same tasks in the same sequence. Tasks were shown on the computer screen; the participants recorded the answers on a special worksheet. They were asked to make as many transformations and calculations as possible mentally but also had a pencil and paper, which they could use if necessary. Participants performed the tasks at their own pace and received one point for each correct answer.

Figure 1 shows the distribution of the number of correctly solved symbolic math tasks at each level of complexity by monolinguals and bilinguals. It signals minor differences between bilinguals and monolinguals in favor of the latter in solving easy and medium level problems. However, significant differences emerge in the other sense in solving symbolic math tasks of high complexity.

**Figure 1: Performance of bilinguals and monolinguals on symbolic math tasks**

A paired-samples t-test was conducted to determine the effect of bilingualism on solving symbolic math tasks. There was no significant difference between monolinguals ( $M=0.97$ ;  $SD=0.18$ ) and bilinguals in easier tasks ( $M=0.79$ ;  $SD=0.41$ );  $t(60)=2$ ,  $p=0.05$ . No evidence exists that bilingualism

has an effect on solving easy symbolic math tasks that require abstract reasoning. Similarly, there was no significant difference between monolinguals ( $M=0.75$ ;  $SD=0.44$ ) and bilinguals in medium tasks ( $M=0.83$ ;  $SD=0.38$ );  $t(60)=2$ ,  $p=0.05$ . Thus, no evidence exists that bilingualism has an effect on solving medium symbolic math tasks. However, there was a significant difference between the group of monolinguals ( $M=0.1$ ;  $SD=0.034$ ) and the group of bilinguals in the solution of difficult math tasks ( $M=0.22$ ;  $SD=0.041$ );  $t(60)=2$ ,  $p=0.05$ . Hence, we concluded that bilingualism influences the ability to solve difficult symbolic math tasks requiring advanced abstract thinking.

Bilinguals in our study performed better, particularly with the difficult problems. The advantages observed here illustrate that bilinguals may be faster to adapt to the demands of novel math tasks. Higher performance suggests that bilinguals may have some advantage in implementing the understanding of new symbolic rules in a new context. These results show that bilinguals can have superior skills in flexible selection and application of new procedures compared to monolinguals.

## Discussion

Most prior research focuses on the problems encountered while learning mathematics and teaching mathematics to bilinguals and students whose home language is not the language of instruction. However, as the current study shows, bilingualism can facilitate the development of abstract thinking, which is consistent with Planas (2014). Since our sample was small, we cannot make global conclusions about the advantage of bilingualism in abstract reasoning. However, our research confirms to some extent the results obtained by Mielicki, Kacinik and Wiley (2017) for USA college students that bilinguals solve better difficult mathematical problems that require advanced abstract thinking. Our study found that bilingual students coped better with difficult abstract mathematical problems. This is how the synergetic effect of bilingualism and experience in abstract thinking manifested itself; it became obvious in those tasks that contained more ambiguity.

It is believed that executive functioning plays a crucial role in solving problems and previous studies have shown the benefits of executive functioning among bilinguals (Adesope, & Ungerleider, 2010; Bialystok, Craik, & Luk, 2012). The advantage of bilinguals in the development of executive functions could also explain the results obtained in this experiment, because memory, inhibitory control, fluid intelligence, mental flexibility and selective attention are involved in the abstract reasoning process while solving abstract math tasks.

One of the drawbacks of our investigation is the assumption that the monolingual and bilingual groups used in the study were truly comparable in every aspect, except for their linguistic skills. Paap and Greenberg (2013) expressed concern that some previously identified differences between monolinguals and bilinguals might actually be the result of differences in socioeconomic status between samples. Since socioeconomic status is known to be associated with different cognitive skills, it is important to ensure that monolingual and bilingual samples come from the same socio-economic background and share other important family characteristics (e.g., parents' education). This fact should be noted, thus an alternative explanation based on the status differences among the bilingual and monolingual participants cannot be ruled out.

Teachers and educators need to be aware of the strengths and weaknesses of bilingual students and teach them accordingly. The differences between bilinguals and monolinguals, if any, are specific to

a particular task and can be quite subtle. Further research can explain our experimental results, which enrich the growing research on the complex picture of the existing effects of the bilingual experience and the strategic intellectual resource of bilingualism when learning mathematics.

# Teaching mathematics in an international class: Designing a path towards productive disposition

Marc Sauerwein

Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany; sauerwein@math.uni-bonn.de

*How can we design a teaching environment for an international class of refugees seizing its natural variety to encourage a path towards productive disposition? The article discusses and evaluates a potential answer by sketching a multiply implemented teaching approach to algebraic expressions and their manipulation via figurate numbers. The intended goal of that approach is twofold: On the one hand challenging pupils' beliefs of mathematics and its teaching, and on the other hand providing a suitable substantial learning environment for the introduction to elementary algebra. As multicultural classrooms, where the language of education differs from the learners' mother tongue, ask for special, language-sensitive teaching approaches, this approach considers the linguistic accessibility and tends to serve as a catalyst for further linguistic and mathematical development.*

*Keywords: Elementary algebra, refugees, genetic principle, figurate numbers, heterogeneity.*

## Introduction

In Germany, IVKs (German abbreviation for International Preparation Class) have been established since 2015 to structure the education of foreign pupils who migrated to Germany. Most pupils are refugees from conflict and war zones all over the world, with medium to non-existent German language skills. In general, pupils can attend these classes for up to two years (depending on the state), and the goals of these classes can be very diverse: different school degrees, transition into the regular educational system or qualifying for the start of an apprenticeship. As in every class there is a natural diversity with respect to the pupils' mathematical giftedness and abilities. However, this natural heterogeneity is intensified by a larger age spectrum (of at least 8 years) and previous experiences in the pupils' various homelands and the conditions of their flight to Germany.

## Modelling strands of heterogeneity

In the tradition of Wittmann's view of mathematics education as a 'design science' (Wittmann, 1995), I identified, in cooperation with various experienced teachers, different strands of heterogeneity in a design research project with multiple implementation cycles (Sauerwein, 2020). A few of these (provisional) strands serve as a basic framework for the reasoning in the article to emphasise the crucial differences between teaching the IVK and regular classes:

- *Communicative strand:* There is no common daily language - neither for informal communication nor for discussions in the classroom. Learning German as a foreign language thus is not only restricted to the classrooms: It encompasses the complete daily routine. The pupils' knowledge of the German language is in-between the levels A1 and B2 (with respect to the CEFRL); some do not even cover A1.
- *Emotional strand:* The linguistic problems are not separated from daily life. This can contribute to an overwhelming frustration of feeling inadequate in nearly every respect of everyday life. Even prior to our project, we observed many pupils approaching mathematics with more courage than other subjects, where they remained passive or even missed lessons.

- *Mathematical strand:* The prior knowledge of mathematics is very individual and reaches from a rudimental number sense in in the number range 1–10 up to twelve years of mathematics education. Moreover, the primary focus in the pupils' previous mathematical education seems to lie on the symbolic languages of arithmetic and algebra.
- *Cultural strand:* Regular school attendance is not part of every culture. In some countries, the pupils are expected to contribute to their families' income. Nevertheless, all pupils had a positive attitude towards school and were grateful for every help. However, for some pupils, a structured week with a time schedule and the learning commitments were new and resulted in an overextension. Rapid changes between gratitude and frustration were observable.
- *Institutional strand:* The school system in Germany probably differs from the pupils' experiences in their respective homelands. According to what some pupils tell me, teaching here is less authoritarian and contains more independent working phases; learning by heart is less dominating. This implies that lessons for these pupils are more demanding as they ask for creativity, self-initiative or mathematical discourse.

### **Problematic consequences**

Although these strands are not explicitly addressed in class, they influence teaching in many subtle ways. For example, different beliefs of mathematics and its teaching seemed to appear in the IVK. These expressed themselves in the following observed misconceptions in practice:

- In mathematics, there is only one correct solution and it's either the teacher's or the calculator's job to decide.
- Mathematics is a finished product and consists mainly of mimicking the teacher's solutions in a formal way with no deeper insights or discussions (in class).

This experience cannot certainly be generalised towards a statement about non-European school systems. These attitudes towards school in general and views on mathematics can prevent the pupils from building sustainable mathematical concepts. On top of that, they can cause challenges with respect to the integration into regular classes.

### **Research question**

The description of different strands of heterogeneity does not imply that these could be addressed separately, as posed in Gorgorió and Planas (2001, p. 28): "It is very difficult to disentangle the social and cultural conflicts of a multiethnic mathematics classroom from the language issues."

As argued before, the above-mentioned intertwined strands influence the teaching. For simplicity we assume that they characterise the heterogeneity in the IVK. The context of an IVK is fundamentally different to bilingual classrooms (e.g., in Malta, Farrugia, 2017; in Catalonia-Spain, Planas & Setati, 2009; in Germany Schüler-Meyer, 2017). In general, one cannot expect to have a common language. The broad research question from the beginning can be rephrased to: Can figurate numbers help to address the special situation within an IVK in a *holistic way* to stimulate a meaningful learning of elementary algebra? In the next section, I address the topic of figurate numbers by building partly on data and findings of my doctoral dissertation (Sauerwein, 2020).

## Figurate numbers

“If human actors invite the object to be a part of the discourse, objects can challenge the students to find a new language [...]. This aspect is of special interest from a didactical point of view. Objects cannot only relieve students on the language level, but also challenge them. They can be ‘supporters’ in the development of mathematical thinking and of a precise mathematical language.” (Fetzer & Tiedemann, 2015, p. 1392)

Inspired by typical generalising approaches to algebra (e.g. Mason, 1996) we define a *figurate number* as a sequence of dot patterns including the corresponding integer sequence:

Figure 1: "3, 6, 9, ..."

As the definition is based on sequences and thus incorporating the (hidden) rule of construction, Figurate numbers demand naturally for a pursuit to find this rule. In keeping with Bruner's (1966) three modes of representation of knowledge, enactive – iconic – symbolic, figurate numbers possess iconic and symbolic components. The iconic nature allows the pupils of the IVK to find linguistically more accessible common ground for mathematical discussions and development.

Such workshop languages [or intermediate languages] which are characterised by a high vividness, situatedness and grammatical looseness, which are often supported by gestures and which may hardly be comprehensible to non-participants, will emerge inevitably from themselves and their communicative importance must be highly appreciated. (Winter, 1978, p. 13, my translation)

It should be noted that, although the language is more accessible, it does not result in a cutback with respect to the richness of its mathematical content. Similarly, Moschkovich (1999) implicitly criticises some teaching practices which limit the pupils' opportunities by the early introduction of compulsory mathematical vocabulary:

“[...] [L]anguage learners can and do participate in discussions where they grapple with important mathematical content. [...] But it is only possible to uncover the mathematical content in what students say if students have the opportunity to participate in a discussion and if this discussion is a mathematical one.” (Moschkovich, 1999, pp. 18-19)

## Practical perspective

Each of the four implementations of the learning environment *Figurate Numbers* started with the dot pattern in Figure 1 which was easily continued by all pupils in an iconic way. In almost all cases – with one interesting exception mentioned below – the resulting dot pattern was a  $3 \cdot 4$ -rectangle. Since not all pupils knew the word for rectangle, they used gestures to distinguish between columns and rows while saying a number, meaning the number of dots in that particular part of the dot pattern. In this way, they were eventually able to describe the pattern and its underlying rule of construction:

- The next dot pattern consists of three horizontal rows with four dots each.
- The next dot pattern consists of four of these columns.
- One always adds the first dot pattern.

- The right dot pattern consists of the preceding two.

The first three descriptions imply that the next dot pattern consists of 12 dots. From there on, many pupils continued the number sequences in a symbolic mode, thus identifying it with the multiples of 3. Although this change of mode of representation seems to be economic, one loses some structure: The expressions  $3 \cdot 4$ ,  $3 + 3 + 3 + 3$  and  $9 + 3$  all yield 12, but each of them also encodes a certain perspective onto the iconic representation, namely how it is structured and consequently counted.

What is the meaning of the fourth description? The pupil's idea incorporates the triple Fibonacci-Numbers. Cutting the dot pattern horizontally it is easily be seen that the pupil's construction is the law of construction of the Fibonacci-Numbers 1, 1, 2, 3, 5, .... Pupils were confronted with the fact, that different views on the given data permitted different and equally legitimate solutions; while the multiples of three later offered an obvious description as a closed term the pupils discovered the essential truth that mathematical observation, if taken seriously, might lead to open ends which cannot be immediately tied up on the basis of available knowledge. Therefore, it is fair to say that this insight was achievable due to the different perspective on the innocent looking figurate number.

Consider now the *filling glass*:

Figure 2: "6, 10, 14, ..."

The filling glass with its richer iconic structure allows more different approaches to counting. Pupils introduced the notion of “negative points” (the missing points in the lowest row) to arrive at “recipes” like  $4 \cdot 4 - 2$ , they observed symmetry (arriving at  $2 \cdot (2 \cdot 3 + 1)$ ). To communicate these ideas the pupils used gestures and inscriptions into the dot patterns, thus enriching them – as diagrams - with a basis for socially accepted reasoning (in the sense of Dörfler, 2006). All these views are potential starting points for generalisations. When changing the iconic pattern is allowed too (for instance changing the position of the two points to a position below the first two columns), more terms can be found, and the observation of equivalence can be generalised to consider terms as objects for further studies and in this context understanding equality among terms on a level beyond syntactical limits.

When in a later state, pupils manipulate terms according to algebraic rules they can, if necessary, find in adapted iconic representations and the study of their geometric transformability into each other a reliable basis for their mathematical discourse.

### Meta perspective

In the beginning of each implementation of our project we were met with the pupils' objection that these dot patterns were nothing but a puzzle for children and no mathematics at all. This pupils' prejudice, which can well be understood from the mathematical and institutional strands explained above, in the course of our project changed into a qualified appreciation of the subject.

Presenting patterns of small dots (i.e. the iconic representation of the first few elements of a figurate number) proved to offer several possibilities and – referring to our intentions – advantages, which are closely related to their “simplicity”:

- Each pupil can count the dots; hence the figurate numbers create a productive entry for different levels. Since in our project every pupil had a certain fluency in counting activities and basic arithmetic (even if limited to a certain range of numbers) the low-threshold accessibility of our project could be taken for granted.
- No tools such as calculators or other digital tools are needed. Only a piece of paper, a pencil and a rubber are needed to gain access to the dot patterns. Taking up on Mason's (1996) distinction of *looking at* vs. *looking through*, the plainness combined with a thorough investigation offers the chance to look through the particular pattern and grasp the general rule. Thus, the picture becomes literally a “diagram” (Dörfler, 2006) and a tool for new insights.
- All but one pattern which we used in our design project corresponded to linear counting expressions. From a mathematical viewpoint these expressions are rather elementary. As this form of representation is new to the pupils, they have to accept and discover the iconic representations as worthwhile objects of further studies and later the possibility to switch between different representations, for example between the dot pattern and the number (maybe written as sum or product) as a tool to prove the validity of an algebraic argument.

This outlined simplicity yields a situation where pupils can express their own ideas even though their skills of the German language would not allow them to do so. The stimulated discussions between the pupils were making use of a certain *intermediate language* (Winter, 1978): The iconic representation becomes the basis for discussion enriched with gestures and rudimental symbolic notations. Winter emphasises the necessity of this intermediate language as a foundation for the symbolic language. Thus, he argues, one should not rush through this stage.

### Epistemological perspective

An historical and epistemological analysis of Kvasz (2008) suggests that figurate numbers were a crucial step for the development of the symbolic language of algebra. Kvasz points out that there was no direct development from arithmetic to algebra as Frege proposed (1891). Instead, there were two instances of a certain *pattern of change* which he calls *re-coding*:

**Figure 3: The *Re-coding* Arithmetic – Geometry – Algebra**

Considering arithmetic and algebra as symbolic languages and geometry as an iconic language, *re-coding* can simplistically be seen as change of the mode of representation. The first *re-coding* is strongly related to the Pythagoreans who invented figurate numbers by using  $\psi\eta\phi\omicron\iota$  (calculi). A first detailed account on figurate numbers can be found in Nikomachos' *Introduction to Arithmetic* (D'Ooge, 1926) where he introduces polygonal and polyhedral numbers apart from the two fundamental sequences of quadratic and oblong numbers (Figure 4). By the inscribed gnomons it is

easily possible to continue each sequence. The second *re-coding* is the symbolisation of the notion of a variable which was only implicitly used as a line segment of indefinite length, thus freeing the variable from three-dimensional space. The analysis of Kvasz and his view on the language of mathematics with its different stratifications where each layer has its own *potentials* (or *cognitive aspects*), yield the necessity to widen the definition of algebra as calculating with letters – it is more than just arithmetic with letters. The introduction of the symbol notation is only the first step to a new symbolic language (Kvasz, 2012). It also involves new ways of operating with the newly introduced symbols. Therefore, one can conclude that typical mathematical activities such as generalising, conjecturing, proving, etc. are part of the use of the language of algebra.

**Figure 4: The quadratic and the oblong numbers**

### **Communicative and linguistic connotations of figurate numbers**

The notion of language occurs in different contexts within this report. These contexts are strongly related to different aspects of figurate numbers. On the one hand, there is language as a medium of communication. According to the communicative strand this function influences all teaching in the IVK. In this sense of language, figurate numbers serve as a tool for discussion of pupils without a common language. On the other hand, they act as a vehicle in a process of conceptualisation, that is, the conceptualisation of the iconic manipulations which lead to language of elementary integer algebra in the sense of Kvasz (2008).

In contrast to the perspective of Kvasz which describes the development of mathematics, the individual process of learning algebra is not linear and straightforward. From a didactical point of view, the pattern of re-coding should be used in both ways. Consequently, figurate numbers become a mediating tool between the languages. In particular, the interplay between the iconic and symbolic components of a figurate number turned out to be fruitful. Figurate numbers opened a context where pupils could conjecture, generalise, prove, discuss, etc.

### **Résumé**

The aforementioned examples from practice showed that figurate numbers can address the special situation in an IVK by seizing the mathematical and communicative strands: The appearance of different counting strategies led to different counting expressions for the quantity of dots and ultimately to the quest to prove equivalence of different solutions on a legitimate and more concise basis than merely counting dots in examples. The iconic form of the figurate numbers served as a sustainable and workable representation compensating the lack of a common language in the class.

Furthermore, the other strands of heterogeneity were confronted: The pupils in the IVK were not familiar with the possibility that there could exist various correct solutions and that mathematics could consist of more than numbers and symbols. Thus, the opportunity arose to tackle the mentioned misconceptions. Moreover, the correctness of a solution was not judged by the teacher; it followed from a consistent argument based on different perspectives of the structure of figurate numbers. It could be observed that the sketched approach to figurate numbers was not only addressing the strands

of heterogeneity and some of their consequences but also contributing to the ambitious goal of the pupils' empowerment.

The strands of heterogeneity cannot be treated separately as they are strongly intertwined. Nevertheless, the initially observed positive attitude within the IVK towards mathematics seemed to be an appropriate starting point: This inclination of the pupils encouraged me to develop it into a "productive disposition" (NRC, 2001, p. 116).

The figurate numbers here act as a generic example for the context of elementary algebra. It could be worthwhile looking for other subject matters with similar potential with respect to mathematical and linguistic development in this social and cultural context of an international class for refugees.

## Acknowledgments

I want to thank the pupils of the IVK for their cooperativeness and the Otto-Kühne Schule in Bonn for all the support and opportunities to conduct the research. Moreover, I would like to express my gratitude for the long discussions with Carl-Peter Fitting leading to the report in its present form.

# Which factors coincide with mathematical learning gains in bilingual classrooms? German language proficiency and mixed language use

Alexander Schüler-Meyer<sup>1</sup>, Susanne Prediger<sup>2</sup>, and Henrike Weinert<sup>2</sup>

<sup>1</sup>TU Eindhoven, The Netherlands, a.k.schuelermeyer@tue.nl

<sup>2</sup>TU Dortmund University, Germany

*Although bilingual mathematical learning opportunities have often been requested for multilingual students, little quantitative evidence has been provided that activating two languages has measurable effects on learning gains. This study uses data from a bilingual teaching intervention to investigate which factors coincide most with the mathematical learning gains in conceptual understanding of fractions. Students' individual and family characteristics have been assessed and participation and language use have been coded in ~95h videotaped teaching-learning processes. A regression analysis shows that students' learning gains can best be explained by students' German language proficiency and their use of Turkish and mixed mode, while talking time did not coincide with learning gains. Thus, the connection of languages seems to be even more important for mathematical learning gains than the isolated use of home languages or active participation.*

*Keywords: Multilingual math learning, teaching intervention, supply-use-model, learning gains.*

## Research gap on factors for effective multilingual mathematics learning

Many qualitative case studies illustrate benefits of activating multiple languages in mathematics classrooms (Planas, 2014). Multilingual resources have been shown to support mathematics learning and engaging students in discursive practices of problem solving, when drawing on multilingual everyday experiences (Domínguez, 2011). In fact, multilingual resources can support problem solving processes in general (Wagner, Redder, Kuzu, & Prediger, 2018), especially when students are highly proficient in their languages (Clarkson, 2006). Furthermore, the activation or acknowledgement of students' multiple languages can have a positive effect on students' agency (Norén, 2015). Summing up, multiple positive effects have been qualitatively identified. However, little *quantitative* evidence could so far be provided that bilingual interventions have *measurable* effects on the mathematical learning gains (Reljić, Ferring, & Martin, 2015).

In order to close this research gap on quantitative evidence, the project MuM-Multi conducted a randomized control trial with Turkish-German seventh graders comparing a bilingual and a monolingual German intervention aiming at conceptual understanding of fractions in small group teaching (Schüler-Meyer, Prediger, Kuzu, Wessel, & Redder, 2019a). The analysis showed that on average, mathematical learning gains in the bilingual intervention were comparable to the corresponding monolingual intervention. The differential analysis of learning gains shows that they were significantly higher for the students with high Turkish language proficiency (ANOVA:  $F_{(\text{group} \times \text{time})} = 4.49$ ,  $p < .01$ ,  $h^2 = .16$ ). Additionally, a strong variance in learning gains was found for the different small groups (for which Cohens  $d$  varied between -0.12 and 2.22). A first hypothesis was that these differences might be traced back to different intensity in Turkish modes.

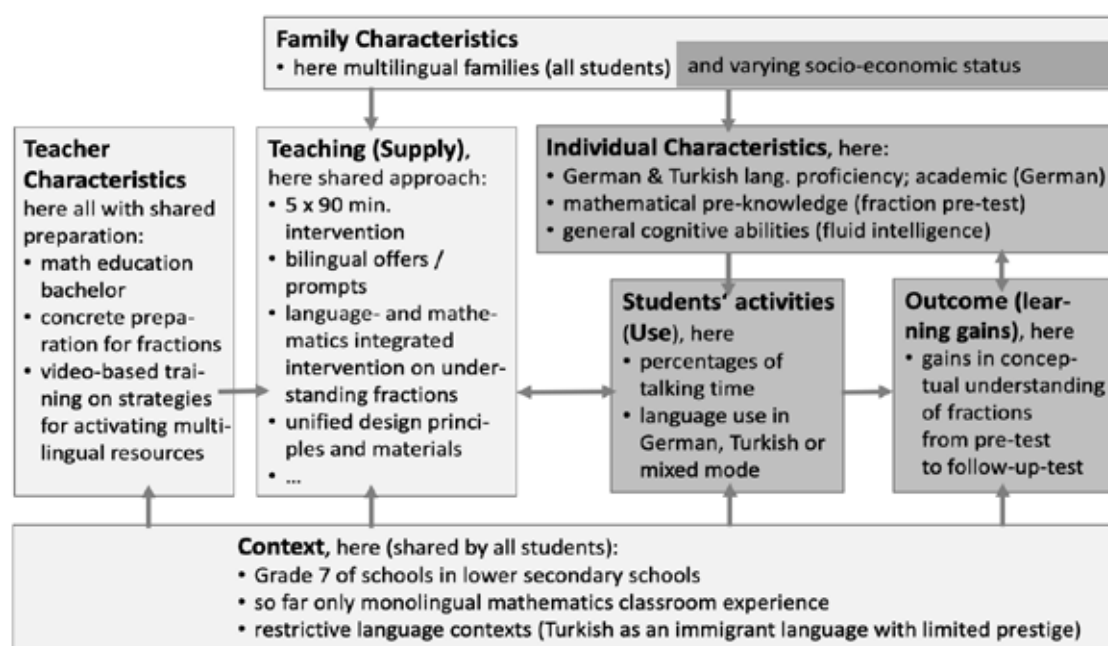

Hence, this study systematically investigates the factors contributing to the effective use of multiple languages in mathematics classrooms. For this, a video analysis was conducted to capture students' language use (Schüler-Meyer, Prediger, Wagner, & Weinert, 2019b) with this research question:

*Which factors in individual and family characteristics and students' language use significantly coincide with students' learning gains in the bilingual teaching intervention?*

This research is framed by the supply-use-model (Brühwiler & Blatchford, 2011; Helmke, 2009), which is outlined in the next section, before the methods of the study and its results are presented.

## Research framework: Supply-use-model for quantitatively capturing potentially relevant factors for bilingual interventions

The supply-use model (Brühwiler & Blatchford, 2011; Helmke, 2009) has often proven to be powerful in quantitative classroom research for modelling the factors that influence whether a *supplied* learning opportunity is really *used* to its full potential by students in a classroom and how this impacts the learning outcome. The assumption is that the relations between supply, use and outcomes (learning gains) can be influenced by context factors or students' individual or family characteristics. Figure 1 shows the general model and its adaptation for the current research (justified in detail in Schüler-Meyer et al., 2019b).

**Figure 1: Supply-Use-Model adapted from Helmke (2009) by Schüler-Meyer et al. (2019b)**  
(factors held constant are colored in light grey, varying factors in dark grey)

Following the research question, we investigate the learning processes of multilingual seventh graders with equal conditions in the language context (cf. Schüler-Meyer et al., 2019a): All students stem from multilingual Turkish-German families (all factors held constant are colored in light grey in Figure 1), their shared language context is shaped by only monolingual math classroom experiences and the limited prestige of their home language Turkish. All small groups are taught by teachers which share many characteristics and preparations. They follow the same bilingual intervention with

equal design principles and teaching materials, thus the *supplied* learning opportunities are held constant in the bilingual intervention on fractions.

The research question focuses on the individual *use* of supplied bilingual learning opportunities (in terms of percentage of individual talking time and language use) and students' *characteristics*. 'Percentage of individual talking time' was chosen as a use factor because active participation has often been qualitatively described as influencing learning gains (Gresalfi, Martin, Hand, & Greeno, 2009). The second *use factor concerns individual language use*: As all prior math experience was monolingual German, it was crucial to control whether students really use both of their languages. Like for most multilinguals, the bilingual modes are expected to be characterizable by mixed modes (e.g. various forms of Code-switching between German and Turkish), also for the second- and third-generation Turkish immigrant students (Auer, 2010).

## **Methodology of the study in the supply-use-model**

### **Design of the bilingual teaching intervention**

The investigated bilingual Turkish-German teaching intervention was designed to foster the conceptual understanding of fractions, which encompasses the part-of-whole concept, equivalence, and order of fractions. The intervention consists of five 90-minute weekly sessions and builds on three principles for fostering multilingual learning (cf. Schüler-Meyer et al., 2019a): (1) Providing rich contexts and problem tasks for language production (Domínguez, 2011); (2) macro-scaffolding, which included encouraging the use of Turkish with bilingual teaching material, bilingual teaching practices (e.g. revoicing), explicitly addressing and developing the Turkish and German academic language, and (3) systematically relating registers (Prediger, Clarkson, & Bose, 2016).

### **Design of the overarching project MuM-Multi and video corpus for the current study**

The randomized control trial (Schüler-Meyer et al., 2019a) was conducted in a pre-post-follow-up design with conceptual understanding of fractions as dependent variable. The family and individual characteristics mentioned in Fig. 1 served as control variables and the contrast between mono- and bilingual intervention served as the independent variable. The groups in the bilingual intervention were taught by trained Turkish-German speaking preservice teachers in small groups of 2-5 students, for 5 sessions of 90 minutes. This study focuses only on the bilingual intervention, for this 13 x 90 minutes video material of the third session was coded from 13 small groups. The third session in the middle of the intervention was chosen because teachers had developed their routines, and the students had a chance to overcome first barriers of using Turkish in the classroom.

### **Measures for data collection for the individual and family characteristics**

At three measurement time points, several measures were administered:

- *Measures for students' conceptual understanding of fractions.* The test has 28 items to test for the understanding of the part-of-whole concept, equivalence, and order of fractions. The test has a satisfactory internal consistency with Cronbach's  $\alpha=.83$  (28 Items,  $N=1120$ ).
- *Measures for students' socioeconomic status and general cognitive abilities.* Students' socioeconomic status was measured with the economic and reliable book scale ( $r=0.80$ ). The students'

fluid intelligence was measured using an adapted matrix test BEFKI 7 (with Cronbach's  $\alpha=.763$  in the initial full sample of  $N=1124$ ).

- *Measures for German and Turkish language proficiency.* Students' language proficiencies were measured by C-tests, which provide an economic and valid measure based on cloze texts. The C-tests are highly reliable: the Turkish C-Test with  $\alpha=.874$  ( $N=254$ ) and the German C-Test with  $\alpha=.774$  ( $N=1122$ ). Students' German academic language proficiency is measured with a test which assesses the use of nominalizations and other academic language features (BiSpra).

### Initial sample and sample of the bilingual teaching intervention

The initial full sample encompasses  $N=1124$  seventh-grade students from twelve secondary schools (48% female and 52% male). From the 303 Turkish speaking students, a subsample of 254 students self-selected themselves by accepting to work on the Turkish C-test (Table 1). For the intervention, students with a low conceptual understanding of fractions were selected (Cut-off of 28 points in the fraction test). This group consisted of  $N=128$  students who were then stratified along the control variables and randomly assigned to the intervention groups. The sample of this study consisted of  $n=35$  students who participated in the third sessions of the bilingual teaching intervention on fractions. Due to missing follow-up data, the statistical analysis has a sample of  $n=33$  students.

	Initial sample ( $N=1124$ )	Bilingual subsample ( $N=254$ )	Sample of this study ( $n=35$ )
<b>Family characteristics</b>			
Percentage of German-Turkish speaking students	27%	100%	100%
Socio-economic status (low, medium, high SES)	35%, 33%, 31%	38%, 30%, 31%	40%, 20%, 40%
<b>Individual student characteristics</b>			
Mathematics achievement by fraction pre-test, $m(SD)$	10.31 (4.73)	9.81 (4.69)	8.03 (2.70)
General cognitive ability by BEFKI, $m(SD)$	7.94 (3.41)	7.25 (3.23)	7.49 (2.72)
Turkish language proficiency by C-Test, $m(SD)$		23.95 (13.17)	25.97 (13.07)
German language proficiency by C-Test, $m(SD)$	35.27 (9.17)	33.18 (8.34)	32.77 (5.52)
German academic language prof. by BiSpra-Test, $m(SD)$	19.06 (5.34)	17.03 (4.92)	17.20 (4.35)
Age by self-report, $m(SD)$	12.76 (0.70)	12.79 (0.78)	12.77 (0.65)

**Table 1: Descriptive data for the full sample, the bilingual subsample, and the sample of this study**

### Methods of data analysis I: Coding the video corpus of the third intervention sessions

All utterances of the students (S1-S4) and teachers (T) were categorized turn-wise with respect to (a) speaker and starting / ending time of the utterance, and (b) language use (Turkish, German, mixed mode). Utterances with one switch from one language to the other were splitted and each part categorized. Utterances with borrowings or multiple code-switchings were coded as mixed mode. This categorization captures lexical aspects of language, while grammatical mixes are left out. The duration of the utterances is used for operationalizing the two use factors.

- *Percentages of talking time:* The operationalization of participation has to account for the fact that students in differently sized groups have different allotted talking times. Two students and a teacher theoretically have 30 min. of talking time each, while four students would only have 18

min. Hence, the allotted talking time is the theoretical talking time per group member with  $x$  group members, hence  $90/x$ . The individual percentages of talking time is the share of actual talking time from the allotted talking time (which can be bigger than 100%). Students on average participated 90,45% of the allotted talking time. The averages in the groups are between 72% and 110%, and the individual participation varies between 20% and 210%.

- *Modes of language use:* The individual language use is operationalized as the share of Turkish, German and mixed modes from the total individual talking time. Table 2 shows the descriptive data for the modes of language use.

## Methods of data analysis II: Hypotheses and model for the statistical data analysis

For statistically investigating the research question, the following hypotheses were validated by correlations: The learning gains of the bilingual intervention is connected to **H1** the percentage of talking time; **H2** the Turkish language use; **H3** the language proficiency in Turkish and German. For comparing the influences of factors, a regression analysis was conducted with the software R (<https://cran.r-project.org/>) for validating Hypothesis **H4**: Among the different factors, some exist which coincide significantly with the learning gains. If a Shapiro-Wilk test confirms the normal distribution, Pearson's Product-moment correlations  $r$  were determined, if not, Kendall's Tau  $\tau$  was used. To rule out an effect of the groups on the investigated variables, the intra class correlation ICC was determined and tested for significance with boot-strapping.

## Results

### Descriptive findings for the modes of language use

Table 2 shows that both, teachers and students, participated in bilingual modes, i.e. in a mixed mode or in Turkish. On average, 52% of the overall talk time was Turkish or mixed (72% teachers, 30% students). Hence, there is a high degree of productive and receptive use of Turkish. Furthermore, a large percentage of the talk time is in mixed mode, so that both teachers and students seem to use every-day bilingual practices of code-switching and -mixing. However, individually, there are substantial differences in the language use. The group averages between teachers and students also vary strongly. This suggests that individual preferences of language use might in part be a result of group-specific practices of activating multiple languages. Nevertheless, in a teaching intervention in which teachers consequently invest in the use of Turkish and mixed language, these numbers show that students can nevertheless be engaged in bilingual learning processes, compensating the low prestige of Turkish and the previous monolingual education.

	German mode	Mixed mode	Turkish mode
Teachers' average use of languages	27.5%	34.6%	37.4%
Students' average language use (all groups)	68.9%	13.6%	16.2%
Teachers' span of language use (min. – max. of the groups)	9.2% – 53.5%	15.7% – 56.4%	12.7% – 72.0%
Students' span of group average (min. –max. of the groups)	51.3% – 85.2%	4.9% – 26.5%	2.5% – 36.1%
Students' span of language use (min. – max. of all students)	16.1% – 96.8%	0% – 32.3%	1.5% – 56.1%

**Table 2: Distribution of modes of language use for teachers and students (n=37 students)**

### Findings of influences of different factors

For investigating Hypotheses **H1–H3**, correlations were determined between the learning gains (difference between pre-test and follow-up-test) and the potential factors: The correlation with the German language proficiency is  $r = 0.38$ , with the Turkish and mixed modes in language use it is  $r = 0.32$ , these are two relatively high correlations. For the language use of only Turkish modes, the correlation is low with  $r = 0.14$ . No correlation exists with the percentage of individual talking time where  $r = -0.03$ . Thus, the hypothesis on relevance of active participation must be refuted.

To investigate the joint effects of the different factors on the learning gains (H4), a regression analysis with a stepwise model selection was performed (Table 3). As the learning gains of the small groups provide a non-significant ICC-value of 0.29 ( $p > .05$ ), a multiple linear regression model is adequate.

	Regression coefficient b	Standard error (b)	Standardized regression coefficient
<b>Model 1: All variables</b> ( $R^2 = 0.35$ , $R^2(\text{korr.}) = 0.14$ , $F(7,22) = 1.68$ , $p > .05$ )			
Intercept	-9.45	6.2	
German language proficiency (C-Test)	0.32	0.17	0.40
Fluid intelligence (Befki)	-0.0007	0.33	-0.0004
German academic language proficiency (BiSpra)	-0.05	0.26	-0.05
Turkish language proficiency (C-Test)	0.034	0.09	0.10
Socio-economic Status (Book index)	0.79	0.82	0.20
Use of Turkish and mixed mode	5.25	4.88	0.23
Percentages of talking time	-0.91	1.91	-0.092
<b>Model 2: After systematic model reduction</b> ( $R^2 = 0.35$ , $R^2(\text{korr.}) = 0.30$ , $F(2,30) = 7.973$ , $p < .01$ )			
Intercept	-9.90 *	4.17	
German language proficiency (C-Test)	0.34 *	0.13	0.41
Use of Turkish and mixed mode	6.90	3.64	0.30
<b>Model 3: Only German language proficiency as variable</b> ( $R^2 = 0.27$ , $R^2(\text{korr.}) = 0.25$ , $F(1,31) = 11.39$ , $p < .01$ )			
Intercept	-10.63 *	4.32	
Proficiency in German	0.44 **	0.13	0.52
<b>Model 4: Only Turkish and mixed modes as variable</b> ( $R^2 = 0.20$ , $R^2(\text{korr.}) = 0.18$ , $F(1,31) = 7.873$ , $p < .01$ )			
Intercept	0.28	1.45	
Use of Turkish and mixed mode	10.33**	3.68	0.45

**Table 3: Results of the regression analysis with stepwise model selection**

Model 1 with all variables, while being complete, is not significant. A stepwise model selection results in a significant Model 2 ( $F(2,30)=7.973$ ,  $p < .01$ ), which includes German language proficiency as significant factor for learning gains ( $p < .05$ ). In comparison, Model 3 and 4 are models with single variables, namely German language proficiency and the use of Turkish and mixed mode, respectively. Overall, Model 2 has the best model accuracy with  $R^2(\text{korr.})=0.30$ . This model shows that a higher German language proficiency leads to higher learning gains: One additional point in the C-test leads to higher learning gains of 0.34. Also, the use of Turkish and mixed language is a relevant factor: 10% more use of Turkish and mixed language leads to 0.69 more points in the learning gains.

In sum, the learning gains in the bilingual teaching intervention coincide with the German language proficiency, but not the Turkish language proficiency or the German academic register. This student

characteristic is combined with the use factor ‘use of Turkish and mixed mode’, which also shows a strong connection to learning gains.

## Summary and discussion

This study contributes to the research discourse on multilingual mathematics learning as follows:

- Within usual language policies of monolingualism, the percentage of the mixed-language mode used by teachers and students is remarkable (Norén, 2015). By implementing certain principles for activating multiple languages, multilingual students can be fostered to activate their multiple languages in mathematical teaching learning situations, despite a language context which devalues the immigrant language Turkish.
- The finding that the share of Turkish and mixed language use in students’ utterances best explains the learning gains in the bilingual teaching intervention (together with German language proficiency) is a quantitative evidence for many qualitative results which show how multilinguality can be a resource in learning processes (Planas, 2014; Norén, 2015).
- The students’ percentage of individual talking time is not correlated to the learning gains. This confirms skepticism on too simple conceptualizations of active participation as talking time.
- In light of studies illustrating how conceptual tasks involving problem solving are especially accessible to multilingual students by means of certain discursive practices like discussing (e.g. Dominguez, 2011), the finding that students’ German language proficiency significantly coincides with the growth of conceptual understandings may hint at a more complex relation between conceptual tasks and their utilization in discursive practices, and the languages used.

Interestingly, not the share of Turkish from an individual student’s talk time, but the share of Turkish and mixed mode *together* have the second strongest influence on the long term achievement (Table 3). This is in line with Auer (2011) who identifies the mixed mode as the norm for Turkish-German multilinguals, and not the “pure” use of Turkish. This suggests that in bilingual classrooms the multilingual register and mixed mode are central pillars of the classroom discourse. Furthermore, it may suggest that a mixed mode allows deeper conceptual understanding (Wagner et al., 2018). Hence, in spite of its methodological limitations, this study confirms research which hints at the relevance of activating multiple languages in learning processes.

## Acknowledgment

“MuM-Multi: Fostering Language in multilingual mathematics classrooms effects and conditions of a content- and language integrated intervention” was funded by the German ministry BMBF (01JM1403A, grant holders S. Prediger, J. Rehbein & A. Redder). We thank T. Kuzu, A. Redder, J. Rehbein, J. Wagner, and M. Çelikkol.

# **Publishing as an English non dominant language author. First results from a survey of support offered by mathematics education journals**

Rudolf Sträßer (Straesser)

Justus-Liebig-University, Giessen, Germany & Australian Catholic University, Brisbane, Australia

rudolf.straesser@math.uni-giessen.de

*With English as the language of the vast majority of highly regarded international journals in Didactics of Mathematics (research in mathematics education), authors who do not have English as their dominant language face the challenge of producing a text in a target language different from their working language (source language). The paper presents first results of a survey on how a number of highly recognised international journals in Didactics of Mathematics handle this issue and identifies some of the related challenges. Some challenges are linked to specific customs and norms related to the generation and credentialing of new knowledge within communities of research practice. Others are connected to semantic and pragmatic characteristics of transforming thoughts and texts from a source to a target language. The paper also provides insight into types of support offered by major journals to English non-dominant language authors.*

*Keywords: Translation, heteroglossia, centripetal versus centrifugal forces, journal survey.*

## **Coming to the issue**

This paper started in the experience of the author when publishing in journals of Didactics of Mathematics where the English language was obligatory. As I am not a native nor dominant<sup>1</sup> English speaking author, I had to express my ideas in English, which I had developed in a German speaking scientific community. My way out of this dilemma was asking a friend (Vince Geiger) to help me with transforming my texts from German English to Australian English. After some experiences with this simple arrangement, we came to reflect on this practice – what ended up in a presentation at a conference and later in a journal publication (see Geiger & Straesser, 2015). This publication was very well received and encouraged us to continue work on publishing about the issue of English non dominant language (EndL) authors in scientific journals of Didactics of Mathematics (see Geiger & Straesser 2017; Geiger, Margolinas, & Sträßer, 2018). In this paper I aim to progress this line of research inquiry by examining the ways in which major journals in mathematics education provide support for non-dominant English language authors.

## **Helpful concepts and ideas**

In addressing the issue of the challenges faced by EndL authors when attempting to publish in major international journals in mathematics education, two major issues stand out: the transformation from a source language into a target language, and heteroglossic considerations. Publishing as an English

---

<sup>1</sup> The word “dominant” is used deliberately, because it best covers the situation to be analysed. The Merriam-Webster Dictionary offers two major explanations for “dominant”: “more important, powerful, or successful than most or all others” or “most common”. As can be seen for some colleagues, the dominant language is not always the language with which a person has grown up. “Dominant” also captures the power relation inherent in the dominance of a language.

non dominant language author in scientific journals inevitably invokes the challenge of transforming one's own dominant language, the *source language*, into English as the dominant language of international scientific discourse and of majors journals, which, at least in Didactics of Mathematics, is into the *target language* English – see section 3 for typical pitfalls as identified in the German/French/English context.

There are also challenges related to issues within a single language – normally discussed inside linguistics under the concept of *heteroglossia*. Heteroglossia was coined as a concept by translators of Bakhtin and provides a perspective relevant to learning a language different from a dominant language. The concept refers to the diverse, multiple layers of meaning and understanding embedded within speech and speech types (Barwell, 2014). In this respect, Busch (2014) distinguishes “between ... the multiplicity of (social-ideological) speech types or discourses, ... the diversity of (individual) voices, and [the] linguistic variation or the diversity of languages”, in distinguishing between multidiscursivity, multivoicedness and linguistic diversity (see Geiger & Straesser, 2015, p. 37). In particular, Bakhtin’s concepts of “*centripetal*” and “*centrifugal*” forces account for the tension that exists between a variety of languages or language types co-existing in communication within one language (Barwell, 2014). Centripetal forces place pressure on speakers or authors to adopt a single standardised linguistic code - an “official” language that must be adopted to gain full acceptance into a professional community or other social system. Working against this influence are centrifugal forces that push the language used by speakers and authors towards more diverse expression. Centrifugal forces arise because of differences between people, due to multivoicedness, and the multidiscursivity of linguistic diversity associated with geography, culture or membership of specific social groups. Such forces are seen at work within mathematics education through the diversity of its focuses and endeavours.

## Challenges and pitfalls

This section can be read as a summary of a number of types of challenges identified in previous research and draws primarily on work within English, German and French language contexts.

### The question of the name of the discipline

At least for researchers from French or German speaking communities, translating into English first starts with a choice of an adequate name of the researcher's “home discipline”. Is it *Didactique des Mathématiques*, *Mathematikdidaktik* or ... (Research in) Mathematics Education – as expected by anglophone communities? A loophole to this dilemma may be the rarely used *Science of Mathematics Education/Sciences de l'Éducation Mathématique / Wissenschaft vom Mathematik-unterricht*. However, this solution is a marker of a major problem. Different language-based communities of practice of a discipline have chosen to use names for their research activity, now well established and deeply rooted historically, that carry “baggage” when used in other languages. From the European perspective, *Didactique/Didaktik*, for example, has wide acceptance because of the famous *Didactica Magna* by Comenius (1896/1907), often cited as foundational publication from the early days of the discipline. However, for the anglophone researcher *Didactique des Mathématiques/Mathematikdidaktik*, has an undesirable association with “didactic” approaches to teaching and learning (e.g. teacher directed modes of instruction), while *Mathematics Education* for the French

and German speaking researcher is too wide and also covers the day-to-day practice in school, and does not focus on research.

### **Shared and non-shared references and respective theoretical frames**

When developing an annotated translation of the English language article by Geiger & Straesser (2015) into French, we became aware of another major difficulty of EndL authors. Research papers across the disciplines must demonstrate that they take into account existing research on the topic at hand and that they provide a contribution to new knowledge. Translating a paper into another language, however, usually requires additional work because an initial publication in one language tends to have extensive references to research originating from the source language and the tradition within a (national) discipline. Often these lists include few, if any, references from the target language – this holds true even for journals with an international reach and readership, for example, *Recherches en Didactique des Mathématiques* (RDM) or *Educational Studies in Mathematics* (ESM). Unsurprisingly, reviewers tend to look for references in the dominant language of the journal, which for the author/translator may imply a longer search for appropriate papers to be referenced. In the worst-case scenario, this requires a literature search from scratch to have the basic seminal papers of the target language cited. This shift from papers in one language group to another within mathematics education can also require a revised reflection on the results and the re-writing of the results/conclusion section(s) in order to situate findings in a different theoretical landscape.

### **Type of ‘acceptable’ research reports**

Communities of research practice do not only have sets of seminal reference points but often a very clear perspective on how to report on research activities. This is especially true for US-American research in mathematics education with an accepted structure around introduction, methodology, results, discussion and conclusion (Geiger & Straesser, 2015, p. 36). Such a tendency towards prescriptiveness can also be seen in other mathematics education research communities. For example, it is only for some five years that the International Group for the Psychology of Mathematics Education (PME) has accepted not only “Reports of empirical studies”, but also “Theoretical and philosophical essays”. For researchers from the French community, the dominant reporting structure for journals publishing in English, typified by PME, is highly problematic for reports on empirical investigations. For the French researcher, the expected structure requires a description of the theoretical framework that includes an extensive introduction to situate and justify the investigation and the precise methodological choices (the so-called a priori analysis). Further, the PME distinction of results and conclusions hinders an integrated presentation of empirical and often epistemological facets of a research, which would be common in a publication in French. There are also difficulties for German speaking researchers who adhere to the ‘German’ approach to Didactics of Mathematics called *Stoffdidaktik* when trying to follow the traditional PME structure (for this approach see Straesser, 2014 or Hußmann et al. 2016). The focus of research according to *Stoffdidaktik* is on disciplinary mathematics and so scientific progress is often recognised through identifying possible approaches to a specific mathematical topic (i.e. obtained with mathematical, not primarily empirical analysis) and will seldom fit with the definition of empirical investigations prioritised in empirical English language publications.

## Semantic differences in scientific debates in different languages

Translating from a source language to a target language often implies the challenge of “false friends”, i.e. the fact that using a word from the source language in the target language produces incorrect, if not misleading associations. Using the French word (and in French didactics: theoretical concept, see Brousseau 1997, p. 56f and p. 214) *milieu* in English will hide the theoretical role of *milieu* in the French *Théorie de Situation* (TDS), where the concept also includes material aspects of an environment, whereas in English, *milieu* is only designating the social and cultural environment, not its material aspects. As a consequence and from the point of view of semantics, *milieu* has a broader sense in French than in English and so should not be used for a translation from French into English without qualification. If authors, especially those drawing from the French TSD, do not change the term when publishing in English and continue to use *milieu*, they widen the signification of the word in English. Thus, in theoretical terms, they exercise a centrifugal force in the sense of Bakhtin. If authors accept the difficulty of Anglo-phone researchers with the narrow understanding of *milieu* and – in contrast to its use in the TSD – only apply it in the narrow, dominant sense of *social milieu*, they surrender to the centripetal forces of the English language community.

Another challenge may be the absence of two different words from the source language in the target language. Geiger et al. (2018, p. 36f), discusses this case with the example of an adequate translation of the concepts of *savoir* and *connaissance* from French into English. The terminological problems (already existing) in French are exacerbated by the complexity associated with finding an appropriate word in English. The English language does not have the same depth, the granularity for the semantic field, for the term *knowledge*; this limit in vocabulary implies different solutions for the translation of the two French nouns *connaissance* and *savoir*, for example, to use the noun *knowing* for *connaissance* and reserve *knowledge* for *savoir*. Given these difficulties, an author would first require a very clear idea about the differences between these two terms within the Theory of Didactical Situation (TSD) and would then have to find a way to describe and explain this difference in English. By linking *connaissance* and *situation* on one hand and *institution* and *savoir* on the other (see Margolinas, 2014), a linguistic solution may be possible when attempting to communicate with English as dominant language speakers. Adding two adjectives to differentiate the only available noun *knowledge* instead of creating one or two new noun(s) has been used in a course about Brousseau’s work in English commissioned by ICME – with Margolinas and Bessot introducing the terms *situational knowledge* and *institutional knowledge* to deal with this situation.

The situation can be even worse for a translation. What if there is no word in the target language that can convey the meaning of an expression in the source language? In Didactics of Mathematics, the translation of *Bildung* from German into English is simply not possible. While there is a widespread debate in Germany of the relationship of *Bildung* to mathematics education, a number of publications on the topic (e.g., Winter, 1975) and a special topic study group on *Bildung* in the German research association *Gesellschaft für Didaktik der Mathematik* (GDM), this activity has not produced an adequate translation of the term *Bildung* in either English or French. An attempt to translate texts that refer to *Bildung* and its ramifications for mathematics education in German schools, would need an extensive description of the cultural history of the concept *Bildung*, which itself would only be a faint

echo of discussions in the pedagogical and didactical debate in Germany after world-war II (for the respective seminal book in pedagogy see Klafki 1985).

### **How journals in Didactics of Mathematics handle the issue – a survey**

In order to gain insight into the support of EndL authors from major international journals in Didactics of Mathematics / Mathematics Education, a survey of the seven most highly recognised journals in the field was conducted. Journals were identified via the list in a study by Leatham and Williams (2017, especially the list on page 390) into those journals. After trialling the survey with the editor of the journal ranked 8<sup>th</sup>, the editors of the top 7 ranked journals were invited to respond to a survey. The survey was based on questions on the support offered by the journal for EndL authors before, during and/or after the processes of submission, review, proofing and publication. To date, there are five complete responses. Preliminary results of this survey are presented below.

The responses represent a wide spectrum of handling manuscripts from EndL authors. One extreme is the tendency to place all of the responsibility for conforming to a journal's expectations of language usage on the author, clearly communicated in the following response.

We expect language-edited papers for authors, whose mother tongue is not English, but many manuscripts still have strong deficits, when they reach us. We have language editing at the end by NN [name cancelled], but that comprises only a check of correct usage of terminology and correct academic writing.

At the other end of the spectrum, there are comments such as:

Thank you for investigating this important issue. Around 40% of articles published in NN [name of the journal] come from countries where English is not the dominant language, but the proportion of EndL authors is higher than this when one considers all submitted manuscripts. However, some caution is needed in looking for causes of manuscript rejection – language is not the only reason, and perhaps not even the main reason. Many authors struggle to frame and communicate their research so that it is relevant and accessible to an international audience, and this can be a consequence of differences in the significance of research questions across cultural contexts. So language diversity is part of a bigger global challenge in understanding culturally inflected ways of framing and communicating research.

None of the journals that have provided responses to date have a formal, institutionalised provision or special procedure for manuscripts submitted by EndL authors, but at least two of the editors-in-chief, indicated they take special care with such manuscripts. One of them tries:

... where possible, to align the language expertise [of handling editors] with the dominant language of the corresponding author [and tends] to support several rounds of major revisions to help the EndL author produce a publishable article. (Only one or at most two major revisions would be the norm for other manuscripts.) [In addition, the editor-in-chief spends]...many hours on language editing of the penultimate version of each EndL-authored manuscript that I handle. I aim to not only achieve an acceptable standard of academic English but also preserve some of the distinctive linguistic features of the author's first language (lexical choices, syntactic structures, etc.). I want

readers to “hear” the traces of the author’s first language rather than obliterate it and produce a bland and rather boring set of articles in each journal issue.

Another Editor-in-Chief states that

... after a submission is accepted the Editor works with the author(s) to improve the presentation of the article. Depending on the situation this can range from offering advice on rewriting, to offering suggested rephrasings.

In total, in two of the responses, language editing by the editors-in-chief is mentioned. At least one journal Editor indicated it was actively encouraging EndL authors to submit to their journal.

As Editor I actively seek contributions from non-English speaking researchers. ... This includes requesting members of our Advisory Board, which includes researchers from around the world, to suggest possible authors, and approaching potential authors at conference, etc. When a submission is received the evaluation of it is carried out on the basis of its content, and the editors are experienced in reading work by authors writing in a language other than their mother tongue, and so we are able in most cases to evaluate the content independently of the presentation. Some of our reviewers offer corrections at the grammatical level when commenting on a submission but not all. It is chiefly my responsibility as Editor to address any remaining language issues once an article has been accepted. That is, it is possible for an article to be accepted with ‘heavily accented’ writing. I then work with authors to ensure that their ideas are presented as clearly as possible to ... readers. An approach I have discussed with some potential authors, but which has not yet been implemented, is the submission of articles in a language other than French or English. Our Advisory Board includes researchers who are able to read many languages and so the first stage of our reviewing process (the internal review) could occur in another language.

In addition to this, the same journal even provides complimentary subscriptions to:

...national organizations, or research teams, in countries from which we rarely receive submissions ... on the theory that if more people in that country read [name of the journal], more people will submit articles to it.

Other responses indicate some journals manage the handling of manuscripts by EndL authors via the identification of appropriate reviewers, for example,

Selection of reviewers would take into account multiple factors, including familiarity with the theoretical and methodological approaches and often the local research context, in addition to the author’s language and cultural background.

By looking through the lens of centripetal / centrifugal forces within the major journals, the “standard” position in the answers is “There is no preferred form of English, but there does need to be consistency in using either US or English spelling within an article.” Thus, consistency is generally seen as the vital principle of English language usage. By contrast, the response of one Editor-in-Chief stands out by stating

Our instructions to authors state 'Contributions may be submitted in English or French. (The English may be American, British, or hybrid.)' How exactly this is interpreted has varied from

editor to editor. As I am not personally familiar with many dialects of English, and I find [...] English quirky and inconsistent, I tend to edit submissions to either US or UK spelling. NN style includes a mix of punctuation rules from US, UK and [...] sources, and some that have simply evolved as ‘the way NN does things’. As Editor I take responsibility for making sure the style of each article is close enough to NN style that most readers notice no inconsistencies.

This approach appears to be a special form of centripetal action in that while some diversity is allowed, expression is limited to only three forms of English.

## Conclusion

Two conclusions can be drawn from the previous study of the challenges faced by EndL authors and their opportunities to publish in highly recognised journals. English (in the form of the UK, USA and other dialects or a mixture of them) is the “lingua franca” of international research in mathematics education / Didactics of Mathematics. At the same time, fruitful and innovative research in the field depends on the healthy life of “local” research communities, which need opportunities of publishing ideas and results in the individual dominant language of their “own”. The initial findings of the survey indicate that the support offered to EndL authors attempting to publish in highly recognised journals varies considerably. The spectrum of support ranges from an almost non-interventionist approach through to significant editorial support before publication in journals targeting the broad mathematics education / Didactics of Mathematics community.

## Acknowledgement

I thank Vince Geiger, ACU Brisbane, for his continuous support and advice with writing this report.

# Variations in students' reading process when working on mathematics tasks with high demand of reading ability

Frithjof Theens

Umeå University, Department of Science and Mathematics Education, Sweden  
frithjof.theens@umu.se

*The purpose of this study is to deepen the understanding of the relation between features of the text of mathematics tasks and the tasks' demand of reading ability. Variations in students' reading processes when they work with PISA mathematics tasks with high demand of reading ability are identified and analyzed. These variations can be related to linguistic features of words, phrases, or sentences in the tasks, which in turn can be possible sources for the high demand of reading ability.*

*Keywords: Mathematics tasks, reading comprehension, reading process, PISA.*

## Introduction

Mathematics tasks are a common way to assess students' mathematical knowledge. They are used in examinations, nationwide tests, and also in international assessments like the Programme for International Students Assessment (PISA). They are meant to assess mathematical ability, that is, acquired proficiency in mathematics, but a written task usually also requires that the student can read natural language in the task text, which can make the task also assess reading ability. Some reading ability can be seen as a necessary part of mathematical communication which is an aspect of mastering mathematics (NCTM, 2000). However, to ensure that the task assesses what it is intended to assess and nothing else, *unnecessary* demand of reading ability not connected to mathematical ability should be avoided. This unnecessary demand of reading ability can be caused by linguistic features of the task text which may be avoidable if they are not connected to mathematics (e.g., use of uncommon words not belonging to mathematical vocabulary or complex sentence structure). Therefore, it is important to identify which linguistic features of mathematics tasks are related to an unnecessary demand of reading ability. This demand may become apparent in variations in students' reading process when working with mathematics tasks (e.g., stumbling at a word or rereading a sentence). Analyzing these variations, and identifying the units of the text where they occur, makes it possible to determine features of the task text potentially causing an unnecessary demand of reading ability.

This study thus detects and analyses variations in students' reading processes when working with mathematics PISA tasks identified as having high unnecessary demand of reading ability. Also, features of the tasks' text and their possible impact on the tasks' demand of reading ability are discussed.

## Background

This section presents the theories about reading comprehension and reading of mathematical texts that are used in this study to characterize the variation in the students' reading processes. It will also give a short overview of earlier research concerning sources of (unnecessary) demand of reading ability in mathematics tasks.

## Reading comprehension

A simple description of reading comprehension is given by Hoover and Gough (1990) who describe *decoding* and *linguistic comprehension* as necessary for successful reading. Decoding means the ability to recognize words, that is, being able to connect written words to mental lexical information. Linguistic comprehension is the ability to derive meaning out of lexical information. In the concept of *reading comprehension*, these two are combined into the ability to derive meaning out of written information. In addition, Österholm, Bergqvist and Dyrvold (2016) identify three aspects of reading comprehension that can be related to reading difficulties. These are *phonological*, *syntactic*, and *semantic* aspects. The phonological aspect concerns sound and the flow of reading, since phonological memory supports listening comprehension and thus, indirectly, reading comprehension (Perfetti, Landi, & Oakhill, 2005, p. 238). The syntactic aspect concerns the decoding of grammatical structures at the sentence level. Finally, the semantic aspect refers to the depth and breadth of knowledge of word meaning (Nation, 2005, p. 254).

The different parts and aspects of reading comprehension are used in this study to identify possible sources for issues students encounter when reading mathematics texts.

## Reading mathematics text

This study concerns reading of mathematics tasks. It is therefore relevant that there exist features that are typical for mathematics texts, like special mathematical words (e.g., differentiate), words that have a different meaning in mathematical context than in everyday language (e.g., product), or the use of numbers and formulas (see, e.g., Schleppegrell, 2007). In this study, an assumption is therefore that reading and understanding a mathematical text requires a certain kind of reading ability that is part of the mathematical ability that a mathematics task intends to assess. But a mathematics task text can also contain features unconnected to mathematical ability, for instance, long or unusual “non-mathematical” words or complex sentences with subordinate clauses. These features might cause an unnecessary demand of reading ability that is unconnected to mathematical ability. In this case, a student needs, besides mathematical ability (including the aforementioned mathematics-specific reading ability), also a reading ability not connected to mathematics to solve the task. Therefore, it is important to separate necessary and unnecessary demands of reading ability of a mathematics task.

Österholm and Bergqvist (2012a) developed and confirmed the reliability and validity of the statistical measure for the unnecessary demand of reading ability (DRA) of a mathematics task used in this study. A principal component analysis of students’ results on both mathematics and reading tasks extracts two main and partly overlapping components; a mathematics and a reading component. Mathematics tasks are loading mostly on the mathematics component, but are also, to varying degree, loading on the reading component. The loading on the reading component excludes the effects from the overlap between the components, and can therefore be interpreted as a measure of DRA.

In a mathematics task that is supposed to measure mathematical ability only, DRA should be avoided as far as possible. To be able to avoid DRA, it is necessary to identify not only tasks with high DRA, but also which features of a mathematics task are related to high DRA.

## Sources of DRA

Since DRA measures a task's demand of reading ability that is not part of mathematical ability, it is plausible that linguistic features of the task text can be sources of DRA. These could be features connected to readability in general, such as long words (e.g., Lenzner, 2014), unfamiliar words (e.g., Abedi & Lord, 2001), or complex sentence structure (e.g., Dempster & Reddy, 2007). In an earlier study, Österholm and Bergqvist (2012b) found correlations between DRA and both word length and information density for the Swedish mathematics tasks of PISA 2003 and 2006. In a more recent study, Bergqvist, Theens, and Österholm (2018) identified tasks in the Swedish version of the PISA 2012 mathematics assessment having high DRA. In that study, however, the DRA was not correlated to any of the investigated features (word length, sentence length, task length, and information density). Identifying possible sources of DRA in mathematics tasks might help task constructors and teachers to avoid DRA or, at least, to make them aware of these issues.

## Purpose of the study

The purpose of this study is to deepen the understanding of the relation between features of the text of mathematics tasks and the tasks' demand of reading ability. Therefore, this study identifies and analyzes variations in students' reading processes when they work with PISA mathematics tasks with high demand of reading ability (DRA) and then relates these variations to the linguistic features of the task texts. Thus, the research question is: Which kinds of variations appear in students' process of reading Swedish mathematics PISA tasks with high DRA?

After having identified the variations, by examining the units of the text where they occurred, I attempt to identify and discuss which features of the text can be possible sources for the DRA

## Research Method

To investigate the variations in students' reading process, I collected and analyzed think-aloud-protocols (TAP) of students reading and solving mathematics PISA tasks in Swedish. These TAPs are part of a bigger data collection including students from both Sweden and Germany, several PISA-tasks, and follow-up interviews. In this study, I used the part of the TAPs where Swedish students read the tasks. The different steps of data collection and analysis are described in more detail below.

## Task selection

For this study, I chose two tasks from the Swedish version of the 2012 PISA assessment that were identified having high DRA in an earlier study (Bergqvist et al., 2018). Since these PISA-tasks are confidential they cannot be reproduced here. The two tasks differ in several properties: Task 800Q01 (Dataspel/Computer Game) is a single task without subtasks and contains relatively little text. It is a selected-response (multiple choice) task made up of two shorter sentences and a table with numbers. Task 446Q01 (Termometersyrsan/The Thermometer Cricket) is the first subtask of two in a longer task. It contains more text than 800Q01 - three long and two shorter sentences - and a photo showing the insect. It is a closed constructed-response item, that is, the students have to calculate an answer and write it down. They do not need to show their calculations.

## Selection of participants and data collection

The students were recruited from three different schools, two from rural areas and one from a bigger city. They voluntarily agreed to participate when their teachers asked the classes. All twelve students spoke Swedish fluently and gave their informed consent to take part in the study. Six students were working with task 446Q01 and seven students with task 800Q01. One of the students worked with both tasks. The eight girls and four boys were between 14 years and 6 months and 16 years and 1 month old, that is, about the age of 15, which is the age for which the PISA tasks are designed.

The students were told to read and think aloud during their attempt to solve the tasks. Everything the students said was recorded with a Livescribe Echo® smartpen, which also recorded everything the students wrote and connected it to the audio data. If the students were silent for a while they were encouraged to continue talking.

Think-aloud-protocols have the advantage that it is possible to follow the students' reading process and to get to know in which order they are reading the task text. Even if reading aloud is a somewhat unnatural way of reading mathematics tasks, it makes visible which words, phrases, or sentences may be problematic for the students, since oral reading fluency is an indicator for reading competence in general (Fuchs, Fuchs, Hosp, & Jenkins, 2001).

## Data analysis

To find the variations in students' reading process when solving the tasks, I performed an analysis in two steps. In step 1, I analyzed the TAPs to identify all variations and sorted them in different categories of types of variations. In step 2, I analyzed the categories found in step 1 to find patterns in the variations. The steps are described in more detail below.

Step 1: While listening to the TAPs, I made a note every time a student made any deviation from a "straight-on" reading process. This straight-on process is understood as starting to read at the beginning and reading all text once to the end without any interruptions. The straight-on process is not assumed to be an ideal way of reading, but used as a guiding norm to highlight variations. I also noticed if a student did not make any deviations from the straight-on process. Each time a variation occurred, I labeled it with a category. When this type of variation occurred for the first time, a new category was defined. When a variation of the same category had occurred before, this existing category was used. Examples for the categories are *stumbling*, *misreading*, or *rereading*.

Step 2: To get a clear picture of the nature of the categories of variations, I sorted the categories in two dimensions. The first dimension referred to which kind of unit of the text the category concerned. That is, whether the variations occurred at a single word, a phrase consisting of several words, or a whole clause or sentence. This division facilitated the identification of text features that might trigger variations in the reading process, since, for example, syntactic aspects of reading comprehension concern decoding at the sentence level, whereas phonological aspects concern word level. Some of the categories of variations can occur at several different units, for instance, a student could stumble at a single word or a longer phrase. For other categories, it is more difficult to determine which unit they concern. If a student, for example, makes a filler sound (like "er") in the beginning of a sentence, this variation could be categorized as being at word level (the first word of the sentence) or at sentence

level. In cases like this, I had to interpret within the context which unit the variation concerned, as described in the results paragraph below.

The second dimension referred to which aspect of reading the variation concerns. That is, whether it deals with the accuracy, the flow, or the order of reading. The accuracy of reading concerned what is read, that is, if the student reads exactly what is written in the text, or if he/she leaves out anything, reads anything wrong, or adds words to the text. The flow of reading concerned interruptions in the reading, for example, stumbling or hesitating. It also included repeating a word or phrase directly when reading it, which is a form of stammering. The order of reading concerned which order the student reads the text in, that is, if he/she starts at the beginning or, for example, by reading the question, and if he/she rereads any parts of the text.

## Results

The analysis of the think-aloud-protocols (TAPs) revealed several different categories of variations in students' reading process when solving mathematical PISA tasks with high DRA. A very common category was reading words and phrases correctly and with flow. On the other hand, there was only one student who read a whole task (Computer Game, 800Q01) straight-on, that is, read all text just once from beginning to end without any interruptions. In Table 1, the categories of variations that deviated from straight-on reading are sorted by the two dimensions mentioned above. Some of the categories are described in more detail below and exemplified in the discussion.

### Variations at word level

Many of the observed variations in the students' reading process were connected to a single word, like the ones categorized as *hesitating* or *stumbling*. Hesitating means that the student paused within a sentence before reading a certain word, interrupting the flow of reading. Stumbling also occurred in relation to phrases but the students mostly stumbled at single words, that is, they started to read the word, eventually read wrong, stopped in the middle of the word, and started over. Other types of variations concerning single words were *reading slowly* and different types of *misreading*. These variations occurred for example in task 800Q01 for the word “kriterium” (English: criterion) and in task 446Q01 for the words “snöträdssyrsan”, “termometersyrsan”, and “temperatursyrsan” (different names for the thermometer cricket), and “Fahrenheit”.

### Variations at sentence/clause level

At the sentence/clause level the observed variations concerned *rereading* or making *filler sounds* like “er” or “um” in the beginning of a sentence or clause. Filler sounds almost only occurred in the beginning of a sentence or clause and not within sentences. Therefore, this variation was categorized as sentence/clause level when occurring at the beginning of a sentence or clause.

There was no type of variation where the students changed the order of reading when they were reading the task for the first time. All students started reading the tasks at the beginning and read them until the end, that is, none of them started by reading the question written in the end. For task 446Q01, all students but one reread some part of the text task at some point after having read the complete text first — either before or after having solved the task, or both. For task 800Q01, four of seven students who worked on the task did not reread any clause or sentence of the task text.

	Word	Phrase	Sentence/clause
Accuracy of reading	<ul style="list-style-type: none"> <li>· misreading, becomes a different word</li> <li>· misreading, becomes meaningless</li> <li>· misreading, becomes a synonym</li> <li>· misreading a number</li> <li>· skipping a word</li> <li>· adding a word</li> <li>· wrong pronunciation</li> <li>· mumbling</li> </ul>	<ul style="list-style-type: none"> <li>· mumbling</li> </ul>	
Flow of reading	<ul style="list-style-type: none"> <li>· hesitating</li> <li>· filler sounds</li> <li>· stumbling</li> <li>· pausing within a word</li> <li>· reading slowly</li> <li>· repeating</li> </ul>	<ul style="list-style-type: none"> <li>· stumbling</li> <li>· repeating</li> </ul>	<ul style="list-style-type: none"> <li>· filler sounds</li> </ul>
Order of reading			<ul style="list-style-type: none"> <li>· rereading after having read everything</li> <li>· rereading after having solved the task</li> </ul>

**Table 1: Categories of variations in the students' reading process deviating from straight-on reading**

## Discussion

Some of the observed variations in students' reading processes may indicate problems for the students when reading the tasks' text. These reading problems can relate to different aspects of reading comprehension (phonological, semantic, or syntactic) depending on features of the word, phrase, or sentence/clause that was problematic. In this section, I discuss some of the variations that may indicate sources of unnecessary demand of reading ability (DRA).

### Variations at word level

Several types of variations occurred in relation to the different Swedish words for “the thermometer cricket” (“snöträdssyrsan”, “termometersyrsan”, “temperatursyrsan”) in task 446Q01. Some students were stumbling or hesitating when reading these words. These expressions are long compounds of shorter and more common words such as “snö” (English: snow) or “syrsan” (cricket), which can make it difficult for the students when they read them for the first time. Since the observed categories of variations concern decoding of written text into sound, they relate to the phonological aspect of reading comprehension (Hoover & Gough, 1990; Perfetti et al., 2005). Two other types of variation occurring for these words are related to semantic aspects of reading comprehension, since they refer to the meaning of the words. One type of variation was that some students read “...syran” (acid) instead of “...syrsan” (cricket) the first time they read the word. A possible explanation is that reading the context and seeing the photo of the cricket eventually helped them realize that the text was about an

insect, and they did not make this mistake any more. The other type of variation was that some students read simply “syrsan” (cricket) instead of “thermometersyrsan” (thermometer cricket) when they reread the sentences. A possible explanation is that they had understood that the text was about some kind of cricket and realized that the exact name was less important. Since DRA for a task concerns a demand of reading ability that is not part of mathematical ability, and since knowing and reading these names for the cricket cannot be seen as a part of mathematical competence, the use of these long compound words in this task may be a source of high DRA.

Another word in task 446Q01 where the variations *hesitating*, *stumbling*, and *reading slowly* occurred was “Fahrenheit”. For Swedish students, this is not a common word in their everyday language since temperature is measured in degrees Celsius in Sweden. The use of different units can be seen as being a part of mathematical language and, thus, a part of mathematical competence. In this case, the use of “Fahrenheit” is not likely to be connected to high DRA, since DRA concerns the part of reading ability that is *not* included in mathematical ability. In task 800Q01, some students were hesitating and reading slowly the word “kriterium” (English: criterion). This is a shorter word than, for example, “snöträdssyrssan” but not a compound of shorter common words and not common in the students’ everyday language either. Since it does not belong to the vocabulary that is necessary or common when communicating mathematics at these students’ school level (year 8-9), it might contribute to DRA of the task.

### **Variations at sentence/clause level**

At the sentence/clause level, one variation was that students reread sentences or clauses after having read the whole text first. At task 446Q01, this occurred most frequently at sentence 3, which was a long sentence presenting the way to calculate. It also occurred at sentences 4 and 5, where the question was posed, but never at sentence 1 and 2 that contained general information about the cricket. At task 800Q01, it occurred mostly for sentence 2 that contained the question and more seldom for the first sentence that presented the situation. The same pattern occurred when students were reading sentences or clauses again after having solved the task. I see two aspects as possible explanations for this, either individually or in combination of both. After having read the text once, it is possible that the students had figured out in which sentences the information necessary to solve the task was presented. Based on this conclusion, they could have deemed it unnecessary to reread, for example, the first two sentences in task 446Q01, since these only presented general information about the cricket. This behavior would be an indication that the students mastered the semantic aspect of reading comprehension, which refers to meaning (Nation, 2005).

Another possible explanation for these variations, in particular the common rereading of sentence three in task 446Q01, can be syntactic issues. This sentence is long (37 words) and contains three subordinate clauses. Such sentence complexity could cause DRA, that is, a demand of reading ability, not connected to mathematical competence.

### **Conclusions**

This study has shown that there are different kinds of variations in students’ process of reading when they are working with mathematics tasks that have a high demand of reading ability (DRA) not connected to mathematical ability. These variations occur both at single words, longer phrases, and whole

sentences and may be of different types. Some of the variations, such as stumbling or hesitating, can indicate reading problems that the students encounter. In this study, I found some examples in the two tasks investigated that may be related to these issues. Further research with more students and tasks can help to identify more text features that may cause DRA.

# Generalizing distributive structures in primary school

Annika Umierski and Kerstin Tiedemann

Bielefeld University, Germany; annika.umierski@uni-bielefeld.de

*In the reported project, the focus is put on the process of generalizing distributive structures: How do primary school children use different communicative resources in order to express their generalizations? Thereby, the use and function of language is of particular importance. When analyzing the interview data, the central questions are: How does the interplay of different resources vary? What does that consequently mean for the level of generalization? In this paper, we present first results from a pilot study. They suggest, among other things, that language and manipulatives can fulfill quite contrasting functions when they are used in combination.*

*Keywords: Generalizing, distributive structures, resources, language.*

## Introduction

“Generalization is the heartbeat of mathematics, and appears in many forms” (Mason, 1996, p. 65). According to Mason (1996), generalizing can be described as one of the basic skills in mathematics. The ability to notice a local commonality in patterns or terms and to distinguish between different aspects (Radford, 2006) enables learners to generalize this across all terms. Then this identified generality can be used as a basis to develop strategies (Lannin, 2005).

It becomes apparent that generalizing is not only important from a propaedeutic point of view, but is already important in primary school itself. In accordance with Lannin (2005), in some contexts using a strategy means using a general rule, for example generalized distributive structures can be used to derive multiplication tasks. Therefore, instead of investigating generalizations of patterns, like it is commonly done, this study will focus on how primary school children generalize distributive structures. In primary school, different resources, such as images or mathematical signs, are available. Primary school children can use these resources for generalizing as well. Language as one resource stands out, because it enables students to detach from concrete objects and to make mathematical structures visible (Radford, 2003). Moreover, if students can express complex structures in a more condensed way with language, it indicates a bigger availability of those structures (Caspi & Sfard, 2012). Therefore, the way how structures are expressed with language can be used as an estimation of the level of generality (Caspi & Sfard, 2012). This is why - concerning generalization - language seems to be an important aspect. Hence, the interplay between language and other resources and its function and role are to be investigated in this study.

In this paper, at first generalizing is defined, the meaning of generalizing in context of distributive structures and the students usage of combinations of resources are outlined. According to the current theoretical framework, our research interest and results of the pilot study are presented.

## Theoretical framework

### Generalizing in mathematics

Generalizing as a process consists of multiple parts with different focuses. Hence, the term generalization is not used consistently. Nevertheless, most definitions refer to the ability of “seeing a generality through the particular” (Mason, 1996, p. 65). When generalizing, commonalities across different cases have to be identified and regularities have to be derived and extended to other cases (Ellis, 2007; Fischer, Hefendehl-Hebeker, & Prediger, 2010; Harel & Tall, 1991)

The biggest difference between the definitions is the prioritization within the process of generalizing. While Harel and Tall (1991) emphasize that in generalizing the scope of a mathematical object is extended and transmitted, Fischer et al. (2010) highlight the understanding of commonalities in a general context. Furthermore, Ellis (2007) distinguishes between generalizing *actions* and *reflections*. On the contrary, Radford (2003, 2006) distinguishes between the *comprehension* and the *expression* of a generality. The formal way in which generalizations are expressed is not overly important for Ellis, while it is crucial for Radford. Nonetheless, for both researchers the grasping of a general structure is the first step of generalizing. Average primary school children are not able to refer to algebraic language such as variables (Britt & Irwin, 2008). This is why the focus on how primary school children expressing generalizations, becomes especially interesting.

Students can use different ways to express a generalization, for example gestures or colloquial means (Radford, 2003). According to Radford (2003, p. 65) “language allowed the students to carve and give shape to an experience out of which new general objects emerged”. Additional resources, like manipulatives, are available in primary schools. Usage of and switching between representations, which can be used as resources (Greeno & Hall, 1997), support the development of mathematical understanding (Duval, 2006). The expressions themselves may differ in their degree of generality. In particular, the usage of language to express a generality can indicate the level of generality (Caspi & Sfard, 2012). According to that, three levels can be claimed within the process of generalizing. At the first level, *processual description*, language is used to express and describe a calculation. The calculation is presented in the order of its execution. Generalizations at the second level, *granular description*, still include description of a process but also (linguistic) parts that transform procedural elements into an object, like ‘the product of...’. This change from an operational conception (process) to a structural conception (object) is called reification (Sfard, 2008). At the third level, *objectified description*, all processes are reified and students use them as fully fledged objects, for example ‘if two products have a common divider, they can be combined into one fact’. General expressions “will now be used in alienated (depersonalized) descriptions of relations between objects” (Caspi & Sfard, 2012, p. 51).

While Radford (2003) emphasizes the importance of natural language, Caspi and Sfard (2012) focus on the meaning and level of generality of language and Duval (2006) classifies language as one of four equally important representations. With the help of these different perspectives on language, various expressions and the associated interplay of different resources and its consequences for generalization are to be investigated.

## Generalizing distributive structures

It should be noted that many studies refer to the generalizations of pattern sequences (Akinwumni, 2012; Blanton & Kaput, 2005). However, Ellis, Lockwood, Moore, and Tillema (2017, p. 677) are correct to point out, that “there remains a need to understand how students construct generality in more varied and more advanced mathematical domains”. Our interview study aims to investigate how primary school children express their generalizations of distributive structures. Since generalizing as a form of algebraic thinking represents a general capability, results from previous studies serve as a first empirical basis and should be compared with results of this study.

The skillful use of arithmetic laws supports students to develop strategies for solving arithmetic problems (Lannin, 2005). In order to be able to use arithmetic laws skillfully, students have to grasp structures in concrete tasks and generalize them. Only if general regularities are extended beyond a case (Harel & Tall, 1991), they can be related to other contexts and used to the student’s advantage. According to Mason (1996), generalizing can be described as the identification of a general rule through particular tasks. This generalized rule in combination with fact based knowledge can serve as a strategic tool. Therefore, in the context of multiplication, generalizing means the recognition of the systematic construction of multiplication and the classification of separated facts in its construction.

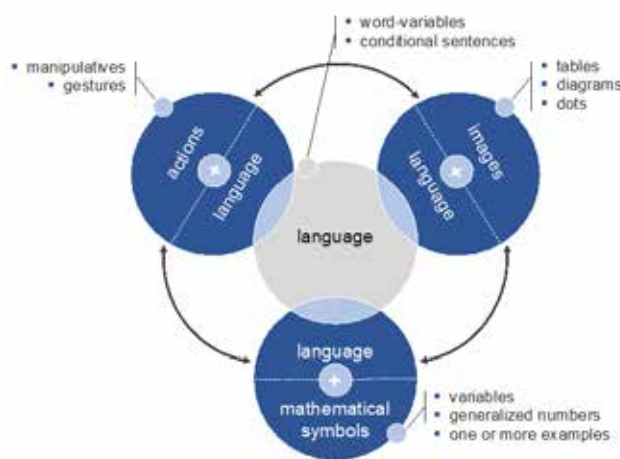

In primary school, the distributive law is often implicitly used. Primary school children do not learn to automate multiplication task by learning the times table off by heart. Instead they learn to acquire an understanding of the multiplicative operation and to automate facts that are easier to remember in order to derive facts that are more difficult to remember (Gaidoschik, 2016). Students do not have to acquire and automate all 100 multiplication facts, merely the facts of the one, two, five and ten times tables. If students have insights into distributivity, they can systematically derive all further facts of multiplication (Gaidoschik, 2016). Therefore, individual cases do not always have to be treated as new phenomena but are assigned to a certain structure, so that the memory of students who automated a lot of structures is much less stressed (Fischer et al., 2010). In summary, from this perspective the use of deriving strategies includes a form of generalization of distributive structures.

## Expressing generalizations: Language and other used resources

According to Radford similarities and differences of structures are grasped and expressed through and with linguistic expressions (2003, 2006). Language is particularly suitable in this process, because it turns experience into knowledge (Halliday, 1993). “With [...] speech, words become signs capable of being used with a certain autonomy regarding the objects they denote” (Radford, 2003, p. 63). Since generalizing means to abstract from the particular to the general (Mason, 1996), language is particularly suitable as a resource. Therefore, it is assumed that regardless of its level or function, language takes part in expressing generality.

However, language is assumed to be especially challenging for some students (Fetzer & Tiedemann, 2015) and in primary school students use other resources, such as manipulatives, in addition to language to acquire and communicate mathematical understanding. Therefore, instructions “should include how students use the situation, the everyday register, and their first language as resources as well as how they make comparisons [...] and use mathematical representations” (Moschkovich, 2002,

p. 208). In this study, the term *resource* refers to all representations, such as language or manipulatives, which students can use in order to express generalizations. Figure 1 provides an overview of these possibly used resources. The structure of the figure is based on the distinction between different representations (e.g., Duval, 2006) and the assumption that language always plays a role in generalization. Therefore, a distinction is made between three different types of combinations of representation *language and mathematical signs*, *language and actions* and *language and images* and the representation *language*. These (combinations of) representations are available resources that can potentially be used for generalizing. In previous studies, particular resources are identified as appropriate for the process of generalizing (Akinwumni, 2012; Britt & Irwin, 2008) are consequently relevant for our study, too. These resources have been assigned to the combinations of representations (Figure 1).

**Figure 1: Combinations of resources in generalizing**

As figure 1 shows, it is assumed that resources are not used separately but mutually in relation to each other. Language can have different functions within these combinations. While the use of language in form of word-variables can refer to grasped structures, *reified objects* as Sfard (2008) calls them, language can serve to describe generalized numbers (Akinwumni, 2012), relations and other resources as well. In conclusion, language has a functional character for all available resources and the interplay within the combinations can vary according to the individual use. Moreover, the switch between two or more combinations of representations, like *language and actions* and *language and mathematical signs* is possible as well. According to Duval (2006), the process of switching between different representations reveals whether a given mathematical structure has been understood. Thus, generalizing can be understood as a form of understanding: A child that is expressing a given structure in two different representations, in this context two different combinations of representations, is generalizing this particular structure. Moreover, “forms of representations are *tools* that students can learn to use as resources in thinking and communicating” (Greeno & Hall, 1997, p. 362). Therefore, various resources should be made available for primary school children should be used.

### Research interest

According to the theoretical assumptions, we are looking for answers to the following questions: (How) do children use language in order to generalize distributive structures? And can language, as a consequence, be regarded as the essential resource for the purpose of expressing generality? Correspondingly, we want to learn more about language and other used resources of the children while generalizing distributive structures. This focus touches two aspects, the interplay within the combinations of resources on an interactional level and the switch between different combinations and its respective consequences on a content level. To describe the use of resources and combinations, we refer to children’s multi-resource statements and at first focus on the following two questions:

- How do students use different combinations of resources in the process of generalizing?
- How do two resources interplay within a combination in the context of generalizing?

## Research design

Our study is designed as an interview study. In order to pursue the research interest, the interview questions and tasks are in accordance with the classification (see Figure 1) of the interplay within and between the combinations of resources. It refers to the assumption that language always takes a part

**Figure 2: Multiplication blocks**

and its function is determined in relation to other resources. Based on a guideline, children are asked to decide whether they can identify a distributive structure in different resources. In this paper, the use of one resource, the multiplication blocks, is presented as an example. Those blocks are manipulatives like given blocks that are composed of different amounts of cubes (see Figure 2). These blocks are fixed, glued together wooden cubes, which cannot be attached but laid against each other.

Therefore, the interviews are designed according to the different resources. In addition, the interview differentiates between the two “directions” of the distributive law: One interview part focuses on decomposing one multiplication fact and the other interview part focuses on combining two multiplication facts. Within the part of combining, two different types of tasks serve as basis. In the first type of task, two multiplication facts may be combined to one multiplication fact, e.g.  $2 \times 3 + 3 \times 3 = 5 \times 3$ . In the second type of task two multiplication facts cannot be combined to one multiplication fact, e.g.  $2 \times 3$  and  $1 \times 4$ . Table 1 illustrates an extract of the second type of task of the pilot study guideline. In order to emphasize the relation to the mathematical context of the distributive law, a section of the interview talks about concrete facts in the form of mathematical symbols. The relation to mathematics is also established by naming the blocks according to their respective facts.

Resource	Questions	Research interest
 2x3-block    1x4-block <hr/>  2x4-block	<ul style="list-style-type: none"> <li>• Can you combine these two facts to one fact?</li> <li>• Why yes or no?</li> <li>• And what about this fact? Why can I now combine two facts?</li> </ul>	<ul style="list-style-type: none"> <li>• What aspects are the learners focusing on?</li> <li>• How and with which resources do they generalize? How do these interplay?</li> <li>• Does the generalization change?</li> <li>• How do they talk about the new situation?</li> </ul>

**Table 1: Interview guideline and associated research interest**

The interview is conducted with second- and third-grade students of different primary schools. One of the schools is supposed to be a language school, a school for children with language disorders. These two types are chosen because, on the one hand, the difference between children with and without language disorders should be emphasized. On the other hand, the difficulties of children with language disorders may point to general aspects of the relation between language and generalizing.

In order to reconstruct the processes of generalizing distributive structures, we transcribe the recorded interviews and subsequently use the analysis of interaction (Cobb & Bauersfeld, 1995). This method serves to reconstruct the processes of negotiation between the child and the interviewer and reveals the content-related ideas which emerge in the interaction. This allows us to determine levels of generalization (Caspi & Sfard, 2012) with a special focus on the interplay of resources.

## First results

To give an impression of the results from our pilot study, some illustrative examples are presented in the following. In May 2018, six second-grade students of a primary school for children with language disorders, were interviewed. Reference was made only to the combination of *action (blocks) and language*. First results indicate that depending on the type of task (two multiplication facts can be linked distributively or not), students generalize on different levels. According to Caspi and Sfard (2012) *generalizing is distinguished regarding to the level of generality*. In tasks of the first type students used language to generalize in form of chronological description, for example: “first there was  $3 \times 3$ , then  $2 \times 3$  was added and then it is  $5 \times 3$ ”. Relating to Caspi and Sfard (2012), these descriptions comply with the first level *processual description*. On contrary during completion of the second type of task, students used vocabulary like “here is always one more” or “because now this has two and this has two, too”. These terms correspond to the second level *granular description*. Parts of their generalizations such as the “two” are objectified, as it stands for the second times table and hereby for the general distributive structure. In conclusion, the two types of tasks could be used to induce various level of generality when generalizing distributive structures.

Further results can be seen when *generalizing is distinguished regarding to its expressions* (following Radford 2003, 2006). According to the theoretical framework of resources, the interplay of resources have been analyzed. The participating children with language disorders used the offered manipulative combined with language. Their generalizations were quite often grammatically incomplete and incorrect. In addition, they tended to use gestures and linguistic references, such as pronouns like “it does not fit, here ( $1 \times 4$ -block), to that ( $2 \times 3$ -block) two more”. In this example, the student compensated missing language with the help of provided material and used place deictic words. According to Fetzer and Tiedemann (2015), manipulatives are used to relief language. Thus, the scope how to interpret the expression extents. At this point it is assumed that the manipulatives function as generic example, because the example is used to explain conditions of a general structure (Harel & Tall, 1991). The function of language is to emphasize the aspect that is being referred to.

Similar interviews were conducted at another primary school with no particular specialization on children with language disorders. These students used considerably more nouns, conditional sentences, and explained their processes in a more detailed way. The example “this stone (single cube of  $1 \times 4$ -block) must go, then we would have  $3 \times 3$ ” shows a combination of manipulative and language as well, but the manipulative does not relief language. Language is used to structure the process and to construct an example, which includes parts of a generic example, such as the use of a conditional statement. The use of language makes it possible to construct relations that are not visible. Nevertheless, the description is close to the concrete example, like “must go”. Because of this, the utterance is interpreted as an example with the potential to be generalized.

The comparison between both participating student groups indicate a difference in expressing generalizations of distributive structures. Both examples refer to the same mathematical content and in both cases a *granular description* (Caspi & Sfard, 2012) is given. Both children describe a process combined with facts ( $2 \times 3$ ,  $3 \times 3$ ), which are used as reified objects (Sfard, 2008). Furthermore, the same resources are involved. However, the interplay within the combination of the resources *language* and *manipulative* differs. Two different types of resource interplay in the process of generalizing have been identified. While in the first example the manipulative enriches the linguistic expression, linguistic expressions enrich the manipulative in the second example. Consequently, we can see that children express comparable generalizations by using resources differently.

## Outlook

These first results indicate different functions of language in the process of generalizing. According to the interplay of resources, it further will be analyzed how the other resources (images and mathematical signs) interplay with language. To figure out how language and the other resources interplay in detail and its consequences for generalizations is one of the main goals of the further research project. In addition, the objective of the study is to analyze how an interviewer or another child interprets expressions within an interaction. Both examples provide potential that can be identified as generalization. Regarding to the two different types of resource interplay, it will be worked out how expressions will be grasped and how the types influence the generalization of distributive structures. In addition to the resources, it will be investigated, how and if the consequences through the two types of tasks can be confirmed and which conclusions arise regarding generalizing. The analysis of the pilot study also shows that new impulses must be developed to facilitate generalization. For example, we should no longer talk about concrete facts, but about a rule.

### Scope and Focus

Thematic working group 10 is interested in discussing mathematics education within the realms of *culture, society and the political*. TWG10 builds on the premise that mathematics education is always more than the encounter between an individual and an object. Such encounters are embedded within wider contexts than just classroom settings. They are shaped by the social, cultural and political contexts in which they take place. Being social, cultural and political encounters themselves, they reflexively contribute to constituting the wider context in which they are embedded. Research in this group is characterized by an effort to reflect its own double-role in not only analysing but also shaping the possibilities of seeing and inventing mathematics education practices.

The call for papers invited participants to address how *diversity* affects possibilities in mathematics education. The group's work was based on a broad understanding of diversity, including: 1) Diversity as expressed in terms of attributes of people, such as gender, ethnicity, language, socio-economic status, social class, (dis)abilities, needs, achievement, life opportunities; 2) diversity as expressed in terms of ways of perceiving the world and giving structure to it, such as aspirations, worldviews, ideologies, school systems, and governance structures; 3) diversity in relation to the variety of sites where mathematics education takes place, such as schools, homes, workplaces, after-school organisations, communities; and finally, 4) diversity in relation to who is doing the research and who is being researched, posing methodological issues of an ethical nature. Diversity thus also refers to the wide variety of doing mathematics education research within the realms of culture, society and the political. As all these multiple diversities intersect, the group made an effort to develop reflexive approaches. The group invited to explore, deconstruct and even reinvent the concept of diversity.

### Organisation of TWG 10's work

Understanding research as a practice that is situated within the realm of the cultural, the social, and the political has implications for practicing research *in situ*. We strived to organize the group to work in a way that 1) cultivates a change of perspectives and fosters reflexivity and 2) creates consciousness about the power relations underlying TWG10's work as a community of practice. The introduction in the first session gave a brief overview about the controversies that have unfolded within the TWG in previous CERMEs, highlighting that controversies do not only occur *between* (groups of) scholars but also occur *within* individuals or within allegedly homogeneous "camps". Fostering controversy was intended to counteract dichotomization and facilitate the deconstruction of binaries.

The development of reflexivity was sought by following the principle of *peer presentation*, namely that authors do not present their own paper, but give a short (5 minutes) presentation of a colleague's paper. This peer presentation included a description of the main ideas from the perspectives adopted in the paper and the formulation of questions from the presenter's own perspective that opened up subsequent whole-group discussion (15 minutes). In addition, two sessions each involved, firstly, a small group breakout discussion (30 minutes) and, secondly, a synthesis (30 minutes) to support participants in drawing connections between contributions. In an attempt to make poster contributions visible to the whole group, posters were also presented. However, since the poster presentations were not followed by discussions, this procedure did not only make visible the posters, but also visualized and potentially stabilized the hierarchical distinction between papers and posters.

## The papers discussed

In order to encourage and also facilitate drawing connections between papers, they were grouped in thematic pairs before the conference. As any classification does, this grouping highlighted some connections while displacing others. In the 1<sup>st</sup> session the contributions of *Wright* and *Black et al.* critically sounded out possibilities of practicing progressive pedagogy in favour of underprivileged students. In the thematic pair on democratic experiences, *Daher* sought for ways of assessing democratic practices using a quantitative analysis of questionnaires, and *Sachdeva* took a closer look on how students experience learner autonomy in mathematics classes. In the first half of the 2<sup>nd</sup> session, *Maheux et al.* invited us to consider school mathematics as a possible reference for mathematics itself, hence disrupting traditional understandings of mathematics, where professional mathematics is often seen as the reference for school mathematics. *Salazar* reported on how students of colour developed a practice of mathematics in problem solving activities similar to the practice of professional mathematicians, thereby disrupting institutional racism in traditional school mathematics. In the second half of the session, *Cabral et al.* proposed Solidarity Assimilation Methodology not only as a way of disrupting traditional pedagogy, but also as a way of subverting the recurrent mode of capital accumulation embodied in assessment practices. *Bagger et al.* analysed how a neoliberal regime of assessment has expanded into the domain of preschool-class education in the Swedish context. The first half of the 3<sup>rd</sup> session was devoted to the connections between mathematics and life. *Aizikovitsh-Udi* reported on a teaching unit that aimed at explicitly teaching critical thinking skills. *Yolçu* problematized the forms of responsabilisation, reason and rationality in a course on “mathematical applications” in Turkey. In the second half, the contributions of *Kollosche* and of *Lüssenhop et al.* focused on language diversity, the former proposing guidelines for analysing and developing teaching materials, the latter exploring the practices of teachers in international preparatory classes for refugees. In the 4<sup>th</sup> session, *Makramalla et al.* explored the gaps between the “mathematical ideologies” of the Egyptian curriculum, of the teachers and of the teachers' practices, yielding the potential for change within the contextual power dynamics operating in Egypt. *Foyin* confronted an emerging public discourse in Norway on disadvantaging boys with data from a longitudinal study, highlighting the need to nuance the debate and not lose track of the discourses that still disadvantage girls. Critically reflecting the power relations between the researcher and her/his informants, *Lembrer* raised methodological questions concerning the use of photo-elicitation for data-collection in the context of early years mathematics education. *Kara et al.* presented their research on the relation between students' social backgrounds and their problem-solving competencies. *Nordkild et al.* reported on a culturally sensitive teaching unit in Finland. The unit was developed by students

with a Sami background to teach geometry to peers from their own culture. The first half of the 5<sup>th</sup> session was devoted to mathematics teacher education. *Povey* reflected on the potential of her own teaching practice as an embodied case of a “living education theory” to serve the aims of social justice. *Dexel et al.* showed how a course on inclusive mathematics teaching for pre-service teachers fostered a potential-related perspective on diversity within teacher-students. This potential-related perspective on diversity was further developed in the second half by *Padilla et al.* who proposed the conjunction of interdisciplinarity, culturally sustaining pedagogies and pandisability cultures as a point of departure for co-creating diverse mathematics learning contexts. The need for such co-creation was empirically consolidated by *Nieminen* who reconstructed discourses of otherness in self-reports of university students with special needs. The 6<sup>th</sup> session zoomed in on the mathematics student. Both the contributions of *Røj-Lindberg et al.* and *Doğan* reconstructed students’ perspectives. The former did so through a longitudinal study that provided insight into why some students develop negative identifications with mathematics despite the reform-related efforts of their teachers. The latter turned the focus on a popular Turkish social medium, where almost a thousand users reported on their moments of farewell to mathematics and constructed it as an individual and subject-related fate. The last thematic pair focused on students’ identities. Taking an intersectional approach, *Sabbah et al.* investigated how categories of gender, ethnicity and religion play out in the formation of agency and identity in female Arab students entering university mathematics in Israel. *Gebremichael* explored in an Ethiopian context how students perceive the relevance of mathematics and how this is closely linked to the development of identity. His analysis also sheds light on how little Ethiopian mathematics education is attuned to Ethiopian society’s needs and the possible historical reasons for this.

## Common conclusions

All contributions and discussions were characterized by a strong openness to perspectives and methods that are not yet established within the field of mathematics education, but belong to the state of the art in the corresponding disciplines of reference. This interdisciplinary character was consistently appreciated. It also led participants to collectively question the “nature” of mathematics: How do we define it? What are legitimate sources of reference? Who decides what is legitimate? The group agreed that these questions must remain undecided. Another issue that found unrestricted approval was the necessity of bringing theory and practice together, not only rejecting theory for theory’s sake but in a similar manner rejecting excessively inductive empirical research. This commitment to (social) theory is related to the critical spirit that participants saw as common ground, binding the group together. Work in this group is largely concerned with a critique of the *status quo*. This critique may concern educational institutions or the societies we live in more broadly. Group members were united in the desire to change systems, whilst at the same time being aware that they are part of these systems themselves. This insight resulted in a self-critical attitude when it comes to assessing the ethical ramifications and also the generalisability of research. The self-critical attitude expressed itself in the fact that participants consensually cherished TWG work as an opportunity of “decentring oneself”, an opportunity to experience their own perspective as one among legitimate alternatives, thereby allowing a reflection about each perspective’s social, cultural, and political foundations. It was also expressed in a deep concern for the power relations that pervade instances of mathematics learning and teaching as well as research practice and the dynamics within the working group itself.

## Open questions / controversy

While the participants all agreed on conceptualizing power as simultaneously having both restricting “negative” as well as empowering “positive” effects, the group remained undecided about the normative ramifications related to identifying power relations. For example, the group addressed the question of whether there is a boundary between acceptable and unacceptable values. What would a strictly horizontal organisation of values imply? If we do not privilege some values over others, how can we, then, talk back to and fight against socially accepted forms of oppression and violence? Related to the question of equality of values is the question about the role and function that we assign to schools: Is it their task to adapt to students’ backgrounds? Or is it exactly their task to treat students irrespective of their background, or at least help them to transcend their backgrounds? Reflecting the political and moral underpinnings of each of the participants’ stance certainly created tensions within the group. Some participants may identify with dissolving tensions to one side or the other, a third part of participants may identify with the contradiction inherent in the tension itself. While the group agrees that it is a collective task to deal with these contradictions and tensions, there may be different normative stances on how this *should* be done: Once power relations within the group surface, should the use of power be regulated? Can the group benefit in the future from explicit rules so that “privileged” participants develop techniques to govern themselves, re-distributing power to the “non-privileged”? Or would this suffocate the attempt to embrace controversy, finally leading to synchronization of perspectives and thereby jeopardizing the cherished opportunity of decentring oneself? Another controversial issue was the role of utopia in our research: Is utopia the generator of change that allows us to think of something in rupture with what exists? Or is utopia actually preventing change to materialize by outsourcing change into some displaced “alternative reality”? Finally, identifying all these controversies led to commonly posing the question: How much diversity can a thematic working group on “diversity” productively handle?

## Future tasks

The group identified a need to ensure the productivity of diversity and saw the danger of losing depth in the discussion. Depth, here, applies both to the scientific quality as well as to the social quality of mutual intellectual engagement. Two ideas that found approval were 1) the reformulation and specification of the group’s theme and 2) a stronger focusing and specification of the group’s call for papers. Concerning the theme, the group agreed that even though *diversity* adequately described the spirit of the group, it factually did not serve anymore as the thematic pivot. It is a designated task for the future TWG-leaders to maintain this spirit of diversity. However, the contributions rarely addressed diversity explicitly. The group suggested to exclude diversity *from the title*, nevertheless making sure that the call maintains the thematic inclusion of diversity *as a theme* (among others). Further, the call should more explicitly demand authors to interrelate “the micro” and “the macro” which also implies a stronger attentiveness to social, cultural and political theory. If the next group-leaders should, however, decide to keep diversity in the title, there is a need to sharpen the call for papers in that direction. In order to develop in any of these directions, the group requires a clearer and more concise focus in order to maintain its scientific and intellectual productivity.

# Construction of Critical Thinking Skills by the infusion approach in “Probability and Statistics in Daily Life”

Einav Aizikovitsh-Udi

Davidson Institute, Weizmann Institute of Science, Israel; [einav.aizikovitsh@weizmann.ac.il](mailto:einav.aizikovitsh@weizmann.ac.il)

*This paper presents a teaching experiment that combined the explicit teaching of critical thinking with the content of an existing mathematics unit called “Probability and Statistics in Daily Life”. The original unit was designed to teach probability and statistics through real-life scenarios at the high-school level. I took the original mathematical content and “infused” it with a progression of critical thinking skills, so that both the mathematics and the critical thinking competencies developed hierarchically, growing more and more complex as the unit progressed. This paper illustrates the mutual benefits of this “infusion” to both the teaching of statistics and of critical thinking. The paper discusses the problem of transfer of critical thinking skills and shows some promising elements in that sense, deriving from the analysis. Finally, it also discusses some educational implications of the work done, the limitations of the unit’s first run and the improvements that may yet be made.*

**Keywords:** Critical thinking, probability, statistics in daily life.

## Introduction

This paper reports a research project undertaken into the utilisation of the mathematics classroom for the specific development of critical thinking skills through probability instruction (Aizikovitsh-Udi, 2012). In this paper, critical thinking skills are taken as representative of the aspirations of the majority of mathematics curricula. I suggest that the mathematics education community needs to investigate why the consensus regarding the importance of higher order thinking skills in mathematics has not led to greater consistency and success in its classroom implementation. This research represents one attempt to give classroom reality to this curricular aspiration and examined the processes of construction of critical thinking skills (e.g., identifying variables, suspension of judgment, referring to sources, searching for alternatives) during the study of the “Probability in Daily Life” learning unit in an infusion approach. In particular, I closely reviewed the contents of the learning unit for connection to relevant thinking skills. The skills that were found relevant were: (a) identifying variables; (b) referring to sources; (c) identifying assumptions; (d) evaluation of statements; (e) suspending judgment; (f) offering alternatives.

## Theoretical Background

The term “critical thinking” (CT) has been used in academic circles for less than a century, but evidence of the relevance of this concept in education is far older, spanning several forms of human endeavor and 2500 years of human history since the Greek Antique. The universal applicability of these “ancient” skills is perhaps more relevant than ever in today’s complex and ceaselessly changing reality, which requires independent decision-making on a daily basis. Fostering and developing students’ ability to think critically, to be capable of engaging in inquiry and evaluation based on rational considerations regarding the various messages they are exposed to in different areas of life, is therefore a particularly important part of their education (Bryan, 1987; Feuerstein, 2002; Glaser,

1972). While this need to focus on the promotion of CT skills has long been widely recognized by educators (Ku, 2009), they have not yet reached a similar consensus regarding *how best this should be done*. This on-going debate raises the question of whether critical thinking should be taught as a topic in its own right, or integrated into a topic already present in the school curriculum. This question in turn raises additional questions – for instance, if critical thinking *is* integrated, which subjects should it be integrated with? Furthermore, when teaching CT skills in conjunction with another topic, should these skills be taught *implicitly*, as a hidden component ‘immersed’ in the primary material, or should they be an *explicit* part of the learning experience, in which the students’ attention is drawn to their presence as an additional component ‘infused’ into the material through which it is being taught?

Amongst those who believe that critical thinking should be taught in conjunction with other subjects, one of the topics suggested for this purpose is mathematics. In the field of education, mathematics has traditionally been considered a branch of knowledge particularly suited to the teaching and learning of higher-order thinking skills such as critical thinking. Mathematics curricula all over the world, including Israel, identify the acquisition of these skills as one of their goals. The idea that mathematics is a discipline suited to teaching critical thinking also appears in the research literature in a more or less explicit way (Elder & Paul, 1994; Paul, Elder, & Bartell, 1997).

However, in spite of this assumption, very few empirical studies to date have engaged with the question of whether the study of school mathematics indeed develops or even requires this mode of thinking. The answer to this question is far from being clear. The study upon which this paper is based attempts an approach to teaching critical thinking through mathematics that *explicitly* integrates the topic into a learning unit designed to teach high-school level probability and statistics. This topic is, I believe, particularly well-suited for the acquisition and practical application of critical thinking skills. Our model is based on the combination of two theoretical elements: the hierarchical model of critical thinking skills presented in Ennis’ (1985, 1987a, 1987b) taxonomy and the “infusion approach” to teaching posited by Swartz & Parks (1994). To create the new learning unit, whose classroom implementation is presented in this paper, I took the mathematical content of an existing learning unit called “Probability and Statistics in Daily Life” (Lieberman & Tversky, 2001) and (in collaboration with one of this unit’s co-creators) I “infused” it with a hierarchical progression of critical thinking skills according to Ennis’ taxonomy (Ennis, 2002). In this paper, I present, in order of increasing complexity, a series of three samples from the classroom implementation of the unit. These illustrate a) how the two topics develop hierarchically together, and b) how each lesson combines them anew, calling on the students to draw on both their mathematical and their critical thinking skills to solve problems based on daily life.

## Methodology

### The “Probability and Statistics in Daily Life” learning unit as a basis for teaching CT

“Probability and Statistics in Daily Life” is a preexisting learning unit developed by Lieberman and Tversky (2001), which was expanded and modified for the purposes of this research. I selected this unit as a basis upon which to build the teaching experiment reported in this paper because it was designed to teach mathematical content using problems and stories from daily life, and because its

rationale already alluded to “elements of critical thinking”, citing these among the “issues relevant to daily life” that it hoped to teach (Lieberman & Tversky, 2001, p. 3).

The original unit was based on Tversky and Kahneman’s well-known work on making decisions in conditions of uncertainty (Tversky & Kahneman, 1974; Kahneman, Slovic, & Tversky, 1982). It covers topics in statistics and probability in hierarchical order, connecting each to daily-life scenarios and decisions. The purpose of the original unit was to turn students into ‘intelligent’ consumers of information by introducing them to modes of thinking that went beyond the mechanics of mathematical calculation. The use of problems from daily life exposed the students to various additional fields such as medicine, economics, and law, illustrating the practical applications of probability and statistics to these fields and showing the students the ways that statistical considerations are inextricably woven into our lives. Furthermore, the unit’s composition required them to analyze problems, raise questions and think critically about the numerical data and the information placed before them. Faced with problems that did not necessarily have one correct, clear-cut answer, the students learned not to be satisfied with arriving at a numerical solution, but to assess the validity of data, and to assess the problems before them in a qualitative – and not just a calculative – manner. I composed a revised version (Aizikovitsh-Udi, 2012). The unit combines the hierarchy of topics in probability and statistics with a corresponding hierarchy of topics in critical thinking, so that, as the students progressed in the former, they would also progress in the latter.

### **Setting, population and data collection**

Results presented here are from a subgroup of one class taken out of a larger population of six classes (147 students in all, three experiment groups [70] and three control groups [77]). The larger population was used for deriving quantitative results regarding the experiment’s efficacy, which are not presented here. In this paper, I will present two groups: 18 students were taught by the researcher in high school 1, 20 students were also taught by the researcher in high school 2 in central Israel.

The experiment consisted of 15 sessions (90 minutes each) during the course of the academic year and served as the “probability and statistics” section of the students’ mathematics curriculum for that year. The group whose sessions are described here was the one taught by me, in my capacity as these students’ regular mathematics teacher. Data collection was conducted by way of triangulation between the following sources: (i) The students’ written products, including exams, in-class papers, and homework were collected. (ii) Sessions were recorded, transcribed and analyzed (paying special attention to their relation to CT skills). The teacher kept a log on every session. In general, data were processed by means of qualitative methods, which enabled me to follow the students’ patterns of thinking. (iii) Personal interviews: 27 students were randomly chosen (four from each of the seven experimental classes) and interviewed at the end of the first and second semesters, in the middle and at the end of the unit. Personal interviews were conducted in order to reveal changes in the students’ attitudes towards critical thinking throughout the academic year. The interviews were of two kinds: closed/structured interviews, based on questions chosen in advance, and open/semi-structured interviews, where only part of the questions chosen in advance was asked (possibly in modified form) according to the interviewees’ answers. The interview questions were: (a) What do you think about the importance of critical thinking ability? In which fields/activities is it important? (b) Can you give

an example of a situation (from school, everyday life, etc.) where critical thinking is necessary? Have you used it? Did it help you? (c) In your opinion, is it possible to develop/improve critical thinking ability? How? Do you have any suggestions for improving it? (d) In your opinion, is it possible to change dispositions for critical thinking? How? What influences the dispositions? Do you have any suggestions for improving them? (e) Did your studies in the other disciplines improve your ability for critical thinking? If yes, in what course and in what way? If not at all, why not? (f) How would you evaluate yourself in the area of critical thinking? The intended aims of the six questions were: (1) To ascertain the degree of students' awareness of the nature of critical thinking (mainly questions a, b, e, f, through the pertinence of the examples and the answers). (2) To identify students' ideas about possible fields of application for critical thinking (a, b), and in particular to identify suggested fields far from those proposed during the course (as a sign of interiorization and a premise for a possible transfer). (3) To get feedback about students' perception of which aspects/moments of the course had an impact on their CT skills and dispositions (c, d), as a way to assess students' awareness of the aims of the course.

## Results

### Analysing the Findings by two lessons

In what follows, I present two lessons, taken from three progressive points within the learning unit. For each, I present the daily-life topic upon which the lesson was based and show how first the mathematical content and then the thinking skills were integrated into it. In addition to exemplifying how the two topics were tied together, the succession of the lessons shows how both the mathematical content and the critical thinking skills built upon themselves hierarchically as the unit progressed, involving students in meaningful activities related to the aims of the learning unit (development of both CT and mathematical competencies). Each of the three selected samples also highlights a different element of the program. The first lesson, in which the students are sent outside of the classroom to gather data for themselves, highlights the centrality of the practical "daily life" element in the study unit. As this example shows, each daily life story or problem places the students in a position where they must draw on both the mathematics and the critical thinking skills to gather the information they need to make their decision. The second lesson is the most elaborated and detailed of the three examples, and it shows (through a long excerpt and the related analysis), how the melding working hypothesis was implemented (thus showing its feasibility). It also shows how by that point in the learning unit specific features of CT had already been interiorized by students, and how specific CT expressions entered students' language and were used by them in an appropriate way (see Discussion). The third example stresses the four-step format of each lesson, and emphasizes the function served by each: It shows how the daily life scenario triggered the students' intuitive response, which was then informed and modified by the mathematics before being rethought and adjusted a second time by further application of CT. This problem shows the unit's lessons at their final and most advanced stage, where the students see that CT can be used not only to support conclusions based in mathematics, but also to look beyond them.

### Example #1: The shoe size problem as an introduction to Simpson's Paradox<sup>1</sup>

This lesson (Aizikovitsh & Amit, 2008), taken from the point of transition between chapters one and two, introduced the mathematical concept of the “mediating factor” (see below). In terms of critical thinking, it engaged the students in: a) identification of relevant questions and variables; b) locating the source of information; c) evaluating/analyzing the validity of statements. The students were given the following dialog called “Shoes and Mathematics”:

Avi: “There is a connection between shoe size and level of mathematical knowledge.”

Beni: “Can’t be.”

Avi: “Go to the school in the next building and see for yourself.”

Beni: “You are right, the kids who wear bigger shoes really know math better!”

Why is this phenomenon true? What do you think about the conclusion?

The purpose of this lesson was to show the students that while causal connections *are* predicated on the presence of statistical connections, the presence of a statistical connection does *not* necessarily mean that a causal connection exists. Most of the students had a strong initial intuition that the causal connection was impossible, but they did not yet know how to explain and support it mathematically. After the preliminary discussion of the students’ intuitions, several of them were sent out to ‘gather evidence’ at the nearby elementary school, stopping random students and asking them: a) their shoe size, and b) what mathematical topics they were familiar with. This exercise introduced a critical element into the lesson, with the students validating the reliability of their source by gathering the (seemingly) corroborative data themselves. The ultimate purpose of this lesson is that the students recognize the logical fallacy in the connection suggested here between shoe size and mathematical knowledge by realizing that this connection is generated by a mediating element (the child’s age). The mathematical content of the lesson consisted in the translation of the information into a mathematical format (set theory) and the use of a two-dimensional matrix. I also performed new calculations that included the mediating factor C. I found that statistical connections exist between A (shoe size) and C (age), as well as between B (mathematical knowledge) and C (age). This, I argued, is the reason for the statistical connection between A and B. By means of this process and its illustration through the real-life example of shoe size, the students were introduced to Simpson’s Paradox and the concept of the mediating factor. The critical thinking portion of this lesson consisted primarily in the students learning to evaluate and question the validity of their information, even when they had obtained that information themselves, in recognizing the fallacious connection and in drawing an alternative, valid conclusion.

---

<sup>1</sup> Simpson’s Paradox refers to the situation where normalizing data from different ways of partitioning the same population will provide incompatible conclusions about the associations that hold in the total population. For example, a partition by gender might indicate that both males and females fared worse when provided with a new treatment, while a partition of the same population by age indicated that patients under fifty, and patients fifty and older both fared better given the new treatment. The relevant element for this paper is the role of the mediating variable (age or gender).

## Discussion & Conclusion

As the examples above show, the mathematical content of statistics and probability is well suited to being ‘infused’ with instruction in critical thinking skills. The hierarchical patterns in which both the content and the skills can be taught complement one another structurally, with more elements of critical thinking coming into play as the mathematics becomes progressively more complex. The two instructional goals (statistics and critical thinking) are also mutually beneficial in terms of content: The mathematics provides the students with a means to engage in critical thought and pursue independent challenges and confirmations to the information they are given. The “Probability in Daily Life” unit provides the mathematics with a practical ‘real-world’ context that can help the students comprehend the material more concretely as more than the abstract manipulation of numbers on a page. The various critical thinking skills could then be taught explicitly in the context of using mathematics to solve problems in the real-world situations. The addition of critical thinking provides an added reflective dimension to the mathematical treatment rendering both the approach and the results more meaningful to students.

Analyzing the findings, I have arrived at the following generalizations regarding the process of critical thinking skills construction and teaching: (1) It seems that critical thinking skills do not develop spontaneously and that even good students acquire them by means of explicit instruction. This finding is in direct opposition to Tennyson & Rasch (1988) claim that learning skills and learning strategies develop in the student spontaneously, without direct instruction. (2) To a large extent, the construction and teaching of critical thinking skills are determined by specific contents and tasks the teacher uses. In this research, the skills were chosen with respect to the contents and the increasing difficulty level of the learning unit. (3) It is possible to significantly influence and change the mathematical discourse of the classroom and the students’ language of critical thinking, by providing appropriate conditions and using appropriate instruction methods. This type of learning emphasizes the development of skills in the process of solving mathematical problems.

In much of the literature, critical thinking development is referred to as an important goal of the educational system. This research may contribute to the public discourse of the mathematical education community on this issue. It also raises the public awareness of the need to develop critical thinking in the framework of mathematical education, which may enable future examination and promotion of critical thinking development through mathematics teaching in a fuller and more informed way. To conclude, the main contribution of this research lies in revealing the connection between critical thinking and the teaching of mathematics. It should be possible to strengthen the status of the study of mathematics in imparting higher-order thinking skills, both in parallel with and beyond the formal education program. This paper has reported an investigation into the use of the infusion approach to teach critical thinking skills while also teaching conventional probability and statistics content. The students acquired critical thinking skills that they came to value.

*One of the latest reforms in Sweden in order to increase equity and quality in education is making national assessment compulsory in preschool-class (age 6). The claimed political volition is all students' best possible mathematical development. In this paper, we examine the preparatory work, the assignment to the National Agency of Education, and the assessment material itself, searching for what meaning is inscribed regarding the student, mathematics and assessment. The results imply that the politics of the assessment might exaggerate a search for flaws and control instead of promoting all students learning and in addition contributing to the schoolification of preschool-class.*

*Keywords: Early assessment, preschool-class, development in mathematics, national assessment.*

### National assessment in mathematics

National and standardised assessment has been vastly criticised and described as driven by a neo-liberal logic and securing market values (Dreher, 2012; Luke 2011; Lundahl, 2016). Equality and values of social justice, diversity and democracy are shown to be threatened by these kinds of tests (Hudson, 2011; Lundahl, 2016; Peters & Olivers, 2009; Rustique-Forrester, 2005). In Sweden there are currently three national tests in compulsory school that all students have to take: in grade 3 (age 9), grade 6 (age 12), and grade 9 (age 15). National assessment in mathematics, in the form of a support material, is also compulsory in grade 1, and voluntary in grade 2. The national assessment system has recently been evaluated (Regeringen, 2016). Since autumn 2019, this has led to a supplementation with compulsory national assessment also in preschool-class (age 6), which is a separate school form within the Swedish school system. The everyday assessment discourses in the classroom of the preschool-class are characterized by an activity-specific educational culture, which is meant to stand between the pre-school's and the school's norm systems (Vennberg, 2015). Important reasons claimed for developing the system are to direct teachers' attention, use of mathematical concepts, and efforts in certain directions, and through that striving towards equity and quality. These are in other words areas that are understood as important to govern. A core issue in assessment of preschool-class students' knowledge is also to early identify students in need of support. This is considered as a prerequisite for affording equal opportunities to learn, regardless of background factors. Another argument is to diminish the decrease of measured knowledge in grade 9, and the identified differences in the quality of support given to various students and in different schools (Regeringen, 2017a).

According to Boistrup (2017), a lack of equality can be found in the context of assessment at different levels within the school as a system. Assessment in mathematics can be said to hold a gatekeeping dispositive regarding the access to success. This dispositive may play out in the immediate situation of assessment if students belonging to disadvantaged groups face obstacles in displaying knowledge.

An example is when the teacher feels that securing multi-lingual students' equity could threaten the tests validity (Bagger, 2017). These findings from earlier research indicate that it is urgent to continue to investigate how the assessment and the teacher are governed. In this paper, assessment in mathematics education is understood as an element of governing (Foucault, 1994), where purpose and how it is carried out have impact on aspects related to quality and equity. Newton (2007) stresses that if several purposes of assessment – to evaluate education, to make grounds for decisions of recourses, and assessment of knowledge – are active simultaneously, conflicts of interests are built into the assessment, and a test will work poorly for all or mainly for some of the purposes. Further, how the teacher understands the student and the teaching content will have impact on the mathematical support (Scherer, Beswick, DeBlois, Healey & Opitz, 2016). Related to this, a study by Bagger (2017) indicates that the educational segregation in the teaching and learning of mathematics might occur earlier with earlier testing. Simultaneously, there are indications that if the preschool-class teachers get skilled in assessing mathematical knowledge, students at risk in preschool-class reach similar achievements as their peers in the national test in grade 3 (Vennberg & Norqvist, 2018). Our assumption is that assessment in the preschool-class constitutes a risk for but also an opportunity to levelling disadvantage.

The purpose of this study is to increase our knowledge of how policy documents govern the implementation of national assessment in preschool-class in mathematics. This is achieved through a systematic exploration of how some central aspects are discursively constructed: the student, mathematics, and assessment.

## Theory and methods

In this paper, discourse is taken as representations of power, truth and knowledge that govern individuals and society. Truth and knowledge are further understood as social constructs and as such they evoke power relations (Foucault, 1994). Popkewitz (2004) draws on Foucault's thinking and uses the concept of *fabrication* as a governing technology. Categories, for example central notions adopted in assessment practices, are conceptual constructs through which reality can be understood and is simultaneously fabricated. These fabrications communicate versions of truth, knowledge and power, and coincide with processes of exclusion and inclusion. Governing texts are regarded as *inscription devices* that attribute terms, possibilities, and characteristics (Popkewitz, 2012). In this case, the governing texts are the testing material, political preparatory work, and decisions, through which the student as a mathematician, the teaching content, and the assessment are understood as attributed with terms, possibilities and characteristics. In other words, the texts fabricate the student, the assessment and the subject, and also inscribe meaning into them. This might by extension affect how the student, subject and assessment are handled and understood in the practice and governing of national assessment in preschool-class. The governing may then concern what is considered as 'true', what counts as 'knowledge', how students' knowledge is valued, and how results should be used.

The texts selected to explore the fabrications of mathematics, the student and the assessment are preparatory work and political decisions regarding the assessment in preschool-class and the material for assessment (see Table 1). Initially, in the analytical process, statements concerning preschool-class were selected from the texts into a scheme in which each text was in its own column. After that,

all utterances depicting the student, the mathematics, or the assessment were coded in different colours. The next step was to ‘translate’ such utterances into explanatory paraphrases. The fabrications were thereafter narratively construed with regards to how terms, possibilities, characteristics, and demarcations were attributed. An example of the analysis is displayed in Table 2.

Text	Responsible author and short description
Skolverket (2016)	Comments to curriculum. Swedish National Agency of Education (SNAE). The purpose and content of mathematics in preschool-class.
Skolverket (2018)	National support for assessment in mathematics in preschool-class
Regeringen 2017a	Swedish Government (SG). The assignment to the SNAE to develop the national system for assessment including the material for assessment in preschool-class.
Regeringen (2017c)	SG. A bill guarantying support in reading, writing and counting.
Utdragningen om nationella prov (2016).	SG. A bill in which the need for assessment in preschool-class is put into the context of national assessment and the quality and equity of education.

**Table 1: Overview of the five documents analysed in this paper**

Selected text	Explanatory paraphrases	Construed fabrication
“To observe the students’ mathematical abilities in different areas of importance for development of mathematical thinking”	The purpose of the assessment is to identify student’s mathematical thinking	Lack of mathematical thinking is fabricated as the supposed obstacle for goal achievement in grade 3. Assessment will level inequalities in teaching and grant high quality and equal support earlier. Another threat against equity is the teacher who draws wrong conclusions regarding support or the displayed knowledge. So, they also need support.
“... early identify students who show indications of not achieving the goals in learning that are set for grade 3”	This is needed in order to identify students in need / at risk of not reaching goals three years later.	
“the assessment will help teachers to know what support to possibly put in”	Teachers need help to know how to support.	
“National material might increase the equity of the quality in the support given”	There is a lack of equity in the support now – another aim with assessment.	
“... solutions should be evaluated by someone else than the teaching teacher”	The teacher should not evaluate the solutions of her/his own students.	

**Table 2: Example of the analytic procedure and construction of the narrative**

## Findings

A narrative was constructed by depicting how mathematics, the assessment and the student were fabricated. All texts are in Swedish and quotes have been translated by the authors.

### The fabrication of mathematics

One aim of mathematics, as construed from the analysed texts, is to be a caretaker of curiosity and understanding: “The teaching shall take care of students curiosity and afford them the opportunity to develop their interest in mathematics and understanding for the possible use of mathematics in different situations” (Skolverket, 2016, p. 13). Also: “students shall be challenged and stimulated to use mathematical concepts and reasoning to communicate and solve problems in different ways through different representations and to explore and describe their surroundings” (p. 13). The areas of mathematics that preschool-class is supposed to pay attention to in order to reach the aim is: “Mathematical reasoning and different ways of solving problems” (p. 20) together with “Mathematical concepts and representations” (p. 21). Mathematical reasoning is defined as a “logical mathematical argument that is used for motivating an answer or a choice” (p. 20), and mathematical problems are defined as “situations or tasks in which the students do not know beforehand how to

solve the problem” (p. 20). The mathematical contents that the students are supposed to be offered to meet are:

the characteristics of natural numbers and how they can be used to designate cardinality and ordinality.... mathematical concepts and representations in order to explore and describe space, location, shape, direction, pattern, time and change. (Skolverket, 2016, p. 21)

Mathematics is, through the above-mentioned statements, fabricated in the curriculum for preschool-class as a nurturing and caretaking assignment that will grant the student an opportunity to further develop an already existing curiosity, interest and understanding. The mathematical content is fabricated as a kind of founding building blocks needed in order to explore and investigate various problems and arguments. Problems and reasoning that could impose interest and curiosity are additionally fabricated as deriving from visuospatial elements of the student’s surroundings. We interpret the intentions of mathematics education, as described in the curricula, as a way of supporting the students in experiencing themselves in the world, appreciating diversity in ideas and recognising their own competence to deal with problems.

In the title of the material for assessment itself, mathematics is labelled as mathematical thinking: “Find the mathematics. Evaluation material in mathematical thinking in preschool-class” (Skolverket, 2018, p. 1). In other words, it is fabricated as something that resides within the student. The material encourages the teacher to promote different arguments, reasoning, examples, and not to stop or be content with just one solution from students. This approach towards exploring is in line with the curriculum’s intentions. The areas through which the mathematical thinking is supposed to be explored and evaluated are patterns, maps, counting, sorting, and volume. The focus on experiencing the world and relations in it, in both the curriculum and the material, fabricates mathematics as something concrete and visible that constitutes reality. We wish to connect this to Straehler-Pohls (2015) writings of distributive rules in relation to school mathematics;

The foundation of this distribution is a stratification of mundane and esoteric meanings. In this stratification, esoteric meanings inevitably take the dominant role, as it is these meanings that transcend the spatial and temporal materiality that bear the potentials to think yet unthinkable solutions that draw on (contextually) external frames of reference” (p. 3).

Mathematics as concrete and constituting is further interpreted as fabricating school mathematics in preschool-class as mundane, at the same time as the exchanged meaning making is supposed to take place in an esoteric form through an exchange of different understandings and reasoning. The promoted variation in reasoning and solutions connects to a fallibilist (Ernest, 2014) view on mathematics in which knowledge is considered fallible and open for revision. In the assessment material, there is an attached observation scheme in order to register the student’s knowledge. A text on this is: “date when the observation point is reached/finished” (Skolverket, 2018, p.1 in compilation form). This assumes knowledge to be possible to observe, reach and check at a certain date, fabricating mathematical knowledge as situated in an absolutist perspective (Ernest, 2014) in which knowledge is secure, fixed and objective. This is opposed to the fallibilist view, represented in the previously described encouragement in the material and curriculum; to explore and negotiate

solutions and arguments. It also fabricates the mathematical thinking, or knowledge, as something that could and should be reached – *as if* there were goals to achieve in preschool-class.

### **The fabrication of assessment**

The title of the assessment material is: “Find the mathematics: Evaluation of mathematical thinking” (Skolverket, 2018). Assessment is thereby fabricated as needed in order to capture the inner world of the student, the thinking, or the lack thereof. The thinking is further fabricated as promoting or threatening a development of knowledge towards the goals in grade 3: “... is carried out during autumn in preschool-class so that the teacher can early identify students who show indications of not achieving the goals in learning that are set for grade 3” (p. 3). This message is also repeated in the preparatory work and the assignment to the Swedish National Agency of Education to develop this material. In addition, assessment is in these preparatory texts fabricated as something that will level inequalities in teaching and grant high quality and equal support earlier: “Nationally produced material might also increase the equity of the quality in the support given and contribute to a common terminology regarding assessment, progression and knowledge requirements which will lead to higher quality of judgements” (Regeringen, 2017a, p. 5). Teachers are fabricated as being responsible for detecting where in the development the student is and to adapt teaching so that the student can achieve the goals in third grade. This is seen in several parts of the texts and in the instructions to the material. For example: “to give teachers a clearer basis for assessment of the student’s knowledge development and more information on what support to introduce” (p. 2). Also, the material will evaluate the teaching and help teachers to correct it through “affording preschool-class teachers and teachers support in seeing how opportunities and obstacles in the teaching impacts on students learning.” (pp. 1–2). The proposition further fabricates assessment as insecure and invalid due to the teacher and relations involved: “solutions should be evaluated by someone else than the students’ teacher, and such solutions should be de-identified” (p. 1). Another statement fabricating the teachers as the ones in need of support is in the assignment to the national agency of education: “the material will be completed with a supportive material for analysing evaluations” (p. 2). The assessment is then fabricated as a tool to control and support teachers in the assessment process.

### **The fabrication of the student**

In the curriculum, the student is fabricated as already mathematically able and interested: “Teaching shall take students curiosity into consideration and give them the opportunity to develop their interest in mathematics and their understanding of how mathematics might be used in different situations” (Skolverket, 2016, p. 13). This harmonises with statements in the instructions to the material in which the use is presented as an opportunity in itself to learn mathematics: “By allowing students to meet activities that differ in character, they can develop trust in the ability to solve problems in different situations and contexts” (Skolverket, 2018, Instruction to material, p. 4). The student is thereby fabricated as a learner, rather than a test-taker. This stands in contrast to other statements in which the students are depicted as needed to display their knowledge. Such statements occur in the preparatory work and the material itself. The curiosity and interest that was fabricated as mathematical entities within the student and as something that the school should build on in the curriculum is instead fabricated in the material as a kind of mathematical knowledge that the student

must display. “When the student shows curiosity and interest for the mathematical content, it reflects how the student participates in the activity” (p. 4). The participation is further fabricated as the notion that will inform the teacher about “where the student is in her/his development” (p. 5). In the preparatory work, the assignment, and the material, there is an overweight towards the student being fabricated as lacking or possibly missing knowledge, that those errors may grow and therefore need to be identified and corrected through adaptations of education.

## Conclusions and discussion

A higher degree of goal achievement and increase of test-results have been central arguments in the evaluation of and revision of the national system for quality measuring (Regeringen, 2017b). This stands in contrast with the preschool-class’s pedagogical assignment of being a bridge between preschool and school. National and compulsory assessment in preschool-class is a new phenomenon and it is crucial that it is implemented in a manner that is in line with this educational spirit of preschool-class. Otherwise, the assessment might not present an opportunity to nurture interest, curiosity and the identity of being a mathematical learner and explorer, but instead contribute to an approach in which it is the performed interest or competencies that counts. The preschool-class could risk being colonised by the prevalent neoliberal logics of governing that exists in compulsory school including *schoolification* of the assessment practice in mathematics.

A focus on mathematics as the observed and displayed activity, and the assessment of knowledge as making achievement visible, positions the 6-year-old preschool-class student as a test-taker and the teacher as the controller and corrector of knowledge. The mathematical thinking and development were fabricated in the data as having a certain order or being a destination. To identify where the student is positioned on this map or road, is claimed as a key for giving adequate support early. A question to raise is how the teacher is supposed to position the students’ place in development through observing their displayed participation, as suggested (and we are reluctant to the idea of assigning students places in developmental ‘paths’, but that is not in focus in this text). It may be many factors that affect how and if a student participates, several of these have to do with the organisation of education and teaching. These are mentioned in the material with regard to the importance that students are allowed to express different ideas, which can also happen with other modes than spoken language. The stress laid on the freedom to communicate and try ideas indicates that it should be an explorative and playful situation. Also, knowledge can be displayed outside these situations or with other alternative and adaptive settings. These fabrications stand against the one of control and goal achievement. An adapted and creative mathematical teaching is supposed to be the possible outcome from the analysis of the material. We question how this can happen, in a practice deriving from an assessment that is only assessing a few mathematical items. This is significant, not least since the risk of ‘teaching to the test’ is obvious. Another aspect is how the mathematical processes, selected and tested in the material, are promoted as *the* mathematics, which is limiting in itself. There is a risk that the material may contribute to the narrowing of implemented curricula, teaching to the test, and seeing students as their levels of achievement, as reported in previous research (Wrigley, 2010). Thereby, the material may unintentionally limit possibilities for development and knowledge in mathematics, which is opposed to the purpose of increasing equity and quality.

The described use of the assessment material is easy to interpret as being about a search for problems, rather than promoting education for all. The strive towards high quality and quality in equity is then becoming an issue of everyone doing the same thing, having the same focus and the same demarcation in regard to the support given and the mathematics taught. A final question is: Is this assessment material a material for teaching or a material for controlling, and if so, what is being controlled and thereby restricted, locked in, or included? What is excluded when it comes to kinds of students, kinds of mathematical knowledge and kinds of teachers' ways of teaching? Our hope is that the discursive fabrications, presented in this paper, of assessment, mathematics and who the student is, may contribute to revealing some of the underpinnings in the so-hard-to-grasp patterns or structures of disadvantage in mathematics education.

*This paper considers what the praxis of ‘Funds of Knowledge/Identity’ (FoK/I) might offer to researchers and practitioners of mathematics education. Building on a critique of FOK/FOI as reflecting cultural capital (in Bourdieu’s sense) we posit the notion of ‘use value’ in the knowledge and practices of oppressed communities: in knowing how to live poor, how to resist capital, and how to solidarise in social movements related to class, nationality, race, gender, sexuality etc. We focus on ‘dark’ FOK - defined as difficult or challenging experiences for learners and/or communities; we reconceptualise these as related to the objective relations of oppression under capitalism whereby ‘dark funds’ are the surfacing of class contradictions in our learners’ experiences. The implications for critical mathematics education are led by these considerations: in the problems we choose to tackle, the partners we choose to work with, and the research methodologies we adopt.*

*Keywords: Funds of knowledge, funds of identity, social class, mathematics.*

## **Introduction**

The Funds of Knowledge (FoK) (and more recently Funds of Identity – FoI) perspective has increasingly been utilized by those interested in addressing issues of inequality and oppression in education (including mathematics education, González, Andrade, Civil, & Moll, 2001). Arguably, mathematics is a significant area of the curriculum for such work given the commonly accepted ‘gatekeeper’ role it plays in sorting and selecting who has access to high status careers/subjects and its function in excluding those from disadvantaged backgrounds (Jorgensen, Gates, & Roper, 2014). In this paper, we present a narrative review of the literature on FoK/FoI in order to demonstrate how key critiques present important implications for how we conceptualise and how we ‘do’ critical mathematics education.

## **Funds of Knowledge/Funds of Identity in/for Mathematics Education**

The ‘Funds of Knowledge’ (FoK) approach, originally developed by Moll and colleagues at the University of Arizona working with Latino immigrant communities and schools, has sought to emphasize the rich resources children have access to and experience in the home/community environment. In order to challenge the normative assumption that children from such communities are in some way ‘deficient’, it presents home activities (and the associated knowledge) as a rich resource for developing and teaching a school curriculum orientated towards social justice which are embedded in complex/rich social networks. The premise is that building a curriculum on these ‘funds’ will establish more meaningful connections between the school curriculum and learners lives beyond school. In one example, Moll, Amanti, Neff, and Gonzalez (1992) documented the development of a

learning module around the FoK evident in the home of one child, Carlos, who engaged in buying and selling Mexican sweets to friends and relatives after visits to Mexico. This is presented as a hybrid curriculum since it initially involved bringing the home experience into the classroom (e.g., parents came into the classroom to make Mexican sweets with the children) but then incorporated formal curriculum knowledge (e.g., the ingredients of Mexican and American sweets and comparison of their nutritional value). According to Moll et al. (1992) the term ‘funds’ originated from the ‘household funds’ paradigm (in anthropology) and refers to the funds that households must juggle to make ends meet – rent, social funds, ceremonial funds – each fund entailing a wider set of activities requiring a specific body of knowledge.

The essential cultural practices and bodies of knowledge and information that households use to survive, to get ahead or to thrive [...] acquired primarily, but not exclusively, through work and participation in diverse labour markets. (p. 21)

More significantly, Moll et al. (1992) were keen to point out that a FoK approach is not merely a culturally sensitive curriculum – or rather a ‘static grab bag’ of food, dances and celebrations which prove tokenistic (here they align with studies on ethnomathematics/culturally responsive pedagogies in mathematics education which also makes a similar critique). But rather this type of knowledge is strategic to households’ or communities’ functioning, development and well-being, and particularly may relate to the social, economic and productive activities of people in a local area.

More recently, Esteban-Guitart and Moll (2014) extended their approach to include ‘Funds of Identity’ (FoI) which refers to moments where a FoK is used to make some claim to be a certain kind of person:

funds of knowledge become funds of identity when people actively internalize family and community resources to make meaning and to describe themselves. (p. 33)

In this sense, they argue that education/teaching-learning should be about identity development as well as knowledge creation since the two are interwoven. Drawing on Vygotsky’s notion of *perezhivanie* (defined as an emotional experience having developmental potential, Blunden, 2016) they emphasise the subjective significance of the situation on the persons as they consume and use FoK. More so Esteban-Guitart and Moll (2014) define ‘the term *funds of identity* ... [as] a set of resources or *box of tools and signs*’ (p. 37). The authors highlight five types of funds of identity: ‘(1) Geographical Funds of Identity..., (2) Practical Funds of Identity..., (3) Cultural Funds of Identity..., (4) Social Funds of Identity..., and (5) Institutional Funds of Identity’ (p. 38).

FoK/FoI approaches have been utilised within mathematics education (Moll et al., 2009; Gonzalez et al., 2001) and clearly there is commonality with the ethnomathematics tradition (d’Ambrosio, 1985) and Critical Mathematics Education (CME) (Gutstein, 2006; Skovsmose & Nielsen, 1996); although CME is usually viewed as perhaps more explicitly political, involving critical interpretations of the world and political engagement (see, e.g., Skovsmose, 2016). The FoK approach is largely deemed critical because it rejects a deficit point of view on the learners (typically of immigrant or otherwise disadvantaged or marginal communities) vis a vis their ‘capital’. Moll and colleagues (2009) argue, and their research findings establish this, that many children bring funds or resources that could be useful to teaching/learning, but that go unrecognized by the teachers/schools because of their

ignorance of the culture involved. In this respect, this perspective also sits well with the Vygotskian idea of the everyday/spontaneous practices of the learner as providing potential for ‘making sense’ of the formal, academic concepts of the school curriculum and its teachers.

### **Critiquing the ‘Funds’**

Williams (2016) has offered a critique of this work, drawing on Bourdieu, which illustrates how FoK/FoI has been used to refer to the surfacing of capital in the home/community as a means to reposition the learner with ‘access’ to the school curriculum. For instance, Moll et al. (2009) describe how the teachers-researchers involved in their projects discover one Mexican family’s educational values and high aspirations for their children which were previously been unseen/unrecognised by the school. Here the identification of FoK may be to enable the redistribution of such ‘capital’ by making visible and legitimate home resources and by providing the machinery to ‘scaffold’ the movement of such capital from the home into the educational field as a means to access ‘success’ and capital growth. According to Williams (2016), in such cases, identifying FoK does not necessarily challenge the process of capital exchange, but instead serves to strengthen its orthodoxy as ‘natural’ and open to all. As Zipin (2009) notes, the very act of identifying ‘everyday’ or ‘lifeworld’ knowledge to facilitate access to more powerful or ‘elite’ cultural artefacts entails the loss of its use value (productivity) and transforms such knowledge into objects with exchange value to be mobilized for capital growth in the educational market (he defines this as an ‘asset’ perspective).

When schools operate as high-stakes competitive markets, the use values of diverse people’s cultural assets are sadly diminished in relation to ‘gold standards’ of restricted exchange value. (p. 319)

However, poor communities also have resources which may not be valued as ‘capital’ and may even function to resist capital exchange within the educational field – for example, parents who question how they are positioned by schools in terms of capital ‘deficit’ and express confusion as to why schools do not teach the ‘life skills’ they practice ‘everyday’ as a function of ‘being poor’ (Howker, 2018). Both Bourdieu and Freire – were they alive today – might argue for the need to disrupt the ‘orthodoxy’ which occurs when FoK/FoI approaches are used to merely surface capital in the home/community (thereby strengthening the process of capital exchange). For Bourdieu and Wacquant (1992), it is the reflexive sociologist who, having made visible the processes of capital production/reproduction, might support practitioners/communities in identifying with a heterodoxa in a given field (i.e., an alternative frame which challenges orthodoxy and so threatens the ‘doxa’ in place). Similarly, Freire’s (1970) *Pedagogy of the Oppressed* suggests that emphasis should *not* be placed on resources ‘latent’ in the home/community practices which are useful to a formal curriculum of some sort but rather on how such resources can be brought to consciousness in order to ‘name’ (and challenge the limits of) the systems/relations/institutions which produce/reproduce oppression/inequality. Freire also outlines a process of conscientization where collective agency/solidarity and social movements are mobilized to fight struggles of injustice pertaining to class, race, etc. Through the pedagogy of the oppressed students can “perceive the reality of oppression, not as a closed world from which there is no exit, but as a limiting situation which they can transform” (p. 85). Here the agents are students/community members/teachers/activists rather

than the social scientist (as per Bourdieu), although special status is given to the ‘educator’ whose role is to draw out the learners’ view of reality and enable him/her to question it.

All of this suggests the need to situate FoK/FoI in relation to the objective relations of oppression, which under capitalism may be understood as relations of class position (dominated/dominating, working/leisured, disowned/owning class positions in Bourdieu). In identifying the types of knowledge embedded in homes/communities and the subjective experiences they engender (FoI), it is not sufficient to relate to ‘domains’ of activity (e.g., home/community etc.) in which they arise or even the social function that such activities serve (e.g., practical/institutional etc.). But rather we need to recognize how FoK/FoI function in relation to objective structures which (re)produce ‘capital’ (either through alignment or resistance) if we wish such an approach to challenge oppression/alienation of those from disadvantaged communities.

### **Dark/Existential FoK/FoI**

In relation to the above critique, Zipin (2009) notes the difficulty of developing a curriculum based on the ‘use-value’ of FoK and anticipates the challenges and limitations presented by institutions whose function is to mechanize capital exchange (Bourdieu, 1986). In this sense, he critiques the tendency of researchers/teachers to gravitate to what he terms ‘light’ FoK or rather positive experiences and to omit what is seen as more difficult or challenging sides of living in disadvantaged or poor communities. As such, dark FoK are conceptualised as knowledge/resources/experiences which may be painful, challenging or difficult (e.g., bullying, poverty, incarceration, mental ill-health, exploitation, or other problems with social relations) and which Zipin (2009) argues are significant if we wish to fully recognize how poverty and class position permeate the ‘habitus’ of children. More recently, Poole and Huang (2018) have made a similar argument in relation to existing accounts of FoI (Esteban-Guitart & Moll, 2014) critiquing the heavy focus on the learner’s positive experiences, rather than capturing the whole range of human subjective experience. They suggest that difficult experiences or rather ‘existential FoI’ (identified through an ‘experience as struggle’ lens) are significant since they indicate a *perezhivanie*, that is emotional experiences which are/can be developmental in that they provoke the need to work through or reflect and subsequently overcome. Thus whereas Zipin (2009) sees dark funds/difficult experiences as offering a potential FoK approach which can counter the logic of capital exchange in teaching and learning (since ‘dark funds’ are not merely a matter of identifying ‘assets’ for capital exchange), Poole and Huang (2018) suggest such potential be located at the subjective level – with difficult or challenging experiences viewed as developmental in that they may bring about ‘human growth’:

Existential funds of identity are defined as positive and negative experiences that students develop and appropriate in order to define themselves and to help them grow as human beings. Existential funds of identity are presented as an additional category of funds of identity that are designed to complement the typology consisting of geographical, social, cultural, institutional, and practical funds of identity as developed by Esteban-Guitart. (Poole & Huang, 2018, p. 126)

In the above quote we can see how Poole and Huang (2018) equate existential FoI to other categories proposed by Esteban-Guitart and Moll (2014) as if they are merely an alternative form of resource/experience which individuals encounter. However, our own work on *perezhivanie* has begun

to look at how emotional experiences (difficult/challenging or otherwise), although experienced subjectively, may also be related to objective structural conditions whereby contradictions arise. For instance, in Black, Choudry, Pickard-Smith, Ryan, and Williams (2018) we present the case of 6-year-old Nico who experiences his classroom mathematics as ‘boring’ and in contradiction with his home/community activities where he is able to ‘see’ some embedded mathematics ‘in practice’. We have highlighted in this paper how this contradiction is experienced subjectively but also how it arises objectively in social structures, that is as a manifestation of the family habitus regarding school mathematics as ‘not for them’ which contradicts the embedded mathematics used by Nico, his family and his community in their everyday practice. Thus, we propose that dark/existential FoK need to be reconceptualised as manifestations of (and so refracted through subjective experiences of) objective relations of oppression under capitalism whereby ‘dark funds’ arise from the surfacing of class contradictions in learners’ experiences. In general, the habitus of the oppressed is not well aligned with the cultural capital needed to resource the acquisition of power in the various fields and in the field of power generally. However, just as we must imagine a world beyond such arbitrary power structures, we must imagine the potential of such experiences to resource developments of new understandings and consciousness of ways to live differently. In this simple formula we may reposition Vygotsky’s conception of *perezhivanie* in a critical class context, as the potential of experiences for development of newer and bolder class consciousness.

### **Implications for Critical Mathematics Education**

Our critique of Poole and Huang’s (2018) conceptualisation therefore suggests that ‘dark’ experiences, if they are understood in the way we outline above, can give insight into how we might relate productively to them, and how they might be made to become developmental in a critical sense. This may entail finding ‘uses’ of mathematics in the home/community and in class struggles which can be mobilised to fight real issues of poverty or oppression in the way Freire (1970) envisaged. See, for example, Gutstein (2016) for a course designed with this explicit orientation. Examples where such an orientation integrates with actual struggles and campaigns are far rarer, however. Williams, Bertholt, Nardi, Jornet-Gil, and Vadeboncouer (2018) have more recently made the distinction between ‘critical’ and ‘domesticated’ forms of CH-AT in educational praxis: Our remarks in the previous paragraph suggest a critical perspective on *perezhivanie* to balance the more domesticated, personalized one attached to psychotherapy (i.e., that ‘development’ is a purely personal, therapeutic one rather than an emergence of class consciousness). The critical perspective may involve working with the experiential ‘resources’ that capital is not interested in, but that allows or encourages a different ‘knowledge/know-how’. Zipin, Sellar, and Hattam (2012) refer to such resources as ‘knowledge that has use’ as opposed to knowledge that ‘has market-exchange value’ thus:

knowledge that has uses for social life in those settings – not abstracted from living social use by a logic of accumulation of knowledge that, due to its scarcity, has ‘market-exchange value’ which can be parlayed by either individual ‘entrepreneurs of the self’ or networked collectives of ‘social capitalists’. (p. 181)

We should add to this ‘knowledge that has use’ in the struggles of the oppressed. Most obviously such ‘resources’ relate to how to ‘live poor’, but we also argue, following Freire, the need to recognize

and legitimate practices and know how involved in sharing/mobilising solidarity with others who are oppressed and also how to engage in collective action, for example through social movements and community, union or party activity. One might also see how such resources can challenge the ‘limits’ Freire refers to in the education-industry, for example in asserting the need to overcome the disciplinary boundaries (in curriculum and pedagogy), spatial and temporal structures in educational institutions, and above all assessment and qualification structures (Williams et al., 2016).

*This paper discusses the solidarity assimilation methodology (SAM) under the critical scrutiny of the community, as a strategy of intervention in an inherently exclusionary school system. This intervention has been operating for almost 40 years in direct contact with the classroom and in the context of institutional obstacles faced by the authors. The core principles of SAM is to distinguish promotion from evaluation and to conflate rewarding effort with content progress as promotional criterion leading to credit. SAM adopts the motto “we teach when we listen, we learn when we talk”. We argue that this common belief in progressive pedagogies acquires a deeper meaning under a Lacanian perspective. Rewarding effort is less easy to digest because it forces us to politicise our work. The problem of universal failure will not be solved by SAM, but SAM provides an understanding-in-action of the role of failure in the resilience of school practices.*

*Keywords: Solidarity Assimilation, Hegel, Marx, Lacan*

## Introduction

Solidarity assimilation methodology (SAM) is an intervention into capitalist schooling that started in Brazil through the work of Roberto Baldino and Tânia Cabral. Contrary to other approaches in mathematics education, SAM is not a bird's-eye view on the teaching and learning of mathematics, developed by a researcher who is not teaching mathematics. Instead, it born out of the necessity to deal with the daily difficulties that Baldino experienced when trying to teach mathematics to his university students at the Federal University of Rio de Janeiro in the early seventies. Since then, other people, including Alexandre Pais, have joined in the development that is now well documented in the research literature (e.g. Baldino, 1997, 1998a, 1998b; Baldino & Cabral, 1989, 1998, 1999, 2006, 2008, 2010, 2013; Baldino & Carrera, 1999; Cabral, 1993, 1998, 2015; Gluz, Cabral, Baggio, Livi, & Mallmann, 2008; Pais, 2011; Persad, 2014; Silva, 1997). In the present article, we briefly describe the main aspects of SAM and point to a research project to be developed in the years to come. The following personal testimony of Alexandre Pais completes our introduction.

The reality of the classroom forces teachers to believe that we are all struggling for “mathematics for all”, at the same time making it difficult to sustain the illusion that a complete pedagogy can be achieved. This led Alexandre – at the time a mathematics teacher in a Portuguese school – to find in the work of Baldino and Tânia elements to understand his everyday reality. For the first time Alexandre saw a lucid account of the sociopolitical problems he was experiencing as a teacher. While mathematics education research was roughly divided between a ‘didactical’ approach, with no social or political concerns whatsoever, and a ‘postmodern’ approach, with its emphasis on discourse and

power relations, Baldino and Cabral were using old Marxist categories to analyze their work as mathematics teachers at the university (e.g., Baldino, 1998a, 1998b; Baldino & Cabral, 2006).

Their research spoke to Alexandre because he felt in their work an attempt to show the “shit” (Pais, 2015) involved in schooling, instead of trying to disguise it through the report of successful experiences which teachers find difficult to associate with their practice. Indeed, the reader will have to search hard to find in Baldino and Tânia’s research one example of a successful experience. This is because they are not talking from above to an arranged classroom (where someone else is doing the work of teaching). They are researching their own teaching and, as such, cannot afford to play the narcissistic game that so often populates mathematics education research (see, for instance, Pais, 2017).

One can say that Baldino and Tânia anticipated what is now known as the “social turn” in mathematics education. Studies within this vein emphasize the importance of considering how what is happening in a classroom depends on the entire social, cultural and political frame. These studies highlight the importance of “social interactions” and the role of “culture” when learning mathematics; they also raise broader issues of equity and social justice in accessing mathematics education (Gutiérrez, 2013; Sriramann & English, 2010). A problem with these studies however, is their disavowal of the *economy* when addressing the question of failure in school mathematics (Pais, 2014).

Despite the diversity of studies animating the social turn, what binds them is the rejection of a central organizing principle, which takes into account how schools manifest the totality that capitalism is today. In a postmodern research-world, it is not easy for researchers to posit capital as the “concrete universal” of our times (Baldino & Cabral, 2018). To do so, will imply a questioning of not only the structures and actors that exercise damaging influence on school mathematics (governmental policies, discourses, etc.) but also a questioning of our own role worsening what we intend to improve (Pais, 2015). In what follows we briefly present what can be considered the main principles of SAM.

### **SAM’s birth scenario**

Here, we briefly describe the political context where SAM was born so that the reader can understand why we say that this methodology is an intervention in an elitist undergraduate teaching context and how it is an understanding-in-action of a system which is inherently thwarted.

In 1972, under the military dictatorship, the Brazilian economy was growing steeply, an illusion that did not last long. In that scenario, students’ meetings were strictly forbidden, many professors had been expelled from universities, some students were killed in demonstrations, others disappeared, the press was under control and observers disguised as students watched every classroom. In 1969, a university reform had opened access to underprivileged students to higher education. A radical elite expected that failure, especially in calculus courses, would push these newcomers out. Most teachers developed personal strategies to accommodate the situation. People engaged in SAM<sup>1</sup> called the prevailing exclusionary pedagogy, *current traditional teaching* (CTT).

---

<sup>1</sup> Mainly, Charles Guimarães and his group.

According to the military, teachers were supposed to speak for the entirety of the class, and the students should listen quietly. Teachers of CTT dedicated their attention to stimulating stronger students while passing the weaker ones who had not learned enough, based on criteria tinted with social and ethnical prejudice; for instance, manners and speech associated with those of the upper class counted as hidden subsidiary criteria. As a consequence, CTT stimulated rote learning and enabled students' to gain credit without learning.

Implementing an alternative pedagogy became an urgent political issue to those who opposed the regime. Baldino tried to approach the students who were repeatedly failing in the two mid-terms and one final exam each semester. However, the prompt answers of the academically successful elite presented an obstacle when he tried to address the difficulties of these students, e.g. by offering simpler questions during class. Extra class activities were monopolized by questions from the mathematically stronger students. His attempts to reduce the number of students per class had little support from the administration and faced considerable opposition from the leading students.

### **SAM's pedagogy**

There is much literature on pedagogy and didactics but the meaning of these terms is not always clear. In order to develop SAM as a pedagogy of intervention, we must say that, by pedagogy we refer to the institutional conditions designed to engage the students with the learning task, mostly through what Vinner (1997) called the *credit system*. We acted on these conditions introducing rules to get credit in group work. These so-called norms of SAM were developed over a decade. Each semester began with a description of the rules adopted in the previous one, followed by a report of defective results. Then, a modification of the rules was suggested and a question was made: does anyone have a better idea? We finally arrived at a stable set of norms to include assessment of classroom work as a promotional criterion leading to credit, thereby distinguishing SAM from other pedagogies based on assessment. These norms provided us with the necessary empowerment to face the disruptive elite. They allowed contact with weaker students during classes, without harm to stronger students, and with all students separated into ability groups. In this way, SAM became an efficient instrument to rebuff disruption or the monopolization of classes by the radical elite. SAM intervened in CTT by, on the one hand, culturally rewarding underprivileged students according to what they could give, namely work and, on the other hand, constraining the white-male elite to submit to the classroom organization.

*Basically SAM conflates effort-based with content-based promotional criteria.* The class is organized into groups of four; the students are expected to engage in the task of solving *and understanding* the solution of assigned exercises. SAM norms, under the form of a work contract, are presented in the first class; after a two or three weak clearance trial they are put to a vote, against CTT. Generally the supporters of SAM prevail. Before asking for help, the group must decide what they are going to ask. In case of divergence in the group, each student must report the point of view of the other. The group must work together on each exercise and never pass to the next without showing understanding of the solution of the former. If everything goes well, the group receives credit points proportional to the duration of the work. *Only effort, not content progress counts at this moment.* These points count as a bonus to be added to the grades obtained in the classical CTT summative assessment represented

by individual exams. Individual disruption of the norms, count negatively *to the whole group*; group disruption of general classwork, such as failure to be silent at collective moments, count negatively *to the whole class*. Cases of disruption are reported in the fifteen-minute final plenary session occurring after each one-hundred minute class.

Difficulties with implementing this strategy in the classroom can be addressed, provided that we recognize the differential progress of different ability groups and adjust our help accordingly, formulating different questions to different groups. The organization of the SAM classroom is further discussed in Baldino (1998a), and Baldino and Cabral (1999, 2010). The content progress made in each class, is what we call *understanding* and how operational and preferential this understanding will be in the next class, is what we call *learning*. SAM was developed under the supposition that understanding implies learning. However, along the way we have found out that this is not necessarily so (Baldino & Cabral, 2005). We tell the students that we can assure understanding, but learning is a result of their attitude with respect to the discipline, the university and, in general, to life.

It soon became clear that opposition to SAM was not only an “educational” questioning, but a truly *political* one. We are not advancing *effort-based promotion* as the solution to the segregation problem, but these questions force us to examine the promotional criteria used in CTT—how do we, as teachers, arrive at a “grade” that is supposed to condense everything that the student did during a certain period of time? Once we take up such political questions, new ones emerge. What criteria do we have to impart credit to some students and deny it to others? What are the consequences of our denial to the life of a particular student? Should we base our promotional criterion exclusively on assessment of content progress? Are we allowed to take our own classrooms as objects of research, introducing unexpected changes? SAM has been considering such question since the 1980s (e.g., Baldino & Cabral, 1989).

### **SAM’s psychoanalytical slant**

From first pioneering report (Baldino, 1997) to the recent presentation in MES 10 (Cabral & Baldino, 2019a), our work (see below) reports the results of our classroom practice based on SAM, and is mainly concerned with economy and psychoanalysis. Here, we only have space for a brief discussion.

“You teach when you listen, and you learn when you talk.” This motto calls up the vast literature that posits the student as constructor of her own learning and holds that the teacher’s role is to formulate questions, not to give answers. Relying on Lacanian psychoanalysis, SAM reformulates some meanings of progressive pedagogy. Within SAM, ‘making questions’ in a situation of individual tutoring, means driving the student into *contradiction*. ‘Listening’ means to let oneself be hypnotized by what the student says, in an “upside-down hypnosis” (Lacan, 1973, p. 245). ‘Not giving answers’ means to follow up the student’s saying with new questions, to keep the focus of the initial contradiction until she perceives what irreducible signifier she was attached to. Finally, ‘talking’ refers to the student’s expression of her new understanding.

SAM adapts the directives of the clinic to the classroom through the concept of *pedagogical transference* (Cabral, 1998), where the teacher controls the level of anxiety by opening and closing the lack of understanding that the student perceives with respect to mathematics. The teacher assumes a special position, called the *Other’s position*, in such a way as to suggest that she may also have a

mathematical lack. When the teacher listens, the student cannot figure out whether he is just trying to understand what she says or whether he is trying to take time to think. SAM seeks to assure the student that she will not find in this Other, the fulfillment of the lack that would allow her to pass (gain credit) using rote learning. The teacher endeavors to keep the student's fault open, leading her to ask herself: *Did I understand? What do I really want?*

In fact, anxiety emerges when the student presupposes that this lack may lack, that is, when she evaluates that she has actually understood; in this case she becomes vulnerable: what if in her next answer the lack is filled with a negative teacher's verdict? The teachers' listening is selective, but sufficient to detect signs of anxiety in the student's gestures and speech. Negative individual verdicts should be avoided and replaced by further questions, otherwise they may cause unbearable anguish. The organization of the classroom into ability groups is fundamental in SAM: a negative verdict which addresses a common mistake made by the whole group, produces coalition and positive excitement instead of anxiety.

If, on the contrary, the teacher hides his own lack behind a position of *subject supposed to know* and provides ready-made explanations, he obliterates both lacks, his and the student's. From this position, he produces the illusion that the student understood and he denies the student the opportunity to face her ghosts and develop her own *savoir* about her learning process. She has no chance to come to "love maths anxiety" (Baldino & Cabral, 2008).

SAM is a way of sustaining the student's lack and accepting her initial position of not wanting to know about a *savoir* that she actually detains. She asks *may I do this?* We answer *if it is right you may, if it is wrong you may not; let us check it*. This is how SAM allows the student to learn by speaking and the teacher to teach by listening. The word has a high value for the speaker; it is important to the student to be sure that she will be listened carefully. SAM has allowed us to approach the student's ignorance regarding his preferential ways of justifying mathematics that expose her cognitive difficulties.

### **The economic issue: school opposition and resilience**

A discussion of the valorization of effort instead of content is virtually absent from mathematics education research. Typing <"reward effort" "mathematics education" calculus> into Google shows 70 entries, none of which thoroughly discusses, much less advocates rewarding effort. Summative assessment is highly underrepresented in the literature (Cabral & Baldino, 2019b), not even in the Routledge yearbook 2017: Assessment inequalities. As an exception, the possibility of rewarding effort appears *en passant* in Jablonka (2017) as though in a devaluated rise. The system demands that measuring achievement be the only promotional criterion. SAM provides a way to teach inside the system, but not "according" to the system. It is bound to face opposition.

We assign the reason for the absence of effort rewarding studies in mathematics education to the need to *cover up that school is an economic enterprise where the production of qualified-labor-power threatens to become evident* (Baldino & Cabral, 2013). In this sense, the usual requirement of reviewing literature in this eight-page article would cut the space for presenting the new and would corroborate the cover up.

Although a student can spend an entire year in school, going to classes, participating in all the regular activities, if after everything she does not get a certificate, she will not receive anything for all the work she did. On the contrary, those who get the diploma may vaunt their merit of having superseded those who failed. As a commodity, qualified-labor-power has to be sold in the market for higher salaries, otherwise the investment would not be worthwhile. From this perspective, failure is necessary for school functioning, as argued by Baldino and Cabral (1998, 2013). It is because some of us fail that others can achieve higher positions in social hierarchies. The value produced by the ones who flunk is appropriated by the ones who pass. This is the scandal that SAM-in-action threatens to reveal.

### **The years to come**

The dialectical movement that has generated SAM and CTT as opposite poles goes on today in a wide scenario. The hippy movement of the sixties was the first sample. Not only does capitalism penetrate all pores of private life, but it also offers advance role scripts for its eventual opponents (Baldino & Cabral, 2018). What this sort of late capitalism cannot admit to is the demonstration of the dialectical movement from which it emerges as one of the poles. It has to present itself as the only natural truth. In particular, it cannot admit that school is an economic enterprise producing qualified-labor-power. It must hide its truth under a thick layer of priestly teaching and ‘helpful’ mathematics education research that we call CTT.

Therefore, research in SAM for the years to come should aim at eliciting such dialectical movement. SAM is an intervention into capitalist schooling that defines itself in opposition to CTT. Nevertheless, it is not a cosmology or a formula on how school should be. We are not implying that literature on assessment must move beyond content progress evaluations. SAM is not intended to replace CTT; insofar as this could happen, SAM would lose its *raison d'être*. Contrarily to globalized liberal capitalism, SAM recognizes itself as one of the poles generated by the same dialectical socio-historical movement.

# Assessing students' perceptions of democratic practices in the mathematics classroom

Wajeeh Daher

[wajeehdaher@gmail.com](mailto:wajeehdaher@gmail.com)

*Though there exists considerable literature exploring the connections between mathematics education and democratic society, much of this literature is theoretical about what could or should occur. This situation has led some researchers to call for the development of empirical research regarding democratic practices in the mathematics classroom. This paper attempts to advance quantitative empirical research in this area by presenting a questionnaire that examines students' perceptions of four democratic factors: freedom, engagement, equality and justice. The proposed questionnaire is factorable and explains 58.72% of the variance of a more general democracy score. The questionnaire was distributed to 398 ninth grade students, and the data collected was analyzed by computing a one sample t-test to assess participants' scores in relation to the four democratic factors. The results indicated scores are 'less than the good'.*

*Keywords: Democratic practices, mathematics classroom, questionnaire*

## Introduction

Democratic teaching practices may have a positive influence on students' learning outcomes in the mathematics classroom. This may be because successful democratic teaching and learning is conceived as situations where individuals are able to think for themselves, judge independently, and discriminate between good and bad information (Dewey as in Orrill, 2001). Therefore, it is desirable or necessary to enact democratic practices in the mathematics classroom. In addition, such democratic practices need to be assessed to ensure they are appropriately implemented, and to see if they influence specific variables of students' mathematics learning positively (e.g. emotions). One way to assess democratic teaching and learning practices and their relation with other variables is through quantitative methods, with a questionnaire as the main tool. The present research tries to do this and presents a questionnaire to assesses four democratic practices: freedom, equality, engagement and justice in the mathematics classroom.

## Research goals and rationale

Vithal (1999) argues that the literature exploring connections between mathematics education and democratic society is generally theoretical, which indicates the need for research that studies what happens actually in the mathematics classroom regarding this link. Aguilar and Zavaleta (2012) agree with Vithal and point to the need for empirical studies to test and expand such theoretical ideas. The present research offers one step towards providing such empirical research, in that it offers a questionnaire to assess students' perceptions of democratic practices relating to four democracy components: Freedom, engagement, equality and justice. It does so in the context of the Palestinian ninth grade mathematics classroom.

## **Literature review**

Democracy in general is described as consisting of distinct components. Kesici (2008) found that teachers, who adopted democratic practices, talked about democratic classrooms where fair behaviors are demonstrated towards students, students' range of personal freedom is enlarged, and students are provided with equality of opportunity. Thus, Kesici (2008) presents three categories of democracy: fairness, freedom and equality, where fairness can be related to justice and freedom and equality can be related to equity which includes the consideration of individual needs. Regarding equality, Kesici (2008) emphasizes that equality does not mean that teachers should treat all students the same way, but they should give equal opportunity to all students, so to meet their needs.

### **Democracy in the mathematics classroom**

Aguilar and Zavaleta (2012) identified three links between mathematics education and democracy. Firstly, mathematics education can provide students with the skills to analyze critically real life phenomena. Second, the mathematics classroom can encourage values and attitudes essential to building and sustaining democratic societies. Third, mathematics education can function as a social filter that restricts students' opportunities for development and civic participation.

The possible links between mathematics education and democracy have attracted the attention of mathematics education researchers for at least three decades, where different aspects of teaching and learning practices have been studied in the mathematics classroom. Some of these aspects are: authority (Amit & Fried, 2005), students' voice (Daher, 2017; Kaur, Anthony, Ohtani, & Clarke, 2013), the right to equal access to mathematical ideas (Allen, 2011; Ellis & Malloy, 2009), promoting equality (Croom, 1997), promoting democracy (Allen, 2011; Ellis & Malloy, 2009), diversity of curriculum and classroom (Ellis & Malloy, 2009), revisiting old ideas in new ways (Ellis & Malloy, 2009), dialogue (Ball, Goffney, & Bass, 2005; Skovsmose, 1998), proving (Almeida, 2010; Skovsmose, 1998), and engaging in ethnomathematics (Ball et al., 2005; Skovsmose, 1998). This literature has indicated the complexity of the construct of 'democratic practice' in teaching and learning mathematics, which indicates the need for an assessment tool to better understand this construct.

### **Assessing democratic practices in the classroom**

Educational researchers have offered various questionnaires to assess democratic practices in the classroom (Daher & Saifi, 2018; Kubow & Kinney, 2000). For instance, Ahmad, Said, and Jusoh (2015) designed a questionnaire to assess the relationship between democratic classroom practices and students' social skills development. In addition, the tools used to collect data related to democracy in the mathematics classroom have included open ended questions (Daher, 2012) and questionnaires with Likert items (Bulut & Yilmaz, 2014). The questionnaire suggested by Bulut and Yilmaz (2014) consists of a single scale to assess democratic practice. In the present research we suggest a questionnaire that offers multiple factors relating to democratic teaching and learning practices described in the literature.

## Methodology

### Research context and sample

398 Grade 9 students participated in the research. The distribution of these students according to gender and level in math is described in Table 1.

		Level in math					Total
		Poor	acceptable	good	very good	Excellent	
Gender	male	41	34	33	22	10	140
	female	59	65	76	52	6	258
Total		100	99	109	74	16	398

**Table 1: The distribution of the sample according to gender and level in math**

The descriptive statistics of the questionnaire items are given in Table 2.

Item	M	SD	Skew
We can express ourselves freely in the mathematics lesson.	2.84	1.35	.19
We can express our opinion regarding the teacher's presentation.	2.67	1.30	.32
We can express our opinion regarding the teacher's solution methods.	2.70	1.29	.32
We can give different solution methods for a mathematical problem.	2.55	1.47	.281
We can give a faulty solution method for a mathematical problem.	2.46	1.30	.77
The mathematics teacher does not give additional time for solving problems.	3.62	1.34	-.66
The mathematics teacher ignores some students' discussions.	3.39	1.46	-.37
The mathematics teacher does not give the same time to all students to answer questions.	3.08	1.40	-.01
The mathematics teacher does not give the same time to all students during discussions.	3.16	1.31	-.07
The mathematics teacher does not give different solutions to accommodate differences between individual students.	2.92	1.53	.11
The mathematics teacher ignores some students' solutions.	3.41	1.41	-.35
The mathematics teacher encourages us to give new mathematical ideas.	2.58	1.29	.48
The mathematics teacher encourages us to justify our mathematical ideas.	2.48	1.29	.45
The mathematics teacher encourages us to give different answers to a mathematical question.	2.50	1.46	.52
The mathematics teacher encourages us to engage in mathematical discussions.	2.30	1.26	.73
The mathematics teacher encourages us to ask questions.	2.25	1.24	.62
The mathematics teacher does not clarify the reasons for giving marks on the mathematics exam.	3.34	1.20	-.14
I cannot have explanations in the mathematics classroom on the issues that I have not understood.	3.69	1.25	-.61

**Table 2: Means, standard deviations and skewness of the questionnaire items (N=398)**

### Analysis method of the level of democratic behavior scores in the Palestinian ninth grade

To calculate democracy mean scores for the students participating in the research, we computed first grouped frequency distributions (Stockburger, 1998). Then we compared the resulting democracy mean scores with a 'good democracy score' and a 'normal democracy score'. We computed the normal democracy score by dividing 4 by 5 (4 items divided by 5 possible scores where 1 is the lowest score of any item, and 5 is the highest). This resulted in 0.8 which was used to calculate intervals on a scale presented in Figure 1. We considered point (1.8) to be a 'low democracy score', (2.6) to be a 'normal democracy score' and (3.4) to be a 'good democracy score' on this scale. Thus, the scores between 1 and 1.8 were considered 'very low democracy scores', the scores between 1.8 and 2.6 'low democracy scores', the scores between 2.6 and 3.4 'normal democracy scores', the scores between 3.4 and 4.2 'good democracy scores', and the scores between 4.2 and 5 'very good democracy scores'.

**Figure 1: Intervals related to the democracy scores of any item**

To compare the students' mean scores with the 'normal democracy score' and the 'good democracy score' we used a one-sample t-test and compared with the appropriate democracy value.

### Results

Initially, the factorability of the 18 democracy items was examined. Several well recognized criteria for the factorability of a correlation were used. Firstly, it was observed that all the items correlated at least .3 with at least one other item, suggesting reasonable factorability. Secondly, the Kaiser-Meyer-Olkin measure of sampling adequacy was .89, above the commonly recommended value of .6, and Bartlett's test of sphericity was significant ( $\chi^2(153) = 2562.90$ ,  $p < .001$ ). The diagonals of the anti-image correlation matrix were also all over .5. Finally, the communalities were all above .4, further confirming that each item shared some common variance with other items. Given these overall indicators, factor analysis was deemed to be suitable with all 18 items.

Table 3 presents factor loadings based on rotated principal components analysis with Oblimin rotation for 18 items from the above scale ( $N = 218$ ).

Principal component analysis was used because the primary purpose was to identify and compute composite scores for the factors underlying the scale. Initial eigenvalues indicated that the first four factors explained 33.56%, 9.96%, 7.81% and 7.39% of the variance respectively. The fifth factor had an eigenvalue 5.02, while the other factors (from the sixth to the eighteenth) explained less than 4% of the variance.
